You can distinguish even from odd isometries in three dimensions, as in two, by their effects on oriented figures. Informally, you can consider left- and right-hand gestures. Formally, consider tetrahedra—section 3.10 defined them as *ordered* quadruples of noncoplanar points. In figure 7.2.2, the vertices of tetrahedron *PQRS* are arranged as you might point with your right thumb, with P on the thumb, and ΔQRS oriented as your fingers are curled. The reflection across the plane maps them to points P' to S', arranged like the corresponding left-hand gesture. There are twenty-four tetrahedra with vertices P to S listed in various orders. Using the figure, you can classify them according to your intuitive notion of orientation:

Class $\mathscr{R}$: *PQRS*, *PRSQ*, and ten others;
Class $\mathscr{L}$: *PQSR*, *PRQS*, and ten others.

How can you distinguish these classes mathematically, without relying on the figure and your intuition? The determinant formula for tetrahedral

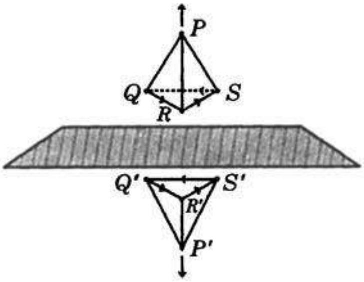

Figure 7.2.2
Reflection across a plane reverses orientation.

volume, theorem 5.6.10, provides the tool. These tetrahedra all have the same volume: ±1/6 times each of the determinants

$$\mathscr{R}\colon\ \det[P-R, Q-R, S-R],\ \det[P-S, R-S, Q-S], \ldots$$
$$\mathscr{L}\colon\ \det[P-S, Q-S, R-S],\ \det[P-Q, R-Q, S-Q], \ldots.$$

You can show that the determinants in the first class are all equal to the same value; and all those in the second, to its negative. Thus all those in one class have the same *positive* determinant; the others have the same *negative* determinant. Accordingly, you can call the tetrahedra *positively* or *negatively* oriented. (*Which* class of tetrahedra is positive depends on the standard coordinate system that you chose at the onset of this chapter. If you reverse the scale on any one axis, you'll interchange the positive and negative classes.) The following computation shows that an even isometry $X \to X' = AX + B$ preserves a tetrahedron's orientation, whereas an odd one reverses it:

$$\begin{aligned}
&\det[P'-R', Q'-R', S'-R'] \\
&\quad = \det[(AP+B)-(AR+B), (AQ+B)-(AR+B), \\
&\qquad\qquad (AS+B)-(AR+B)] \\
&\quad = \det[AP-AR,\ AQ-AR,\ AS-AR] \\
&\quad = \det[A(P-R), A(Q-R), A(S-R)] \\
&\quad = \det(A[P-R, Q-R, S-R]) \\
&\quad = (\det A)(\det[P-R, Q-R, S-R]) \\
&\quad = \pm\det[P-R, Q-R, S-R].
\end{aligned}$$

7.3 Translations and rotations

Concepts

- Translations
- Conjugate translations
- Rotations
- Angle parameters for rotations
- Conjugate rotations
- Commuting reflections
- Half turns

The previous section introduced three-dimensional reflections, and showed that each three-dimensional isometry is the identity, a reflection, or the composition of two, three, or four reflections. Section 7.2 studies the compositions of *two* reflections in detail. They're the translations and the rotations.

Translations

Translations are handled in three dimensions exactly as in the plane. The translation corresponding to a vector V is the transformation $\tau_V : X \rightarrow X' = X + V$ displayed in figure 7.3.1 on the preceding page. (This is just the corresponding two-dimensional figure 6.2.1 with a third axis inserted.) The following theorem summarizes some main facts about translations. You can prove it just as you proved the analogous planar results in sections 6.2 and 6.4.

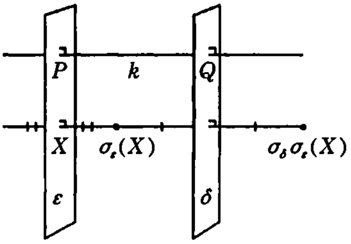
Theorem 1. Composition of translations corresponds to vector addition: For any vectors V and W, $\tau_V \tau_W = \tau_{V+W}$ and $\tau_V^{-1} = \tau_{-V}$. Moreover, $\tau_O = \iota$. Therefore, the translations form a subgroup of the isometry group.

Just as in two dimensions, you can construct translations from reflections.

Theorem 2. The composition $\sigma_\delta \sigma_\varepsilon$ of reflections across parallel planes δ and ε is the translation τ with vector $2(P - Q)$, where P and Q are the intersections of δ and ε with any line k perpendicular to δ and ε.

Proof. Verify that $\sigma_\delta \sigma_\varepsilon(X) = \tau(X)$ for four noncoplanar points X, as in figure 7.3.2, then apply the uniqueness theorem. ♦

Figure 7.3.2 $\sigma_\delta\sigma_\varepsilon$ is a translation when $\delta \parallel \varepsilon$.



The conjugacy properties of three-dimensional translations are also analogous to the results for plane transformations. Theorem 3 is in fact *identical* to theorem 6.9.9.

Theorem 3. The conjugacy class of a translation τ whose vector has length t consists of all translations with vectors of length t. If τ and an isometry φ have equations $\tau: X \to X' = X + T$ and $\varphi: X \to X' = AX + B$ with respect to a single coordinate system, then $\varphi\tau\varphi^{-1}$ is the translation with vector AT.

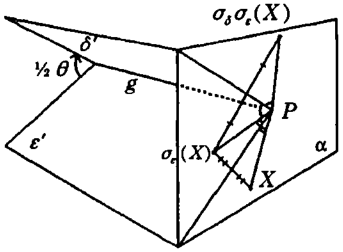
Proof. The first sentence follows directly from the conjugacy theorem. The proof of the second is the same as that of theorem 6.9.9. ♦

Rotations

Pursuing the analogy with the theory of plane isometries, you'll next ask what's the composition $\sigma_\delta\sigma_\varepsilon$ of the reflections across two distinct *intersecting* planes δ and ε. It's called a *rotation* about its *axis* $g = \delta \cap \varepsilon$. The following theorem justifies this terminology. To prove it, apply theorem 7.2.1.

Theorem 4. Consider distinct planes δ and ε through a line g perpendicular to a plane α. (See figure 7.3.3.) Choose an angular scale on α with center $P = \alpha \cap g$. Choose half planes δ' and ε', each with edge g. If rays $\alpha \cap \delta'$ and $\alpha \cap \varepsilon'$ have angle parameters ζ and η, then the restriction of $\rho = \sigma_\delta\sigma_\varepsilon$ to α is the (two-dimensional) rotation of α about P with angle parameter $\theta = 2(\eta - \zeta)$. The fixpoints of ρ constitute its axis g.

Figure 7.3.3
$\sigma_\delta\sigma_\varepsilon$ is a rotation when δ intersects ε.



In theorem 4 you can choose δ' and ε' in four ways. Another choice might add 180° to ζ and/or η. Since angle parameters are determined only mod 360°, your choice has no effect on θ. Since θ depends only on the *difference* of two parameters, it depends only on ρ and the *orientation* of the angular scale. You can specify orientation by designating a ray on g as positive. (Informally, align it with your thumb when the knuckles and fingertips of your right fist fall along rays with zero and positive angle parameters.)

For theoretical considerations it's best to describe a rotation as a specific composition of plane reflections. For practical computations, however, it's often helpful to specify a positive axial ray and an angle parameter. For example, a rotation with angle parameter θ about one of the three coordinate axes fixes that coordinate of each point X, and operates on its other coordinates like the corresponding two-dimensional rotation about the origin. For the first coordinate axis, the rotation has equations

$$\begin{aligned} x_1' &= x_1 \\ x_2' &= x_2 \cos\theta - x_3 \sin\theta \\ x_3' &= x_2 \sin\theta + x_3 \cos\theta \end{aligned} \qquad X' = AX \qquad A = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos\theta & -\sin\theta \\ 0 & \sin\theta & \cos\theta \end{bmatrix}.$$

The analogous rotations about the second and third axes have matrices

$$\begin{bmatrix} \cos\theta & 0 & -\sin\theta \\ 0 & 1 & 0 \\ \sin\theta & 0 & \cos\theta \end{bmatrix} \qquad \begin{bmatrix} \cos\theta & -\sin\theta & 0 \\ \sin\theta & \cos\theta & 0 \\ 0 & 0 & 1 \end{bmatrix}.$$

For other axes, the matrices have no such obvious form. In practice, if you must compute with the matrix of a rotation, you generally choose one of the coordinate axes as the rotational axis.

It's harder to phrase results about conjugacy and rotations in three dimensions than it was in the plane theory, because the angles are harder to describe. It seems easiest to use the next theorem to refer angle questions back to the planes whose reflections combine to form a rotation.

Theorem 5. Suppose line g is the intersection of planes δ and ε. Consider the rotation $\rho = \sigma_\delta \sigma_\varepsilon$ and an isometry φ. Then $\varphi\rho\varphi^{-1}$ is the rotation $\sigma_{\varphi[\delta]}\sigma_{\varphi[\varepsilon]}$ with axis $\varphi[g]$. A rotation is conjugate with ρ just in case it's the composition of the reflections across planes ζ and η that form a dihedral angle whose measure is the same as that of one of those formed by δ and ε.

Proof. $\varphi\rho\varphi^{-1} = \varphi\sigma_\delta\sigma_\varepsilon\varphi^{-1} = \varphi\sigma_\delta\varphi^{-1}\varphi\sigma_\varepsilon\varphi^{-1} = \sigma_{\varphi[\delta]}\sigma_{\varphi[\varepsilon]}$. You can check that the stated condition on ζ and η is equivalent to the existence of an isometry φ such that $\varphi[\delta] = \zeta$ and $\varphi[\varepsilon] = \eta$. ♦

When do two reflections commute? What's their composition in that case? To answer those questions, you can prove the following corollary of theorems 2 and 4. It's similar to the solution of the corresponding two-dimensional problem.

Theorem 6. Reflections σ_δ and σ_ε commute just when planes δ and ε are equal or perpendicular. In the former case, $\sigma_\delta \sigma_\varepsilon$ is the identity. In the latter, it's self-inverse but not the identity. Its restriction to a plane perpendicular to its axis is a (two-dimensional) half turn.

A self-inverse three-dimensional rotation that's not the identity is called the *half turn* about its axis g, and it's denoted by σ_g.[2] Several exercises in section 7.7 examine half turns in detail. Exercise 21 derives the equation of σ_g in terms of the equation of g.

7.4 Glide and rotary reflections

Concepts
- Commuting translations and reflections
- Glide reflections
- Commuting rotations and reflections
- Rotary reflections
- Reflections across points

Previous sections have analyzed reflections, and compositions of two reflections—that is, translations and rotations. What kind of isometry is a composition of three reflections? It's either the composition of a translation with a reflection, or of a rotation with a reflection. The next two headings describe these possibilities in turn. Each one asks first, when is the order of these components significant?

Glide reflections

Theorem 1. A translation τ_V commutes with the reflection σ_ε across a plane ε just when $V = O$ or $\overrightarrow{OV} \parallel \varepsilon$.

Proof. You can easily verify that $\sigma_\varepsilon \tau_V$ and $\tau_V \sigma_\varepsilon$ coincide under either condition. To show that they differ when neither condition holds, consider what they do to a point on ε. ♦

---

[2] Some authors call σ_g the *reflection across* g.

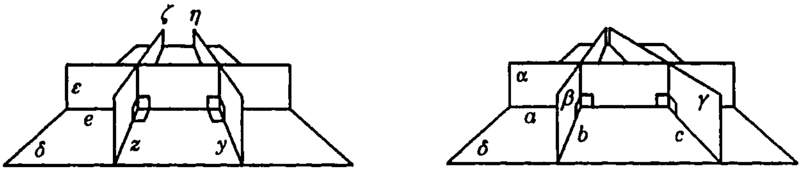


Figure 7.4.1 Proving theorem 2

When $V = O$ or $\overrightarrow{OV} \parallel \varepsilon$, the composition $\varphi = \sigma_\varepsilon \tau_V$ is called a *glide reflection*. The translational component is uniquely determined by φ because $\varphi\varphi = \tau_{2V}$. By decomposing the translational component into reflections across planes ζ and η, you can see that $\varphi = \sigma_\varepsilon \sigma_\zeta \sigma_\eta$ is a glide reflection when $\varepsilon \perp \zeta, \eta$ and $\zeta \parallel \eta$. (See the left-hand diagram of figure 7.4.1—ignore plane δ.) The reflectional component of φ is unique, too, because its mirror is the set of midpoints $\frac{1}{2}(X + \varphi(X))$ for all X. A glide reflection has no fixpoint unless it's a reflection.

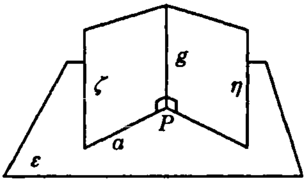
Theorem 2. If planes α, β, and γ have a common perpendicular plane δ, then $\sigma_\alpha \sigma_\beta \sigma_\gamma$ is a glide reflection.

Proof. Let $a = \alpha \cap \delta$, $b = \beta \cap \delta$, and $c = \gamma \cap \delta$, as in the right-hand diagram of figure 7.4.1. By theorem 7.2.1, each of σ_α, σ_β, and σ_γ fixes δ, and they operate on a point X in δ in the same way as the two-dimensional reflections of δ across a, b, and c, respectively. Thus, $\varphi = \sigma_\alpha \sigma_\beta \sigma_\gamma$ affects X in the same way as the composition of three two-dimensional reflections. By the theory of plane isometries, that's a two-dimensional glide reflection. Therefore, there exist lines e, z, and y in δ such that $e \perp z$, $e \perp y$, and φ operates on points in δ in the same way as the composition of its two-dimensional reflections across e, z, and y. Construct planes ε, ζ, and η perpendicular to δ through e, z, and y, as in the left-hand diagram of figure 7.4.1. Each of σ_ε, σ_ζ, and σ_η fixes δ, and they affect points in δ in the same way as the two-dimensional reflections of δ across e, z, and y, respectively. That is, $\varphi(X) = \sigma_\varepsilon \sigma_\zeta \sigma_\eta(X)$ for all X in δ. Thus, the even isometry $\sigma_\eta \sigma_\zeta \sigma_\varepsilon \varphi$ fixes each point in δ. By theorem 7.2.3, it's the identity, so $\varphi = \sigma_\varepsilon \sigma_\zeta \sigma_\eta$. This is a glide reflection, since $\sigma_\zeta \sigma_\eta$ is a translation τ_V with $V = O$ or $\overrightarrow{OV} \parallel \varepsilon$. ♦

Rotary reflections and inversions

Next, consider compositions of *rotations* and reflections. When is the order of the components significant? The following theorem says when it's *not*. Its proof, similar to that of theorem 1, is exercise 7.9.2.

Figure 7.4.2
Proving theorem 4



Theorem 3. A rotation ρ commutes with a reflection σ_ε just when $\rho = \iota$, or its axis g is perpendicular to ε, or it's a half turn about a line in ε.

When $\rho = \iota$ or ρ is a rotation with axis perpendicular to ε, the composition $\varphi = \sigma_\varepsilon \rho$ is called a *rotary reflection*. By decomposing the rotational component into reflections across planes ζ and η, you can see that $\varphi = \sigma_\varepsilon \sigma_\zeta \sigma_\eta$ is a rotary reflection when $\varepsilon \perp \zeta, \eta$ and ζ intersects η, as in figure 7.4.2. Clearly, φ has either a plane ε of fixpoints, or exactly one fixpoint P, called the *center* of φ. In the first case, $\varphi = \sigma_\varepsilon$. In the second, if φ isn't self-inverse, it has exactly one fixed plane ε —its *mirror*—which consists of all points of the form $\frac{1}{2}(X + \varphi(X))$. In that case, φ also determines its rotational component uniquely, since $\rho = \sigma_\varepsilon \varphi$.

However, a self-inverse rotary reflection has no unique mirror or rotational component. This situation occurs when $\zeta \perp \eta$ in figure 7.4.2. Then, φ is a composition of reflections across three mutually perpendicular planes. It's called the *reflection* σ_P *across center* $P = g \cap \varepsilon$.[3] The next result justifies that terminology—the point reflection depends only on P, not on g or ε. You can supply the proof. See exercises 7.7.7, 7.7.8, and 7.7.10 for a more detailed study of point reflections.

Theorem 4. The reflection σ_P across a point P is self-inverse, and $P = \frac{1}{2}(X + \varphi(X))$ for every point X, so $\varphi(X) = 2P - X$. If ε is any plane through P and g is the line through P perpendicular to ε, then $\sigma_P = \sigma_\varepsilon \sigma_g$.

The next result shows that a composition of three reflections is a rotary reflection, unless theorem 2 has classified it already as a glide reflection.

Theorem 5. If planes α, β, and γ have no common perpendicular plane, then $\sigma_\alpha \sigma_\beta \sigma_\gamma$ is a rotary reflection.

Proof. You can show that $h = \beta \cap \gamma$ is a line. Erect plane $\delta \perp \alpha$ through h, then find plane η through h such that $\sigma_\beta \sigma_\gamma = \sigma_\delta \sigma_\eta$ (by making two dihedral angles have equal measure). Erect plane $\varepsilon \perp \eta$ through the line $a = \alpha \cap \delta$, then find plane $\zeta \perp \varepsilon$ through a. (See figure 7.4.2.) It follows that $\sigma_\alpha \sigma_\beta \sigma_\gamma = \sigma_\alpha \sigma_\delta \sigma_\eta = \sigma_a \sigma_\eta = \sigma_\varepsilon \sigma_\zeta \sigma_\eta$. This isometry is a rotary reflection because $\sigma_\zeta \sigma_\eta$ is a rotation with axis $g = \zeta \cap \eta$ perpendicular to ε. ♦

---

[3] Some authors call σ_P the *inversion* with center P, but that usage conflicts with the notion of inversion with respect to a circle or sphere.

7.5 Classifying isometries

Concepts

Commuting translations and rotations
Screws
Classification

According to the structure theorem, each isometry is the identity, a reflection across a plane, or a composition of reflections across two, three, or four planes. In section 7.2 you studied reflections. Section 7.3 was devoted to compositions of two reflections: the translations and rotations. And section 7.4 described compositions of three: the glide and rotary reflections. This section covers the last case, compositions of four reflections. Then it summarizes the entire classification scheme.

Screws

A composition of four reflections could be a translation or a rotation. But there's one more type, whose description is facilitated by the next theorem. Its proof, which resembles those of theorems 7.4.2 and 7.4.4, is exercise 7.9.3.

Theorem 1. A translation τ_V commutes with a rotation ρ just when $V = O$, $\rho = \iota$, or $\vec{OV}$ is parallel to the axis g of ρ.

When τ_V commutes with ρ, the composition $\varphi = \rho\tau_V$ is called a *screw*. A screw determines its rotational and translational components ρ and τ_V uniquely. If it's neither a rotation nor a translation, then φ has no fixpoints but exactly one fixed line g, $V = \varphi(P) - P$ for any point P on g, and $\rho = \varphi\tau_V^{-1}$.

The next result seems like a special case, but Hermann Wiener showed in 1890[4] that it provides the key to identifying any composition of four reflections.

---

[4] Wiener 1890–1893, part II.

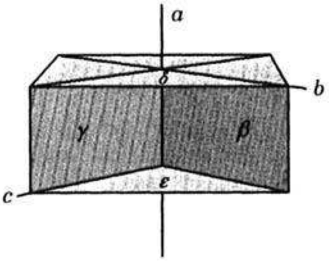


Figure 7.5.1
Proving lemma 2

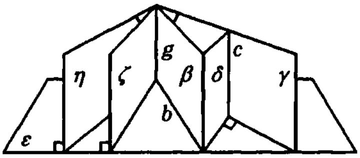

Figure 7.5.2
Proving theorem 3

Lemma 2. For any lines b and c, the composition $\varphi = \sigma_b \sigma_c$ is a screw.

Proof. This argument is designed to apply when b and c are skew (see figure 7.5.1). You can verify that it also works when they're coplanar. (You'll need additional figures for the parallel and intersecting cases.) First, find a line a perpendicular to b and c, plane β through a and b, and plane γ through a and c. Erect planes $\delta \perp \beta$ through b and $\varepsilon \perp \gamma$ through c. Then $\delta \perp \gamma$ also, so $\sigma_b \sigma_c = (\sigma_\beta \sigma_\delta)(\sigma_\gamma \sigma_\varepsilon) = (\sigma_\beta \sigma_\gamma)(\sigma_\delta \sigma_\varepsilon)$. This is a screw because $\sigma_\beta \sigma_\gamma$ is a rotation with axis a and $\sigma_\delta \sigma_\varepsilon$ is a translation parallel to a. ♦

Theorem 3. Every even isometry φ is a screw.

Proof. Suppose φ is neither a translation nor a rotation. Then there exist distinct points P and Q such that $\varphi(P) = Q$. Let δ be the perpendicular bisector of segment $\overline{PQ}$, so that $\varphi\sigma_\delta(Q) = Q$. Since $\varphi\sigma_\delta$ is odd, it's a composition of three reflections. Since it has a fixpoint, it's a rotary reflection, and $\varphi\sigma_\delta = \sigma_\varepsilon \sigma_\zeta \sigma_\eta$ for some planes ε, ζ, and η such that $\varepsilon \perp \zeta, \eta$. The intersection $g = \zeta \cap \eta$ is a line; otherwise, $\varphi\sigma_\delta = \sigma_\varepsilon$, and φ would equal $\sigma_\varepsilon \sigma_\delta$, a rotation or translation. Erect the plane $\gamma \perp \delta$ through g, as shown in figure 7.5.2. Find the plane β through g such that $\sigma_\zeta \sigma_\eta = \sigma_\gamma \sigma_\beta$ (by making two dihedral angles have equal measure). Then $\varepsilon \perp \beta$ also, hence $\varphi = \varphi\sigma_\delta\sigma_\delta = \sigma_\varepsilon \sigma_\zeta \sigma_\eta \sigma_\delta = \sigma_\varepsilon \sigma_\gamma \sigma_\beta \sigma_\delta = \sigma_c \sigma_b$, where $b = \beta \cap \delta$ and $c = \gamma \cap \varepsilon$. By lemma 2, this is a screw. ♦

Hermann WIENER was born in 1857 in Karlsruhe. His father Christian Wiener was Professor of Descriptive Geometry at the Technical Institute there. His younger brother Otto became a physicist, noted for work on the wave theory of light.

Wiener began university studies at Karlsruhe, but completed his Ph.D. at München in 1880 with a dissertation on plane curves. His training was influenced significantly by Felix Klein, a close collaborator at München with Wiener's cousin Alexander Brill. In 1880, Klein moved to Leipzig, and Wiener followed. After a year, though, he returned to Karlsruhe as assistant to his father. He continued research, and obtained a lecturer position in the university at Halle in 1885.

There Wiener wrote a series of research papers that clarified the relationships of several fundamental theorems and techniques in Euclidean and projective geometry, including Desargues' theorem and the use of self-inverse transformations. He made the first extensive use of calculations with reflections, like those in this and the preceding chapter. He regarded this calculus as an algebra of *geometric* objects, in contrast to the algebra of *numbers* used in coordinate geometry.

Wiener also pioneered the abstract axiomatic approach to geometry, emphasizing its usefulness, but he never built a complete theory. Hilbert's famous remark that he could regard geometry as a theory of tables, chairs, and bar stools just as well as one of points, lines, and planes stemmed from his excitement after hearing a lecture by Wiener in 1890. That took place in Halle at the first meeting of the German Mathematical Society. Wiener was one of the original members.

In 1894 Wiener became Professor of Mathematics at the technical university in Darmstadt, where he remained until he retired in 1927. Darmstadt lay outside the mainstream, and Wiener never continued his major research work. In 1911 he revised and marketed a set of geometric models originally developed by his father; they came into widespread use in secondary and technical school instruction. Wiener served his university well—he was elected Dean of his faculty for two terms. He died in 1939.

Wiener's results were extended and incorporated into major works on foundations of geometry for the next sixty years. In particular, crucial steps in the work of Hilbert, Thomsen, and the present author were established or proposed originally by Hermann Wiener.

Classification theorem

You've now completed the analysis of compositions of reflections. The following theorem refines and summarizes the classification begun with the structure theorem.

---

[5] Wiener 1890–1893.

[6] See Reid 1970, chapter 8.

***Theorem 4* (*Classification theorem*).** A three-dimensional isometry is

(0) the identity ι, or
(1) the reflection σ_ε across a plane ε, or
(2a) a translation τ_V with vector $V \neq O$, or
(2b) a rotation $\rho \neq \iota$, or
(3a) a glide reflection $\sigma_\varepsilon \tau_V$ with mirror ε and vector $V \neq O$, or
(3b) a reflection across a point P, or
(3c) a rotary reflection $\sigma_\varepsilon \rho$ with mirror ε and rotational component ρ that's not self-inverse, or
(4) a screw $\rho \tau_V$ with rotational component $\rho \neq \iota$ and vector $V \neq O$.

These classes are disjoint.

You might like to provide a table of fixed points, lines, and planes for each of the eight isometry types listed in the classification theorem, analogous to those after corollary 6.9.2 and in exercise 6.11.12.

Finding fixpoints, fixed lines, and fixed planes of an isometry $\varphi : X \to X'$ when you know its equation $X' = AX + B$ is a substantial exercise in solving possibly singular linear systems. You'll find examples under the heading **Exercises on equations** in section 7.7. The practical details of those computations tend to differ considerably from those of the theory presented so far. They're outlined in some paragraphs that precede the exercises.

Section 6.9 applied the classification of plane isometries to describe rotations and translations in more detail. It also pursued the notion of conjugacy beyond the level achieved by theorems 7.2.5, 7.3.3, and 7.3.5. For analogous three-dimensional studies, see the **Conjugacy exercises** heading in section 7.7.

7.6 Similarities

Concepts

Complete analogy with the two-dimensional theory
Hometheties and homothetic rotations
Classification theorem

You could really write this section on three-dimensional similarities yourself. Their theory is entirely analogous to its plane counterpart. Except for its main result, the classification theorem, this section just makes the necessary adjustments to the definitions and theorem statements. You can adapt every proof in section 6.10 to work in three dimensions.

A *similarity with ratio* r is a transformation $\psi : P \to P'$ of the set of all points, such that $P'Q' = r\,(PQ)$ for all P and Q. As an example, select any point Z and consider the transformation $\varphi_{r,Z} : P \to P'$ such that $Z' = Z$ and for $P \neq Z$, P' is the point on $\overrightarrow{ZP}$ with $ZP' = r\,(ZP)$. If $r = 1$, then $\varphi_{r,Z}$ is the identity; if $r < 1$ or $r > 1$, it's called a *contraction* or *dilation about* Z.

A similarity ψ: $X \to X'$ with ratio r leaves invariant angle measure, betweenness, and any geometric property that you can define in terms of them. In particular, ψ is a collineation, and the image of a plane is a plane. The image of a circle or sphere with radius t is a circle or sphere with radius rt. That of a triangle with area s is a similar triangle with area $r^2 s$. And the image of a tetrahedron with volume v is a similar tetrahedron with volume $r^3 v$.

A composition of similarities with ratios r and s is a similarity with ratio rs. The inverse of a similarity with ratio r is a similarity with ratio r^{-1}. Therefore, the similarities form a transformation group that contains the isometries.

The section 6.10 proof of the fixpoint theorem was chosen specifically to apply to the three-dimensional case as well: Unless a similarity ψ is an isometry, it has exactly one fixpoint.

The uniqueness theorem takes a slightly different form in three dimensions: Similarities χ and ψ coincide if $\chi(X) = \psi(X)$ for *four noncoplanar* points X. This follows from the fixpoint theorems, since $\chi\psi^{-1}$, a similarity with four noncoplanar fixpoints, must be an isometry, hence the identity.

A similar argument shows that every similarity $\psi : X \to X'$ is the composition of an isometry and a dilation or contraction with the same ratio r and arbitrarily chosen center, so that ψ has an equation $X' = rAX + B$ with an orthogonal matrix A. Moreover, ψ determines A and B uniquely, and every such equation defines a similarity. Since ψ preserves orientation just in case the isometry $X \to AX$ does, ψ is termed *even* or *odd* depending on whether $\det A = +1$ or -1.

The similarities $\varphi_{r,Z}$ and $\varphi_{r,Z}\,\sigma_Z$ are called *homotheties* with center Z. A composition of one of these with a rotation about an axis through Z is called a *homothetic rotation*. If ψ is a similarity but not an isometry, then it has a fixpoint Z. Define $\chi = \psi\varphi_{r^{-1},Z}$ or $\chi = \psi\sigma_Z\varphi_{r^{-1},Z}$ depending on whether ψ is even or odd, so that χ is an even isometry with fixpoint Z and $\psi = \chi\varphi_{r,Z}$ or $\chi\varphi_{r,Z}\sigma_Z$. By theorem 7.5.4, χ is a rotation about an axis through Z, so ψ is a homothetic rotation. This proves

Theorem 1 **(*Classification theorem*).** A similarity is an isometry or a homothetic rotation.

7.7 Exercises

Concepts

Distance-preserving functions
Dilatations
Compositions of commuting point and plane reflections and half turns
Conjugates
Compositions of reflections, translations, and rotations
Classifying isometries and similarities, given their equations
Finding fixpoints and fixed lines of isometries, given their equations
Reflection calculus
Three-reflections theorems

This section contains thirty-two exercises related to the material covered earlier in this chapter. The first three ask for some straightforward proofs omitted earlier. Several others, listed under the headings **Commuting reflections and half turns**, **Conjugacy exercises**, and **Classifying isometries**, extend the chapter's methods beyond the essentials covered earlier, and provide a nearly complete treatment of the interrelationships among reflections, translations, and rotations. The conjugacy exercises firmly establish results you'll often find used without mention in applications. The exercises under the heading **Exercises on equations** familiarize you with the algebraic and numerical computations often required to apply the theory. Some require tedious arithmetic to evaluate determinants and solve linear systems. There was no effort to avoid that. You're expected to use mathematical software for that work. Finally, exercises 5 and 6 and those under the heading **Reflection calculus** provide excursions into areas less central to the program of this book. You've already met their two-dimensional counterparts in chapter 6.

General exercises

Exercises 1 to 3 ask for several proofs omitted from earlier sections of this chapter.

Exercise 1. Prove theorem 7.1.4: The only isometry with four noncoplanar fixpoints is the identity. *Suggestion* : Imitate the proof of theorem 6.2.7.

Exercise 2. Prove theorem 7.4.3: A rotation ρ commutes with a reflection σ_ε just when $\rho = \iota$, or its axis g is perpendicular to the mirror ε, or it's a half turn about a line in ε. *Suggestion* : Imitate the proof of theorem 7.4.1.

Exercise 3. Prove theorem 7.5.1: A translation τ_V commutes with a rotation ρ just when $V = O$, $\rho = \iota$, or $\vec{OV}$ is parallel to the axis of ρ. *Suggestion*: Imitate the proofs of theorems 7.4.2 and 7.4.4.

Exercise 4 is the three-dimensional analog of exercise 6.11.8.

Exercise 4. Show that an isometry φ is even if and only if $\varphi = \chi\chi$ for some isometry χ.

Exercises 5 and 6 pursue excursions into less central themes, already begun in two-dimensional exercises under the section 6.11 headings **Exercises on the definitions of isometry and similarity** and **Dilatations**. If you've solved those in the most efficient way, you should need little to adapt your work to three dimensions.

Exercise 5. Formulate and prove three-dimensional versions of exercises 6.11.40–6.11.41 on the definitions of isometry and similarity.

Exercise 6. Formulate and prove three-dimensional analogs of exercises 6.11.42–6.11.45 on dilatations.

Commuting reflections and half turns

The conditions in plane geometry under which reflections and half turns commute—the nontrivial self-inverse isometries—were laid out at the end of section 6.3. Those ideas played essential roles in the rest of that chapter. In three-dimensional geometry there are *three* types of nontrivial self-inverse isometries. A complete treatment of their commutativity would have clogged the earlier sections of this chapter unacceptably, so they covered only a few aspects. In fact, the theory in this chapter was streamlined to allow that omission. But its *applications* require *all* the commutativity details, so they're presented here systematically, as exercises.

Exercise 7. Show that the composition $\sigma_P \sigma_Q$ of two point reflections is the translation with vector $2(P - Q)$, and they don't commute unless $P = Q$.

Exercise 8. Show that point and plane reflections σ_P and σ_ε commute just when P lies on ε, and in that case $\sigma_P \sigma_\varepsilon$ is the half turn about the line $g \perp \varepsilon$ through P.

Exercise 9. Show that

Part 1. a half turn σ_g commutes with a plane reflection σ_ε if and only if g lies in ε or $g \perp \varepsilon$;

Part 2. if g lies in ε, then $\sigma_g \sigma_\varepsilon$ is the reflection across the plane perpendicular to ε through g;

Part 3. if $g \perp \varepsilon$, then $\sigma_g \sigma_\varepsilon$ is the reflection across $g \cap \varepsilon$.

Exercise 10. Show that a point reflection σ_P and a half turn σ_g commute if and only if P lies on g, and in that case $\sigma_P \sigma_g$ is the reflection in the plane $\varepsilon \perp g$ through P.

Exercise 11. Show that half turns σ_g and σ_h about distinct lines g and h commute if and only if $g \perp h$, and in that case, $\sigma_g \sigma_h$ is the reflection across the intersection of g and h.

Conjugacy exercises

The conjugacy classes of two-dimensional isometries were described in complete detail under that heading in section 6.9. That information is important for applications, because authors often handle, for example, all 60° rotations interchangeably without mentioning explicitly the conjugacy relation that connects them. The same is true in three-dimensional applications. Earlier sections of chapter 7 contained the most essential conjugacy results: the general ideas near the end of section 7.1, and theorems 7.2.5, 7.3.3, and 7.3.5. Further results were omitted because their proofs are unwieldy and repetitive. They're offered here as exercises.

Exercise 12 shows that, like the plane reflections, the half turns and point reflections each constitute single conjugacy classes.

Exercise 12. Show that $\varphi \sigma_P \varphi^{-1} = \sigma_{\varphi(P)}$ and $\varphi \sigma_g \varphi^{-1} = \sigma_{\varphi[g]}$ for any point P, any line g, and any isometry φ. *Suggestion*: Consider fixpoints!

Exercise 13. Describe the conjugacy class of a glide reflection.

Exercise 14. Describe the conjugacy class of a rotary reflection.

Exercise 15. Describe the conjugacy class of a screw.

Classifying isometries

Earlier in this chapter, a glide reflection was defined as a composition of a translation and a commuting plane reflection, a rotary reflection as a composition of a rotation and a commuting plane reflection, and a screw as a composition of a translation and a commuting rotation. With these notions, you can classify *all* isometries. Exercises 16 to 18 give you some practice. What kinds of isometries are the analogous compositions whose components *don't* commute?

Exercise 16. What's the composition of a translation and a plane reflection when they don't commute?

Exercise 17. What's the composition of a rotation and a plane reflection when they don't commute?

Exercise 18. What's the composition of a translation and a rotation when they don't commute?

Exercises 16 to 18 don't cover the *whole* subject of commutativity. When do isometries of the various *other* types commute, and what are their compositions? Most of the combinations are too rare to warrant special treatment—except one: the composition of two rotations. In two dimensions its description is simple; see theorem 6.9.3. In three, that's not true unless the rotations commute. Exercise 19 investigates the situation.

Exercise 19. When do two rotations commute? What's their composition in that case and in general?

Exercises on equations

As in two-dimensional transformational geometry, the theory of isometries in three dimensions seems very different from the practice of computing with them. That's the effect of streamlining to present the essential details of the theory efficiently, in a form that's easy to remember. The exercises under this heading present the computational details. In the first two, closely related to two-dimensional exercise 6.11.25, you derive equations for plane reflections and half turns in terms of the equations of their mirrors and axes.

Exercise 20. Consider a point $P = \langle p_1, p_2, p_3 \rangle \neq O$ and the plane $\delta \perp \overset{\to}{OP}$ through O. Show that σ_δ has matrix

$$A = I - \frac{2}{P^tP}K,$$

where $K = PP^t$. Now consider the plane $\varepsilon \perp \overset{\to}{OP}$ through a point Q. Show that $\sigma_\varepsilon : X \to X'$ has equation

$$X' = AX + \frac{2}{P^tP}KQ.$$

Exercise 21. Find an equation for the half turn $X \to X'$ about the line g with parametric equations $X = tP + Q$. *Suggestion*: Use the matrix $K = PP^t$ introduced in exercise 20.

In the next two exercises, you start from geometric descriptions of certain isometries and find their equations. These involve very tedious computations. Use mathematical software wherever possible!

Exercise 22. Find equations for

(a) the reflection across the plane ε with equation $x_1 + 2x_2 + 3x_3 = 4$;

(b) the glide reflection with mirror ε and vector $<3,-2,1/9>$;

(c) the half turn about the line through points $<1,1,2>$ and $<2,1,1>$.

Exercise 23. Consider the plane ε in exercise 22, its intersections P, Q, and R with the coordinate axes, and the line $g \perp \varepsilon$ through Q. Find equations for

(a) the rotation $\rho : X \to X'$ about g that maps $\vec{QR}$ to $\vec{QP}$, with coefficients accurate to four decimal places;

(b) the rotary reflection $\rho\sigma_\varepsilon$.

Suggestion: The equation has the form $X' = AX + B$ for some matrix A and some vector B. Find four points X, no three of which are coplanar, for which you know X'. From the four equations $X' = AX + B$ construct a system of twelve linear equations for the twelve entries of A and B, then solve it.

The final two exercises under this heading ask you to classify an isometry or similarity, given its equation. To *classify* an isometry,

- identify its class among those listed in the classification theorem;
- find an equation for its mirror—if it has one;
- find its vector—if it has one;
- find an equation for its axis—if it has one—and specify a vector to indicate a positive ray, then find a corresponding angle parameter.

To complete a classification, you may need to find fixpoints or fixed lines of an isometry $\varphi : X \to X' = AX + B$. For a fixpoint, you'll have to solve the linear system $X = X'$ —that is, $X = AX + B$, or $(I - A)X = B$. If $I - A$ is invertible, there's just one fixpoint X. Otherwise, reduce the system to an equivalent one for which you can identify the solutions readily. There are four cases. You might

- derive an *inconsistent* equation equivalent to $0 = 1$ —there's *no* fixpoint;
- reduce the system to three *trivial* equations, each equivalent to $0 = 0$ —*every* point is fixed;

- reduce it to two trivial equations and a nontrivial one that identifies a *plane* of fixpoints, with equation $c_1x_1 + c_2x_2 + c_3x_3 = d$;
- reduce it to one trivial equation and two equations

  $$\begin{cases} x_i - c_i x_k = d_i \\ x_j - c_j x_k = d_j \,, \end{cases}$$

  where $\{i, j, k\} = \{1, 2, 3\}$ —you can convert those to parametric equations for a *line* of fixpoints:

  $$\begin{cases} x_i = t\,c_i + d_i \\ x_j = t\,c_j + d_j \\ x_k = t \cdot 1 + 0 \,. \end{cases}$$

To find fixed lines g of an isometry φ, note that φ maps points $tP + Q$ with $P \neq O$ to points

$$A(tP + Q) + B = tP^* + Q',$$

where $P^* = AP$ and $Q' = AQ + B$. Thus φ maps the line $g \parallel \vec{OP}$ through Q onto a line $g' \parallel \vec{OP}^*$ through Q'. It follows that $g \parallel g'$ just in case P^* is a scalar multiple of P. But φ preserves length, so $g \parallel g'$ just in case $P^* = \pm P$. The first step in finding fixed lines is to find all vectors P such that $P^* = \pm P$. Solve the linear systems $AP = \pm P$ —that is, $(A \pm I)P = O$. Second, find the points Q for which $g = g'$. For each P, both Q and Q' must lie on g, so

$$Q' - Q = AQ + B - Q = (A - I)Q + B = tP$$

for some t. You must solve the system

$$(I - A)Q + tP = B$$

of three linear equations in four unknowns: t and the components of Q.

That general procedure for finding fixed lines may be more involved than what you really need. For these classification exercises, your main fixed-line problem is probably to find the axis g of a screw $\varphi : X \to X' = AX + B$ that has no fixpoint. Here's a neater alternative for that special situation. Since φ affects points X on g like a translation with vector V,

$$\begin{aligned} &X' - X = V = (X')' - X', \\ &AX + B - X = [A(AX + B) + B] - [AX + B] \\ &(A^2 - 2A + I)X = (I - A)B \\ &(I - A)^2 X = (I - A)B. \end{aligned}$$

You can find the points X on g by solving that singular linear system!

You can recognize a similarity $X \to AX + B$ with ratio r by computing $AA^t = r^2 I$; then classify the corresponding isometry $X \to r^{-1}AX + r^{-1}B$.

These exercises are stated in terms of exact fractions. To get *exact* solutions, you'll need mathematical software that operates with exact fractions.[7] You *won't* be able to carry out the computations by hand or by calculator with decimal arithmetic.

You *could* convert each fraction in an exercise to a decimal approximation, and use decimal arithmetic. Do some exercises that way, too! Carry as many decimal digits as your calculator permits. You'll have to make certain decisions in the classification procedure by testing whether some computed number $d = 0$. With approximate decimal arithmetic, you'll never get $d = 0$ *exactly*. So you'll have to decide how close to zero is close enough. In practice, that can be a critical decision. It's important enough in some areas of computer graphics that it's worth covering in more detail *there*. But *these* exercises provide exact fractions so you can clearly relate theory to computation without worrying about approximation errors that depend on your equipment.

Exercise 24. For these matrices A verify that the equation $X' = AX$ defines an isometry or similarity $\varphi : X \to X'$, and classify it.

(a) $\begin{bmatrix} \frac{6}{7} & -\frac{2}{7} & -\frac{3}{7} \\ -\frac{2}{7} & \frac{3}{7} & -\frac{6}{7} \\ -\frac{3}{7} & -\frac{6}{7} & -\frac{2}{7} \end{bmatrix}$ (b) $\begin{bmatrix} \frac{12}{49} & \frac{31}{49} & -\frac{36}{49} \\ \frac{24}{49} & -\frac{36}{49} & -\frac{23}{49} \\ -\frac{41}{49} & -\frac{12}{49} & -\frac{24}{49} \end{bmatrix}$

(c) $\begin{bmatrix} -\frac{9518}{9555} & \frac{131}{1911} & \frac{526}{9555} \\ -\frac{142}{1911} & -\frac{1894}{1911} & -\frac{211}{1911} \\ -\frac{449}{9555} & \frac{218}{1911} & -\frac{9482}{9555} \end{bmatrix}$ (d) $\begin{bmatrix} -6 & 2 & 3 \\ 2 & -3 & 6 \\ 3 & 6 & 2 \end{bmatrix}$.

Exercise 25. For these matrices A and vectors B verify that the equation $X' = AX + B$ defines an isometry or similarity $\varphi : X \to X'$, and classify it.

(a) Same A as exercise 24(a), $B = <{}^4/_7, {}^8/_7, {}^{12}/_7>$;

(b) Same A as exercise 24(a), $B = <5, 6, 7>$;

(c) Same A as exercise 24(b), $B = <{}^4/_7, {}^8/_7, {}^{12}/_7>$;

(d) Same A as exercise 24(c), $B = <{}^{968}/_{195}, {}^{88}/_{39}, -{}^{616}/_{195}>$;

(e) $A = \begin{bmatrix} -\frac{9518}{9555} & -\frac{131}{1911} & \frac{526}{9555} \\ -\frac{142}{1911} & \frac{1894}{1911} & -\frac{211}{1911} \\ -\frac{449}{9555} & -\frac{218}{1911} & -\frac{9482}{9555} \end{bmatrix}$ $B = <{}^{968}/_{195}, {}^{88}/_{39}, -{}^{616}/_{195}>$;

---

[7] *X*(*Plore*) (Meredith 1993) is a good choice.

$$\text{(f) } A = \begin{bmatrix} -9518 & -655 & 526 \\ -710 & 9470 & -1055 \\ -449 & -1090 & -9482 \end{bmatrix} \qquad B = \langle 968, 440, -616 \rangle .$$

Reflection calculus

Just as in two dimensions, geometers have developed approaches to three-dimensional geometry that rely very heavily on algebraic computations with compositions of self-inverse isometries—plane and point reflections and half turns. Because of the greater variety, these approaches are not so elegant as their plane counterparts. The *three-reflections theorems* provide basic tools in both two and three dimensions. The two-dimensional results are theorems 6.4.7, 6.5.6, and 6.7.2, and exercise 6.11.32. Their analogs haven't appeared yet in this more streamlined chapter. They're presented as exercises 26, 27, and 29. The intervening exercise 28 is an extension of lemma 7.5.2 that you'll need for exercise 29.

Exercise 26. Show that for any points P, Q, and R, the composition $\sigma_P \sigma_Q \sigma_R$ is the reflection across point $S = P - Q + R$, and $PQRS$ is a (possibly degenerate) parallelogram.

Exercise 27. Show that the composition φ of the reflections across three planes is self-inverse in just three cases:

(a) they're all perpendicular to a single line g, or
(b) their intersection contains a line g, or
(c) they're mutually perpendicular.

Also show that in case

(a) φ is the reflection across a plane perpendicular to g, and
(b) φ is the reflection across a plane through g, and
(c) φ is the reflection across the intersection of the three planes.

Exercise 28. According to lemma 7.5.2, for any lines b and c the composition $\sigma_b \sigma_c$ is a screw. Fill in the blanks and prove this extension of the lemma:

- $\sigma_b \sigma_c = \iota$ if and only if … ;
- it's a translation if and only if … ;
- it's a rotation if and only if … ;
- if it's not a translation, then its axis is the line that's perpendicular to b and c, and its angle parameter is … ;
- if it's not a rotation, then its vector is … .

Exercise 29. Show that the composition φ of the half turns about three lines is self-inverse in just three cases:

(a) the lines are mutually perpendicular, or
(b) some pair of them is parallel, or
(c) they have a common perpendicular line m.

Show also that in case

(a) $\varphi = \iota$,
(b) φ is the half turn about a line l,
(c) φ is the half turn about a line $l \perp m$.

Exercise 30 is the three-dimensional analog of exercise 6.11.9.

Exercise 30. Show that every isometry φ is the composition of two self-inverse isometries. *Suggestion*: Consider separately the various types of isometry.

Working in the 1920s and early 1930s on the two-dimensional reflection calculus—see that heading in section 6.11—Gerhard Thomsen evidently considered analogous three-dimensional questions. Thomsen's Ph.D. student H. Boldt developed that material into a full theory, published as his dissertation in 1934. It isn't as clean as its two-dimensional counterpart. That's understandable; three-dimensional theorems are generally more complicated. As you've seen in previous exercises on commuting reflections and on the three-reflections theorems, enlarging the class of nontrivial self-inverse isometries from two types to three brings minor complications to almost every elementary theorem. Consequently, even only slightly less elementary results become unwieldy when stated solely in terms of reflections and half turns. Exercises 31 and 32 are taken from Boldt 1934. They're closely related to the two-dimensional reflection calculus exercises in section 6.11.

Exercise 31. Describe the figure formed by points A, B, C, and G for which $\sigma_A\sigma_G\sigma_B\sigma_G\sigma_C\sigma_G = \iota$. Find an analogous result with points A, B, C, D, and G. *Suggestion*: Reason with vectors.

Exercise 32, Part 1. Under what conditions on lines g and h is $\sigma_g\sigma_h\sigma_g\sigma_h = \iota$?

Part 2. Under what conditions on a line g and points P and Q is $\sigma_g\sigma_P\sigma_Q\sigma_g\sigma_Q\sigma_P = \iota$?

Part 3. Under what conditions on a line g and points P and Q is $\sigma_g\sigma_P\sigma_Q\sigma_g\sigma_P\sigma_Q = \iota$?

Part 4. Under what conditions on lines g and h do there exist points P and Q such that $\sigma_g \sigma_h = \sigma_P \sigma_Q$?

Part 5. Under what conditions on lines g and h do there exist points P and Q such that $\sigma_g \sigma_h \sigma_g \sigma_h = \sigma_P \sigma_Q$?

Suggestion: Exercise 28 is helpful.

3.2.6 Convex Functions

A function is called convex if any segment with endpoints on its graph lies above the graph itself. The picture you should have in mind is Figure 21. Formally, if D is an interval of the real axis, or more generally a convex subset of a vector space, then a function $f : D \to \mathbb{R}$ is called convex if

$$f(\lambda x + (1 - \lambda)y) \leq \lambda f(x) + (1 - \lambda) f(y), \quad \text{for all } x, y \in D, \quad \lambda \in (0, 1).$$

Here we should remember that a set D is called convex if for any $x, y \in D$ and $\lambda \in (0, 1)$ the point $\lambda x + (1 - \lambda)y$ is also in D, which geometrically means that D is an intersection of half-spaces.

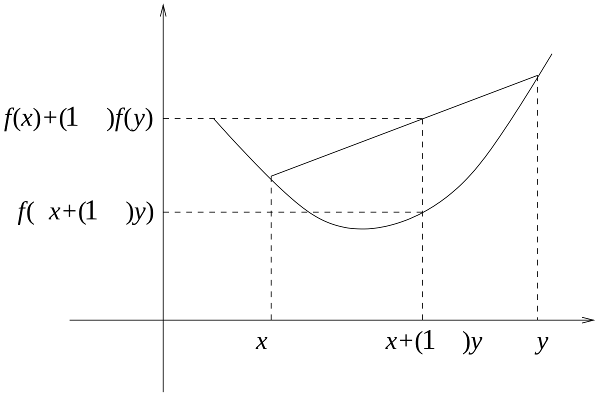

Figure 21

A function f is called concave if $-f$ is convex. If f is both convex and concave, then f is linear, i.e., $f(x) = ax + b$ for some constants a and b.

Proposition. *A twice-differentiable function on an interval is convex if and only if its second derivative is nonnegative.*

In general, a twice-differentiable function defined on a convex domain in $\mathbb{R}^n$ is convex if at any point its Hessian matrix is semipositive definite. This is a way of saying that modulo a local change of coordinates, around each point the function f is of the form

$$f(x_1, x_2, \ldots, x_n) = \phi(x_1, x_2, \ldots, x_n) + x_1^2 + x_2^2 + \cdots + x_k^2,$$

where $k \leq n$ and $\phi(x_1, x_2, \ldots, x_n)$ is linear.

As an application, we use convexity to prove Hölder's inequality.

Hölder's inequality. *If* $x_1, x_2, \ldots, x_n, y_1, y_2, \ldots, y_n, p$, *and* q *are positive numbers with* $\frac{1}{p} + \frac{1}{q} = 1$, *then*

$$\sum_{i=1}^{n} x_i y_i \le \left(\sum_{i=1}^{n} x_i^p\right)^{1/p} \left(\sum_{i=1}^{n} y_i^q\right)^{1/q},$$

with equality if and only if the two vectors $(x_1, x_2, \ldots, x_n)$ *and* $(y_1, y_2, \ldots, y_n)$ *are parallel.*

Proof. The second derivative of $f : (0, \infty) \to \mathbb{R}$, $f(x) = \ln x$, is $f''(x) = -\frac{1}{x^2}$, which is negative. So this function is concave. Setting $\lambda = \frac{1}{p}$, we obtain

$$\ln X^{1/p}Y^{1/q} = \frac{1}{p}\ln X + \frac{1}{q}\ln Y \le \ln\left(\frac{1}{p}X + \frac{1}{q}Y\right), \quad \text{for all } X, Y > 0;$$

hence

$$X^{1/p}Y^{1/q} \le \frac{1}{p}X + \frac{1}{q}Y.$$

Using this fact, if we let $X = \sum_i x_i^p$ and $Y = \sum_i y_i^q$, then

$$\frac{1}{X^{1/p}Y^{1/q}} \sum_{i=1}^{n} x_i y_i = \sum_{i=1}^{n} \left(\frac{x_i^p}{X}\right)^{1/p} \left(\frac{y_i^q}{Y}\right)^{1/q} \le \sum_{i=1}^{n} \left(\frac{1}{p} \cdot \frac{x_i^p}{X} + \frac{1}{q} \cdot \frac{y_i^q}{Y}\right)$$
$$= \left(\frac{1}{p} + \frac{1}{q}\right) = 1.$$

Hence

$$\sum_{i=1}^{n} x_i y_i \le X^{1/p}Y^{1/q} = \left(\sum_{i=1}^{n} x_i^p\right)^{1/p} \left(\sum_{i=1}^{n} y_i^q\right)^{1/q},$$

and the inequality is proved.

By analogy, a sequence $(a_n)_{n \ge 0}$ is called convex if

$$a_n \le \frac{a_{n+1} + a_{n-1}}{2}, \quad \text{for all } n \ge 1,$$

and concave if $(-a_n)_n$ is convex. Equivalently, a sequence is convex if its second difference (derivative) is nonnegative, and concave if its second difference is nonpositive. The following example motivates why convex sequences and functions should be studied together.

Example. Let $(a_n)_n$ be a bounded convex sequence. Prove that

$$\lim_{n \to \infty} (a_{n+1} - a_n) = 0.$$

Solution. A bounded convex function on $(0, \infty)$ has a horizontal asymptote, so its derivative tends to zero at infinity. Our problem is the discrete version of this result. The first derivative of the sequence is $b_n = a_{n+1} - a_n$, $n \ge 1$. The convexity condition can be written as $a_{n+1} - a_n \ge a_n - a_{n-1}$, which shows that $(b_n)_n$ is increasing. Since $(a_n)_n$ is bounded, $(b_n)_n$ is bounded too, and being monotonic, by the Weierstrass theorem it converges at a finite limit L. If $L > 0$, then b_n eventually becomes positive, so a_n becomes increasing because it has a positive derivative. Again by the Weierstrass theorem, a_n converges to some limit l, and then $L = l - l = 0$, a contradiction. A similar argument rules out the case $L < 0$. We are left with the only possibility $L = 0$.

And now some problems.

425. Let $x_1, x_2, \ldots, x_n$ be real numbers. Find the real numbers a that minimize the expression

$$|a - x_1| + |a - x_2| + \cdots + |a - x_n|.$$

426. Let $a, b > 0$ and $x, c > 1$. Prove that

$$x^{a^c} + x^{b^c} \ge 2x^{(ab)^{c/2}}.$$

427. A triangle has side lengths $a \ge b \ge c$ and vertices of measures A, B, and C, respectively. Prove that

$$Ab + Bc + Ca \ge Ac + Ba + Cb.$$

428. Show that if a function $f : [a, b] \to \mathbb{R}$ is convex, then it is continuous on (a, b).

429. Prove that a continuous function defined on a convex domain (for example, on an interval of the real axis) is convex if and only if

$$f\left(\frac{x+y}{2}\right) \le \frac{f(x) + f(y)}{2}, \quad \text{for all } x, y \in D.$$

430. Call a real-valued function *very convex* if

$$\frac{f(x) + f(y)}{2} \ge f\left(\frac{x+y}{2}\right) + |x - y|$$

holds for all real numbers x and y. Prove that no very convex function exists.

431. Let $f : [a, b] \to \mathbb{R}$ be a convex function. Prove that

$$f(x) + f(y) + f(z) + 3f\left(\frac{x+y+z}{3}\right) \ge 2\left[f\left(\frac{x+y}{2}\right) + f\left(\frac{y+z}{2}\right) + f\left(\frac{z+x}{2}\right)\right],$$

for all $x, y, z \in [a, b]$.

432. Prove that if a sequence of positive real numbers $(b_n)_n$ has the property that $(a^n b_n)_n$ is a convex sequence for all real numbers a, then the sequence $(\ln b_n)_n$ is also convex.

433. Find the largest constant C such that for every $n \geq 3$ and every positive concave sequence $(a_k)_{k=1}^n$,

$$\left(\sum_{k=1}^{n} a_k\right)^2 \geq C(n-1)\sum_{k=1}^{n} a_k^2.$$

A convex function on a closed interval attains its maximum at an endpoint of the interval. We illustrate how this fact can be useful with a problem from *Timişoara Mathematics Gazette*, proposed by V. Cârtoaje and M. Lascu.

Example. Let $a, b, c, d \in [1, 3]$. Prove that

$$(a+b+c+d)^2 \geq 3(a^2+b^2+c^2+d^2).$$

Solution. Divide by 2 and move everything to one side to obtain the equivalent inequality

$$a^2+b^2+c^2+d^2-2ab-2ac-2ad-2bc-2bd-2cd \leq 0.$$

Now we recognize the expression on the left to be a convex function in each variable. So the maximum is attained for some choice of $a, b, c, d = 1$ or 3. If k of these numbers are equal to 3, and $4-k$ are equal to 1, where k could be 1, 2, 3, or 4, then the original inequality becomes

$$(3k+4-k)^2 = 3(9k+4-k).$$

Dividing by 3, we obtain $k^2+4k+4 \geq 6k+3$, or $(k-1)^2 \geq 0$, which is clearly true. The inequality is proved. Equality occurs when one of the numbers a, b, c, d is equal to 3 and the other three are equal to 1.

Here are additional problems of this kind.

434. Let α, β, and γ be three fixed positive numbers and $[a, b]$ a given interval. Find x, y, z in $[a, b]$ for which the expression

$$E(x, y, z) = \alpha(x-y)^2 + \beta(y-z)^2 + \gamma(z-x)^2$$

has maximal value.

435. Let $0 < a < b$ and $t_i \geq 0$, $i = 1, 2, \ldots, n$. Prove that for any $x_1, x_2, \ldots, x_n \in [a, b]$,

$$\left(\sum_{i=1}^{n} t_i x_i\right)\left(\sum_{i=1}^{n} \frac{t_i}{x_i}\right) \leq \frac{(a+b)^2}{4ab}\left(\sum_{i=1}^{n} t_i\right)^2.$$

436. Prove that for any natural number $n \geq 2$ and any $|x| \leq 1$,

$$(1+x)^n + (1-x)^n \leq 2^n.$$

437. Prove that for any positive real numbers a, b, c the following inequality holds

$$\frac{a+b+c}{3} - \sqrt[3]{abc} \leq \max\{(\sqrt{a}-\sqrt{b})^2, (\sqrt{b}-\sqrt{c})^2, (\sqrt{c}-\sqrt{a})^2\}.$$

438. Let f be a real-valued continuous function on $\mathbb{R}$ satisfying

$$f(x) \leq \frac{1}{2h}\int_{x-h}^{x+h} f(y)dy, \quad \text{for all } x \in \mathbb{R} \text{ and } h > 0.$$

Prove that (a) the maximum of f on any closed interval is assumed at one of the endpoints, and (b) the function f is convex.

An important property of convex (respectively, concave) functions is known as Jensen's inequality.

Jensen's inequality. *For a convex function f let $x_1, x_2, \ldots, x_n$ be points in its domain and let $\lambda_1, \lambda_2, \ldots, \lambda_n$ be positive numbers with $\lambda_1 + \lambda_2 + \cdots + \lambda_n = 1$. Then*

$$f(\lambda_1 x_1 + \lambda_2 x_2 + \cdots + \lambda_n x_n) \leq \lambda_1 f(x_1) + \lambda_2 f(x_2) + \cdots + \lambda_n f(x_n).$$

If f is nowhere linear and the x_i's are not all equal, then the inequality is strict. The inequality is reversed for a concave function.

Proof. The proof is by induction on n. The base case is the definition of convexity. Let us assume that the inequality is true for any $n-1$ points x_i and any $n-1$ weights λ_i. Consider n points and weights, and let $\lambda = \lambda_1 + \cdots + \lambda_{n-1}$. Note that $\lambda + \lambda_n = 1$ and $\frac{\lambda_1}{\lambda} + \frac{\lambda_2}{\lambda} + \cdots + \frac{\lambda_{n-1}}{\lambda} = 1$. Using the base case and the inductive hypothesis we can write

$$\begin{aligned}
f(\lambda_1 x_1 + \cdots + \lambda_{n-1}x_{n-1} + \lambda_n x_n) &= f\left(\lambda\left(\frac{\lambda_1}{\lambda}x_1 + \cdots + \frac{\lambda_{n-1}}{\lambda}x_{n-1}\right) + \lambda_n x_n\right) \\
&\leq \lambda f\left(\frac{\lambda_1}{\lambda}x_1 + \cdots + \frac{\lambda_{n-1}}{\lambda}x_{n-1}\right) + \lambda_n f(x_n) \\
&\leq \lambda\left(\frac{\lambda_1}{\lambda}f(x_1) + \cdots + \frac{\lambda_{n-1}}{\lambda}f(x_{n-1})\right) + \lambda_n f(x_n) \\
&= \lambda_1 f(x_1) + \cdots + \lambda_{n-1}f(x_{n-1}) + \lambda_n f(x_n),
\end{aligned}$$

as desired. For the case of concave functions, reverse the inequalities.

As an application, we prove the following.

The generalized mean inequality. *Given the positive numbers* $x_1, x_2, \ldots, x_n$ *and the positive weights* $_1, \ _2, \ldots, \ _n$ *with* $_1 + \ _2 + \cdots + \ _n = 1$*, the following inequality holds:*

$$_1x_1 + \ _2x_2 + \cdots + \ _nx_n \quad x_1^{\ 1}x_2^{\ 2}\cdots x_n^{\ n}.$$

Solution. Simply write Jensen s inequality for the concave function $f(x) = \ln x$, then exponentiate.

For $_1 = \ _2 = \cdots = \ _n = \frac{1}{n}$ one obtains the AM GM inequality.

439. Show that if A, B, C are the angles of a triangle, then

$$\sin A + \sin B + \sin C \quad \frac{3\ \overline{3}}{2}.$$

440. Let a_i, $i = 1, 2, \ldots, n$, be nonnegative numbers with $\ {}_{i=1}^{n} a_i = 1$, and let $0 < x_i \quad 1$, $i = 1, 2, \ldots, n$. Prove that

$$\ {}_{i=1}^{n} \frac{a_i}{1 + x_i} \quad \frac{1}{1 + x_1^{a_1}x_2^{a_2}\cdots x_n^{a_n}}.$$

441. Prove that for any three positive real numbers a_1, a_2, a_3,

$$\frac{a_1^2 + a_2^2 + a_3^2}{a_1^3 + a_2^3 + a_3^3} \quad \frac{a_1^3 + a_2^3 + a_3^3}{a_1^4 + a_2^4 + a_3^4}.$$

442. Let $0 < x_i < \ $, $i = 1, 2, \ldots, n$, and set $x = \frac{x_1 + x_2 + \cdots + x_n}{n}$. Prove that

$$\ {}_{i=1}^{n} \frac{\sin x_i}{x_i} \quad \frac{\sin x}{x}^{n}.$$

443. Let $n > 1$ and $x_1, x_2, \ldots, x_n > 0$ be such that $x_1 + x_2 + \cdots + x_n = 1$. Prove that

$$\frac{x_1}{\overline{1 \quad x_1}} + \frac{x_2}{\overline{1 \quad x_2}} + \cdots + \frac{x_n}{\overline{1 \quad x_n}} \quad \frac{\overline{x_1} + \ \overline{x_2} + \cdots + \ \overline{x_n}}{\overline{n \quad 1}}.$$

3.2.7 Indefinite Integrals

Anyone who stops learning is old, whether at twenty or eighty. Anyone who keeps learning stays young. The greatest thing in life is to keep your mind young. Following this advice of Henry Ford, let us teach you some clever tricks for computing indefinite integrals.

518. Prove the Gaussian integral formula

$$\int_{-\infty}^{\infty} e^{-x^2}dx = \sqrt{\pi}.$$

519. Evaluate

$$\int_0^1\int_0^1\int_0^1 (1 + u^2 + v^2 + w^2)^{-2}dudvdw.$$

520. Let $D = \{(x, y) \in \mathbb{R}^2 \mid 0 \leq x \leq y \leq \pi\}$. Prove that

$$\iint_D \ln|\sin(x - y)|dxdy = -\frac{\pi^2}{2}\ln 2.$$

Our next topic is the continuous analogue of the change of the order of summation in a double sum.

Fubini's theorem. *Let* $f : \mathbb{R}^2 \to \mathbb{R}$ *be a piecewise continuous function such that*

$$\int_c^d\int_a^b |f(x, y)|dxdy < \infty.$$

Then

$$\int_c^d\int_a^b f(x, y)dxdy = \int_a^b\int_c^d f(x, y)dydx.$$

The matter of convergence can be bypassed for positive functions, in which case we have the following result.

Tonelli's theorem. *Let* $f : \mathbb{R}^2 \to \mathbb{R}$ *be a positive piecewise continuous function. Then*

$$\int_a^b\int_c^d f(x, y)dxdy = \int_c^d\int_a^b f(x, y)dydx.$$

The limits of integration can be finite or infinite. In the particular case that $f(x, y)$ is constant on the squares of an integer lattice, we recover the discrete version of Fubini's theorem, the change of order of summation in a double sum

$$\sum_{m=0}^{\infty}\sum_{n=0}^{\infty} f(m, n) = \sum_{n=0}^{\infty}\sum_{m=0}^{\infty} f(m, n).$$

A slightly more general situation occurs when f is a step function in one of the variables. In this case we recover the formula for commuting the sum with the integral:

$$\int_a^b \sum_{n=0}^{\infty} f(n,x) = \sum_{n=0}^{\infty} \int_a^b f(n,x).$$

Here we are allowed to commute the sum and the integral if either f is a positive function, or if $\int_a^b \sum_{n=0}^{\infty} |f(n,x)|$ (or equivalently $\sum_{n=0}^{\infty} \int_a^b |f(n,x)|$) is finite. It is now time for an application.

Example. Compute the integral

$$I = \int_0^{\infty} \frac{1}{\sqrt{x}} e^{-x} dx.$$

Solution. We will replace $\frac{1}{\sqrt{x}}$ by a Gaussian integral. Note that for $x > 0$,

$$\int_{-\infty}^{\infty} e^{-xt^2} dt = \int_{-\infty}^{\infty} e^{-(\sqrt{x}t)^2} dt = \frac{1}{\sqrt{x}} \int_{-\infty}^{\infty} e^{-u^2} du = \frac{\sqrt{\pi}}{\sqrt{x}}.$$

Returning to the problem, we are integrating the positive function $\frac{1}{\sqrt{x}} e^{-x}$, which is integrable over the positive semiaxis because in a neighborhood of zero it is bounded from above by $\frac{1}{\sqrt{x}}$ and in a neighborhood of infinity it is bounded from above by $e^{-x/2}$.

Let us consider the two-variable function $f(x,y) = e^{-xt^2} e^{-x}$, which is positive and integrable over $\mathbb{R} \times (0, \infty)$. Using the above considerations and Tonelli's theorem, we can write

$$I = \int_0^{\infty} \frac{1}{\sqrt{x}} e^{-x} dx = \frac{1}{\sqrt{\pi}} \int_0^{\infty} \int_{-\infty}^{\infty} e^{-xt^2} e^{-x} dt dx = \frac{1}{\sqrt{\pi}} \int_{-\infty}^{\infty} \int_0^{\infty} e^{-(t^2+1)x} dx dt$$
$$= \frac{1}{\sqrt{\pi}} \int_{-\infty}^{\infty} \frac{1}{t^2+1} dt = \frac{\pi}{\sqrt{\pi}} = \sqrt{\pi}.$$

Hence the value of the integral in question is $I = \sqrt{\pi}$.

More applications are given below.

521. Let $a_1 \le a_2 \le \cdots \le a_n = m$ be positive integers. Denote by b_k the number of those a_i for which $a_i \ge k$. Prove that

$$a_1 + a_2 + \cdots + a_n = b_1 + b_2 + \cdots + b_m.$$

522. Show that for $s > 0$,

$$\int_0^{\infty} e^{-sx} x^{-1} \sin x dx = \arctan(s^{-1}).$$

523. Show that for $a, b > 0$,

$$\int_0^{\infty} \frac{e^{-ax} - e^{-bx}}{x}dx = \ln \frac{b}{a}.$$

524. Let $|x| < 1$. Prove that

$$\sum_{n=1}^{\infty} \frac{x^n}{n^2} = -\int_0^x \frac{1}{t}\ln(1-t)dt.$$

525. Let $F(x) = \sum_{n=1}^{\infty} \frac{1}{x^2+n^4}$, $x \in \mathbb{R}$. Compute $\int_0^{+\infty} F(t)dt$.

3.3.3 The Many Versions of Stokes' Theorem

We advise you that this is probably the most difficult section of the book. Yet Stokes' theorem plays such an important role in mathematics that it deserves an extensive treatment. As an encouragement, we offer you a quote by Marie Curie: "Nothing in life is to be feared. It is only to be understood."

In its general form, Stokes' theorem is known as

$$\int_M d\omega = \int_{\partial M} \omega,$$

where ω is a k-form, $d\omega$ its differential, and M a domain with boundary ∂M. The one-dimensional case is the most familiar; it is the Leibniz–Newton formula

$$\int_a^b f'(t)dt = f(b) - f(a).$$

Three versions of this result are of interest to us.

Green's theorem. *Let* D *be a domain in the plane with boundary* C *oriented such that* D *is to the left. If the vector field* $\vec{F}(x, y) = P(x, y)\vec{i} + Q(x, y)\vec{j}$ *is continuously differentiable on* D*, then*

$$\oint_C Pdx + Qdy = \iint_D \left(\frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y}\right) dxdy.$$

Stokes' Theorem. *Let* S *be an oriented surface with normal vector* $\vec{n}$*, bounded by a closed, piecewise smooth curve* C *that is oriented such that if one travels on* C *with the upward direction* $\vec{n}$*, the surface is on the left. If* $\vec{F}$ *is a vector field that is continuously differentiable on* S*, then*

$$\oint_C \vec{F} \cdot d\vec{R} = \iint_S (\text{curl}\,\vec{F} \cdot \vec{n})dS,$$

where dS *is the area element on the surface.*

The Gauss Ostrogradsky (Divergence) Theorem. *Let* S *be a smooth, orientable surface that encloses a solid region* V *in space. If* F *is a continuously differentiable vector field on* V*, then*

$$\mathop{}_{S} F \cdot n\, dS = \mathop{}_{V} \operatorname{div} F\, dV,$$

where n *is the outward unit normal vector to the surface* S, dS *is the area element on the surface, and* dV *is the volume element inside of* V.

We recall that for a vector field $F = (F_1, F_2, F_3)$, the divergence is

$$\operatorname{div} F = \quad \cdot F = \frac{F_1}{x} + \frac{F_2}{y} + \frac{F_3}{z},$$

while the curl is

$$\operatorname{curl} F = \quad \times F = \begin{matrix} i & j & k \\ \frac{}{x} & \frac{}{y} & \frac{}{z} \\ F_1 & F_2 & F_3 \end{matrix}$$

$$= \quad \frac{F_3}{y} \quad \frac{F_2}{z} \quad i + \quad \frac{F_1}{z} \quad \frac{F_3}{x} \quad j + \quad \frac{F_2}{x} \quad \frac{F_1}{y} \quad k.$$

The quantity $\overset{++}{}_{S} F \cdot n\, dS$ is called the flux of F across the surface S.

Let us illustrate the use of these theorems with some examples. We start with an encouraging problem whose solution is based on Stokes theorem.

Example. Compute

$$\overset{5}{}_{C}\, y dx + z dy + x dz,$$

where C is the circle $x^2 + y^2 + z^2 = 1$, $x + y + z = 1$, oriented counterclockwise when seen from the positive side of the x-axis.

Solution. By Stokes theorem,

$$\overset{5}{}_{C}\, y dx + z dy + x dz = \mathop{}_{S} \operatorname{curl} F \cdot n\, dS,$$

where S is the disk that the circle bounds. It is straightforward that $\operatorname{curl} F = (\ 1,\ 1,\ 1)$, while n, the normal vector to the plane $x + y + z = 1$, is equal to $(\frac{1}{3}, \frac{1}{3}, \frac{1}{3})$. Therefore,

$$\oint_C y\,dx + z\,dy + x\,dz = -A\sqrt{3},$$

where A is the area of the disk bounded by C. Observe that C is the circumcircle of the triangle with vertices $(1, 0, 0)$, $(0, 1, 0)$, and $(0, 0, 1)$. The circumradius of this triangle is $\frac{\sqrt{6}}{3}$, so $A = \frac{2\pi}{3}$. The answer to the problem is therefore $-\frac{2\pi\sqrt{3}}{3}$.

Example. Orthogonal to each face of a polyhedron construct an outward vector with length numerically equal to the area of the face. Prove that the sum of all these vectors is equal to zero.

Solution. We exhibit first an elementary solution based on vector operations. Consider the particular case of a tetrahedron $ABCD$. The four vectors are $\frac{1}{2}BC \times BA$, $\frac{1}{2}BA \times BD$, $\frac{1}{2}BD \times BC$, and $\frac{1}{2}DA \times DC$. Indeed, the lengths of these vectors are numerically equal to the areas of the corresponding faces, and the cross-product of two vectors is perpendicular to the plane determined by the vectors, and it points outward because of the right-hand rule. We have

$$\begin{aligned}
&BC \times BA + BA \times BD + BD \times BC + DA \times DC\\
&\quad = BC \times BA + BA \times BD + BD \times BC + (BA - BD) \times (BC - BD)\\
&\quad = BC \times BA + BA \times BD + BD \times BC + BA \times BC - BA \times BD\\
&\qquad - BD \times BC + 0 = 0.
\end{aligned}$$

This proves that the four vectors add up to zero.

In the general case, dissect the polyhedron into tetrahedra cutting the faces into triangles by diagonals and then joining the centroid of the polyhedron with the vertices. Sum up all vectors perpendicular to the faces of these tetrahedra, and note that the vectors corresponding to internal walls cancel out.

The elegant solution uses integrals. Let S be the polyhedron and assume that its interior V is filled with gas at a (not necessarily constant) pressure p. The force that the gas exerts on S is $\iint_S p\,n\,dA$, where n is the outward normal vector to the surface of the polyhedron and dA is the area element. The divergence theorem implies that

$$\iint_S p\,n\,dA = \iiint_V \nabla p\,dV.$$

Here ∇p denotes the gradient of p. If the pressure p is constant, then the right-hand side is equal to zero. This is the case with our polyhedron, where $p = 1$. The double integral is exactly the sum of the vectors under discussion, these vectors being the forces exerted by pressure on the faces.

As a corollary, we obtain the well-known fact that a container filled with gas under pressure is at equilibrium; a balloon will never move as a result of internal pressure.

We conclude our series of examples with an application of Green s theorem, the proof given by D. Pompeiu to Cauchy s formula for holomorphic functions. First, let us introduce some notation for functions of a complex variable $f(z) = f(x + iy) = u(x, y) + iv(x, y)$. If u and v are continuously differentiable, define

$$\frac{f}{\bar{z}} = \frac{1}{2} \quad \frac{f}{x} + i\frac{f}{y} \quad = \frac{1}{2} \quad \frac{u}{x} \quad \frac{v}{y} \quad + i \quad \frac{u}{y} + \frac{v}{x} \quad .$$

The function f is called holomorphic if $\frac{f}{\bar{z}} = 0$. Examples are polynomials in z and any absolutely convergent power series in z. Also, let $dz = dx + idy$.

Cauchy s theorem. *Let be an oriented curve that bounds a region on its left, and let* a *. If* $f(z) = f(x + iy) = u(x, y) + iv(x, y)$ *is a holomorphic function on such that* u *and* v *are continuous on and continuously differentiable on , then*

$$f(a) = \frac{1}{2\ \ i} \overset{5}{\ } \quad \frac{f(z)}{z \quad a} dz.$$

Proof. The proof is based on Green s formula, applied on the domain obtained from by removing a disk of radius around a as described in Figure 23 to $P = F$ and $Q = iF$, where F is a holomorphic function to be specified later. Note that the boundary of the domain consists of two curves, and .

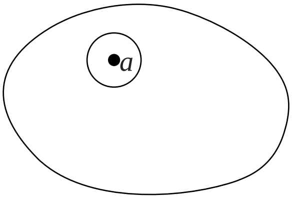

Figure 23

Green s formula reads

$$\overset{5}{\ } \quad F dz \quad \overset{5}{\ } \quad F dz = \overset{5}{\ } \quad F dx + iF dy \quad \overset{5}{\ } \quad F dx + iF dy$$

$$= \quad i \quad \frac{F}{x} + i\frac{F}{y} \quad dxdy = 2i \quad \frac{F}{\bar{z}} dxdy = 0.$$

Therefore,

$$\overset{5}{\ } \quad F(z)dz = \overset{5}{\ } \quad F(z)dz.$$

We apply this to

$$F(z) = \frac{f(z)}{z \quad a} = \frac{(u(x,y) + iv(x,y))(x \quad iy + \qquad i\ )}{(x + \ \ )^2 + (y + \ \ )^2},$$

where $a = \quad + i\ $. It is routine to check that F is holomorphic. We thus have

$$5\ \frac{f(z)}{z \quad a}dz = 5\ \frac{f(z)}{z \quad a}dz.$$

The change of variable $z = a + \ \ e^{it}$ on the right-hand side yields

$$5\ \frac{f(z)}{z \quad a}dz = \frac{f(a + \ \ e^{it})}{e^{it}} i\ \ e^{it}dt = i \qquad f(a + \ \ e^{it})dt.$$

When $\qquad 0$ this tends to $2\ \ if(a)$, and we obtain

$$5\ \frac{f(z)}{z \quad a}dz = 2\ \ if(a).$$

Hence the desired formula.

526. Assume that a curve $(x(t), y(t))$ runs counterclockwise around a region D. Prove that the area of D is given by the formula

$$A = \frac{1}{2}\ 5_{D}\ (xy \quad yx\ )dt.$$

527. Compute the flux of the vector field

$$F(x,y,z) = x(e^{xy} \quad e^{zx})\ i \ + y(e^{yz} \quad e^{xy})\ j \ + z(e^{zx} \quad e^{yz})\ k$$

across the upper hemisphere of the unit sphere.

528. Compute

$$5_{C}\ y^2dx + z^2dy + x^2dz,$$

where C is the Viviani curve, defined as the intersection of the sphere $x^2 + y^2 + z^2 = a^2$ with the cylinder $x^2 + y^2 = ax$.

529. Let $\ (x,y,z)$ and $\ (x,y,z)$ be twice continuously differentiable functions in the region $\{(x,y,z) \mid \frac{1}{2} < \overline{\ \ x^2 + y^2 + z^2} < 2\}$. Prove that

$$_{S}(\qquad \times \qquad)\cdot\ n\, dS = 0,$$

where S is the unit sphere centered at the origin, n is the normal unit vector to this sphere, and $\qquad$ denotes the gradient $\frac{\ }{x}\mathbf{i} + \frac{\ }{y}\mathbf{j} + \frac{\ }{z}\mathbf{k}$.

530. Let $f, g : \mathbb{R}^3 \to \mathbb{R}$ be twice continuously differentiable functions that are constant along the lines that pass through the origin. Prove that on the unit ball $B = \{(x, y, z) \mid x^2 + y^2 + z^2 \leq 1\}$,

$$\iiint_B f \nabla^2 g \, dV = \iiint_B g \nabla^2 f \, dV.$$

Here $\nabla^2 = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2}$ is the Laplacian.

531. Prove Gauss' law, which states that the total flux of the gravitational field through a closed surface equals $-4\pi G$ times the mass enclosed by the surface, where G is the constant of gravitation. The mathematical formulation of the law is

$$\iint_S \mathbf{F} \cdot \mathbf{n} \, dS = -4\pi MG.$$

532. Let

$$G(x, y) = \left(-\frac{y}{x^2 + 4y^2}, \frac{x}{x^2 + 4y^2}, 0 \right).$$

Prove or disprove that there is a vector field $F : \mathbb{R}^3 \to \mathbb{R}^3$,

$$F(x, y, z) = (M(x, y, z), N(x, y, z), P(x, y, z)),$$

with the following properties:

(i) M, N, P have continuous partial derivatives for all $(x, y, z) \neq (0, 0, 0)$;
(ii) curl $F = \mathbf{0}$, for all $(x, y, z) \neq (0, 0, 0)$;
(iii) $F(x, y, 0) = G(x, y)$.

533. Let $\mathbf{F} : \mathbb{R}^2 \to \mathbb{R}^2$, $\mathbf{F}(x, y) = (F_1(x, y), F_2(x, y))$ be a vector field, and let $G : \mathbb{R}^3 \to \mathbb{R}$ be a smooth function whose first two variables are x and y, and the third is t, the time. Assume that for any rectangular surface D bounded by the curve C,

$$\frac{d}{dt} \iint_D G(x, y, t) dx dy = \oint_C \mathbf{F} \cdot d\mathbf{R}.$$

Prove that

$$\frac{\partial G}{\partial t} + \frac{\partial F_2}{\partial x} + \frac{\partial F_1}{\partial y} = 0.$$

534. For two disjoint oriented curves C_1 and C_2 in three-dimensional space, parametrized by $\vec{v}_1(s)$ and $\vec{v}_2(t)$, define the linking number

$$\mathrm{lk}(C_1, C_2) = \frac{1}{4\pi} \oint_{C_1} \oint_{C_2} \frac{\vec{v}_1 - \vec{v}_2}{\|\vec{v}_1 - \vec{v}_2\|^3} \cdot \left(\frac{d\vec{v}_1}{ds} \times \frac{d\vec{v}_2}{dt} \right) dt\,ds.$$

Prove that if the oriented curves C_1 and $-C_1'$ bound an oriented surface S such that S is to the left of each curve, and if the curve C_2 is disjoint from S, then $\mathrm{lk}(C_1, C_2) = \mathrm{lk}(C_1', C_2)$.

3.4 Equations with Functions as Unknowns

3.4.1 Functional Equations

We will now look at equations whose unknowns are functions. Here is a standard example that we found in B.J. Venkatachala, *Functional Equations: A Problem Solving Approach* (Prism Books PVT Ltd., 2002).

Example. Find all functions $f : \mathbb{R} \to \mathbb{R}$ satisfying the functional equation

$$f((x - y)^2) = f(x)^2 - 2xf(y) + y^2.$$

Solution. For $y = 0$, we obtain

$$f(x^2) = f(x)^2 - 2xf(0),$$

and for $x = 0$, we obtain

$$f(y^2) = f(0)^2 + y^2.$$

Setting $y = 0$ in the second equation, we find that $f(0) = 0$ or $f(0) = 1$. On the other hand, combining the two equalities, we obtain

$$f(x)^2 - 2xf(0) = f(0)^2 + x^2,$$

that is,

$$f(x)^2 = (x + f(0))^2.$$

Substituting this in the original equation yields

$$\begin{aligned} f(y) &= \frac{f(x)^2 - f((x - y)^2) + y^2}{2x} = \frac{(x + f(0))^2 - (x - y + f(0))^2 + y^2}{2x} \\ &= y + f(0). \end{aligned}$$

We conclude that the functional equation has the two solutions $f(x) = x$ and $f(x) = x + 1$.

(Gh. Bucur, E. Câmpu, S. Gaina, *Culegere de Probleme de Calcul Diferenţial şi Integral* (*Collection of Problems in Differential and Integral Calculus*), Editura Tehnica, Bucharest, 1967)

518. The method is similar to that for computing the Fresnel integrals, only simpler. If we denote the integral by I, then

$$I^2 = \quad e^{\ x^2}dx \quad e^{\ y^2}dy = \quad e^{\ (x^2+y^2)}dxdy.$$

Switching to polar coordinates, we obtain

$$I^2 = {}^{\ 2}_{0}\ {}_{0}\ e^{\ r^2}rdrd \ = {}^{\ 2}_{0}\ \frac{1}{2}\ e^{\ r^2}\ {}_{0}\ d \ = {}^{\ 2}_{0}\ \frac{1}{2}d \ = \ .$$

Hence the desired formula $I = \ \overline{}$.

519. Call the integral I. By symmetry, we may compute it over the domain $\{(u,v,w) \quad R^3 \mid 0 \quad v \quad u \quad 1\}$, then double the result. We substitute $u = r\cos \ $, $v = r\sin \ $, $w = \tan \ $, taking into account that the limits of integration become 0 , $\frac{}{4}$, and 0 r sec . We have

$$\begin{aligned} I &= 2\ {}^{\frac{}{4}}_{0}\ {}^{\frac{}{4}}_{0}\ {}^{\sec}_{0}\ \frac{r\sec^2}{(1 + r^2\cos^2 \ + r^2\sin^2 \ + \tan^2 \ )^2}drd \ d \\ &= 2\ {}^{\frac{}{4}}_{0}\ {}^{\frac{}{4}}_{0}\ {}^{\sec}_{0}\ \frac{r\sec^2}{(r^2 + \sec^2 \ )^2}drd \ d \\ &= 2\ {}^{\frac{}{4}}_{0}\ {}^{\frac{}{4}}_{0}\ \sec^2 \ \ \frac{1}{2(r^2 + \sec^2 \ )}\Bigg|^{r=\sec}_{r=0} d \ d \\ &= \ {}^{\frac{}{4}}_{0}\ {}^{\frac{}{4}}_{0}\ \frac{\sec^2}{\sec^2 \ + \sec^2}d \ d \ + \ \frac{}{4}^{\ 2}. \end{aligned}$$

But notice that this is the same as

$${}^{\frac{}{4}}_{0}\ {}^{\frac{}{4}}_{0}\ 1 \quad \frac{\sec^2}{\sec^2 \ + \sec^2} \ d \ d \ = {}^{\frac{}{4}}_{0}\ {}^{\frac{}{4}}_{0}\ \frac{\sec^2}{\sec^2 \ + \sec^2}d \ d \ .$$

If we exchange the roles of and in this last integral we see that

$${}^{\frac{}{4}}_{0}\ {}^{\frac{}{4}}_{0}\ \frac{\sec^2}{\sec^2 \ + \sec^2}d \ d \ + \ \frac{}{4}^{\ 2} = {}^{\frac{}{4}}_{0}\ {}^{\frac{}{4}}_{0}\ \frac{\sec^2}{\sec^2 \ + \sec^2}d \ d \ .$$

Hence

$${}^{\frac{}{4}}_{0}\ {}^{\frac{}{4}}_{0}\ \frac{\sec^2}{\sec^2 \ + \sec^2}d \ d \ = \frac{\ ^2}{32}.$$

Consequently, the integral we are computing is equal to $\frac{\pi^2}{32}$.

(*American Mathematical Monthly*, proposed by M. Hajja and P. Walker)

520. We have

$$\begin{aligned} I &= \iint_D \ln|\sin(x-y)|\,dx\,dy = \int_0^{\pi}\left(\int_0^{y}\ln|\sin(y-x)|\,dx\right)dy \\ &= \int_0^{\pi}\left(\int_0^{y}\ln\sin t\,dt\right)dy = y\int_0^{y}\ln\sin t\,dt\,\Big|_{y=0}^{y=\pi} - \int_0^{\pi} y\ln\sin y\,dy \\ &= \pi A - B, \end{aligned}$$

where $A = \int_0^{\pi}\ln\sin t\,dt$, $B = \int_0^{\pi} t\ln\sin t\,dt$. Note that here we used integration by parts! We compute further

$$\begin{aligned} A &= \int_0^{\frac{\pi}{2}}\ln\sin t\,dt + \int_{\frac{\pi}{2}}^{\pi}\ln\sin t\,dt = \int_0^{\frac{\pi}{2}}\ln\sin t\,dt + \int_0^{\frac{\pi}{2}}\ln\cos t\,dt \\ &= \int_0^{\frac{\pi}{2}}(\ln\sin 2t - \ln 2)\,dt = -\frac{\pi}{2}\ln 2 + \frac{1}{2}A. \end{aligned}$$

Hence $A = -\pi\ln 2$. For B we use the substitution $t = \pi - x$ to obtain

$$B = \int_0^{\pi}(\pi - x)\ln\sin x\,dx = \pi A - B.$$

Hence $B = \frac{\pi}{2}A$. Therefore, $I = \pi A - B = -\frac{\pi^2}{2}\ln 2$, and we are done.

Remark. The identity

$$\int_0^{\frac{\pi}{2}}\ln\sin t\,dt = -\frac{\pi}{2}\ln 2$$

belongs to Euler.

(S. Radulescu, M. Radulescu, *Teoreme și Probleme de Analiză Matematică* (*Theorems and Problems in Mathematical Analysis*), Editura Didactica și Pedagogica, Bucharest, 1982).

521. This problem applies the discrete version of Fubini's theorem. Define

$$f(i,j) = \begin{cases} 1 & \text{for } j \le a_i, \\ 0 & \text{for } j > a_i. \end{cases}$$

The left-hand side is equal to $\sum_{i=1}^{n}\sum_{j=1}^{m} f(i,j)$, while the right-hand side is equal to $\sum_{j=1}^{m}\sum_{i=1}^{n} f(i,j)$. The equality follows.

522. First, note that for $x > 0$,

$$e^{-sx}x^{-1}|\sin x| < e^{-sx},$$

so the integral that we are computing is finite.

Now consider the two-variable function

$$f(x,y) = e^{-sxy}\sin x.$$

We have

$$\int_0^\infty\int_1^\infty |f(x,y)|dydx = \int_0^\infty\int_1^\infty e^{-sxy}|\sin x|dydx = \frac{1}{s}\int_0^\infty e^{-sx}x^{-1}|\sin x|dx,$$

and we just saw that this is finite. Hence we can apply Fubini's theorem, to conclude that on the one hand,

$$\int_0^\infty\int_1^\infty f(x,y)dydx = \frac{1}{s}\int_0^\infty e^{-sx}x^{-1}\sin x dx,$$

and on the other hand,

$$\int_0^\infty\int_1^\infty f(x,y)dydx = \int_1^\infty \frac{1}{s^2y^2+1}dy.$$

Here of course we used the fact that

$$\int_0^\infty e^{-ax}\sin x dx = \frac{1}{a^2+1}, \quad a > 0,$$

a formula that can be proved by integrating by parts. Equating the two expressions that we obtained for the double integral, we obtain

$$\int_0^\infty e^{-sx}x^{-1}\sin x dx = \frac{\pi}{2} - \arctan s = \arctan(s^{-1}),$$

as desired.

(G.B. Folland, *Real Analysis, Modern Techniques and Their Applications*, Wiley, 1999)

523. Applying Tonelli's theorem to the function $f(x,y) = e^{-xy}$, we can write

$$\begin{aligned}\int_0^\infty \frac{e^{-ax}-e^{-bx}}{x}dx &= \int_0^\infty\int_a^b e^{-xy}dydx = \int_a^b\int_0^\infty e^{-xy}dxdy\\ &= \int_a^b \frac{1}{y}dy = \ln\frac{b}{a}.\end{aligned}$$

Remark. This is a particular case of integrals of the form $\int_0^{+\infty}\frac{f(ax)-f(bx)}{x}dx$, known as Froullani integrals. In general, if f is continuous and has finite limit at infinity, the value of the integral is $(f(0)-\lim_{x\to\infty} f(x))\ln\frac{b}{a}$.

524. We do the proof in the case $0<x<1$, since for $-1<x<0$ the proof is completely analogous, while for $x=0$ the property is obvious. The function $f:\mathbb{N}\times[0,x]\to\mathbb{R}$, $f(n,t)=t^{n-1}$ satisfies the hypothesis of Fubini's theorem. So integration commutes with summation:

$$\sum_{n=0}^{\infty}\int_0^x t^{n-1}dt=\int_0^x\frac{dt}{1-t}.$$

This implies

$$\sum_{n=1}^{\infty}\frac{x^n}{n}=-\ln(1-x).$$

Dividing by x, we obtain

$$\sum_{n=1}^{\infty}\frac{x^{n-1}}{n}=-\frac{1}{x}\ln(1-x).$$

The right-hand side extends continuously at 0, since $\lim_{x\to 0}\frac{1}{t}\ln(1-t)=-1$. Again we can apply Fubini's theorem to $f(n,t)=\frac{t^{n-1}}{n}$ on $\mathbb{N}\times[0,x]$ to obtain

$$\sum_{n=1}^{\infty}\frac{x^n}{n^2}=\sum_{n=1}^{\infty}\int_0^x\frac{t^{n-1}}{n}dt=\int_0^x\sum_{n=1}^{\infty}\frac{t^{n-1}}{n}dt=\int_0^x-\frac{1}{t}\ln(1-t)dt,$$

as desired.

525. We can apply Tonelli's theorem to the function $f(x,n)=\frac{1}{x^2+n^4}$. Integrating term by term, we obtain

$$\int_0^x F(t)dt=\int_0^x\sum_{n=1}^{\infty}f(t,n)dt=\sum_{n=1}^{\infty}\int_0^x\frac{dt}{t^2+n^4}=\sum_{n=1}^{\infty}\frac{1}{n^2}\arctan\frac{x}{n^2}.$$

This series is bounded from above by $\sum_{n=1}^{\infty}\frac{1}{n^2}=\frac{\pi^2}{6}$. Hence the summation commutes with the limit as x tends to infinity. We have

$$\int_0^{\infty}F(t)dt=\lim_{x\to\infty}\int_0^x F(t)dt=\lim_{x\to\infty}\sum_{n=1}^{\infty}\frac{1}{n^2}\arctan\frac{x}{n^2}=\sum_{n=1}^{\infty}\frac{1}{n^2}\cdot\frac{\pi}{2}.$$

Using the identity $_{n \quad 1}\frac{1}{n^2} = \frac{\ ^2}{6}$, we obtain

$$_{0}\ F(t)dt = \frac{\ ^3}{12}.$$

(Gh. Sireţchi, *Calcul Diferenţial şi Integral* (*Differential and Integral Calculus*), Editura Ştiinţifica şi Enciclopedica, Bucharest, 1985)

526. The integral from the statement can be written as

$$^{5}_{D}\ xdy \quad ydx.$$

Applying Green s theorem for $P(x,y) = \quad y$ and $Q(x,y) = x$, we obtain

$$^{5}_{D}\ xdy \quad ydx = \quad _{D}(1+1)dxdy,$$

which is twice the area of D. The conclusion follows.

527. It can be checked that div $F = 0$ (in fact, F is the curl of the vector field $e^{yz}\ i + e^{zx}\ j + e^{xy}\ k$). If S be the union of the upper hemisphere and the unit disk in the xy-plane, then by the divergence theorem $\overset{++}{}_{S}\ F \bullet n\, dS = 0$. And on the unit disk $F \bullet n = 0$, which means that the flux across the unit disk is zero. It follows that the flux across the upper hemisphere is zero as well.

528. We simplify the computation using Stokes theorem:

$$^{5}_{C}\ y^2dx + z^2dy + x^2dz = \quad 2 \quad _{S}\ ydxdy + zdydz + xdzdx,$$

where S is the portion of the sphere bounded by the Viviani curve. We have

$$2 \quad _{S}\ ydxdy + zdydz + xdzdx = \quad 2 \quad _{S}(z,x,y) \bullet n\, d \quad ,$$

where (z,x,y) denotes the three-dimensional vector with coordinates z, x, and y, while n denotes the unit vector normal to the sphere at the point of coordinates (x,y,z). We parametrize the portion of the sphere in question by the coordinates (x,y), which range inside the circle $x^2 + y^2 \quad ax = 0$. This circle is the projection of the Viviani curve onto the xy-plane.

The unit vector normal to the sphere is

$$n = \frac{x}{a}, \frac{y}{a}, \frac{z}{a} = \frac{x}{a}, \frac{y}{a}, \frac{\overline{a^2 \quad x^2 \quad y^2}}{a} \quad ,$$

while the area element is

$$d\ \ = \frac{1}{\cos\ }dxdy,$$

being the angle formed by the normal to the sphere with the xy-plane. It is easy to see that $\cos\ \ = \frac{z}{a} = \frac{\overline{a^2\ \ x^2\ \ y^2}}{a}$. Hence the integral is equal to

$$2\ \ _D\ z\frac{x}{a} + x\frac{y}{a} + y\frac{z}{a}\ \ \frac{a}{z}dxdy = \ 2\ \ _D\ x + y + \frac{xy}{\overline{a^2\ \ x^2\ \ y^2}}\ \ dxdy,$$

the domain of integration D being the disk $x^2 + y^2\ \ \ ax\ \ \ 0$. Split the integral as

$$2\ \ _D(x + y)dxdy\ \ \ 2\ \ _D\frac{xy}{\overline{a^2\ \ x^2\ \ y^2}}dxdy.$$

Because the domain of integration is symmetric with respect to the y-axis, the second double integral is zero. The first double integral can be computed using polar coordinates: $x = \frac{a}{2} + r\cos\ $, $y = r\sin\ $, $0\ \ \ r\ \ \ \frac{a}{2}$, $0\ \ \ \ \ 2\ $. Its value is $\ \frac{a^3}{4}$, which is the answer to the problem.

(D. Flondor, N. Donciu, *Algebră și Analiză Matematică* (*Algebra and Mathematical Analysis*), Editura Didactica și Pedagogica, Bucharest, 1965)

529. We will apply Stokes' theorem. We begin with

$$\frac{}{y}\frac{}{z}\ \ \ \ \frac{}{z}\frac{}{y} = \frac{}{y}\frac{}{z} + \frac{^2}{y\ z}\ \ \ \ \frac{}{z}\frac{}{y}\ \ \ \ \frac{^2}{z\ y}$$

$$= \frac{}{y}\ \ \ \frac{}{z}\ \ \ \ \frac{}{z}\ \ \ \frac{}{y}\ \ ,$$

which combined with the two other analogous computations gives

$$\times\ \ \ = \mathrm{curl}(\ \ \ ).$$

By Stokes' theorem, the integral of the curl of a vector field on a surface without boundary is zero.

(Soviet University Student Mathematical Competition, 1976)

530. For the solution, recall the following identity.

Green's first identity. *If* f *and* g *are twice-differentiable functions on the solid region* R *bounded by the closed surface* S*, then*

$$_R(f\ \ ^2g + \ \ f\bullet\ \ g)dV = \ \ _S\ f\frac{g}{n}dS,$$

where $\frac{g}{n}$ *is the derivative of* g *in the direction of the normal to the surface.*

Proof. For the sake of completeness we will prove Green's identity. Consider the vector field $F = f\nabla g$. Then

$$\begin{aligned}\operatorname{div} F &= \frac{\partial}{\partial x}\left(f\frac{\partial g}{\partial x}\right) + \frac{\partial}{\partial y}\left(f\frac{\partial g}{\partial y}\right) + \frac{\partial}{\partial z}\left(f\frac{\partial g}{\partial z}\right)\\ &= f\left(\frac{\partial^2 g}{\partial x^2} + \frac{\partial^2 g}{\partial y^2} + \frac{\partial^2 g}{\partial z^2}\right) + \left(\frac{\partial f}{\partial x}\frac{\partial g}{\partial x} + \frac{\partial f}{\partial y}\frac{\partial g}{\partial y} + \frac{\partial f}{\partial z}\frac{\partial g}{\partial z}\right).\end{aligned}$$

So the left-hand side is $\iiint_R \operatorname{div} F\, dV$. By the Gauss–Ostrogradski divergence theorem this is equal to

$$\iint_S (f\nabla g)\cdot n\, dS = \iint_S f(\nabla g \cdot n)dS = \iint_S f\frac{\partial g}{\partial n}dS.$$

Writing Green's first identity for the vector field $g\nabla f$ and then subtracting it from that of the vector field $f\nabla g$, we obtain Green's second identity

$$\iiint_R (f\nabla^2 g - g\nabla^2 f)dV = \iint_S \left(f\frac{\partial g}{\partial n} - g\frac{\partial f}{\partial n}\right)dS.$$

The fact that f and g are constant along the lines passing through the origin means that on the unit sphere, $\frac{\partial f}{\partial n} = \frac{\partial g}{\partial n} = 0$. Hence the conclusion.

531. Because F is obtained as an integral of the point-mass contributions of the masses distributed in space, it suffices to prove this equality for a mass M concentrated at one point, say the origin.

Newton's law says that the gravitational force between two masses m_1 and m_2 at distance r is equal to $\frac{m_1 m_2 G}{r^2}$. By Newton's law, a mass M located at the origin generates the gravitational field

$$F(x, y, z) = -MG\frac{1}{x^2+y^2+z^2}\cdot\frac{x\,i + y\,j + z\,k}{\sqrt{x^2+y^2+z^2}} = -MG\frac{x\,i + y\,j + z\,k}{(x^2+y^2+z^2)^{3/2}}.$$

One can easily check that the divergence of this field is zero. Consider a small sphere S_0 of radius r centered at the origin, and let V be the solid lying between S_0 and S. By the Gauss–Ostrogradski divergence theorem,

$$\iint_S F\cdot n\, dS - \iint_{S_0} F\cdot n\, dS = \iiint_V \operatorname{div} F\, dV = 0.$$

Hence it suffices to prove the Gauss law for the sphere S_0. On this sphere the flow $F\cdot n$ is constantly equal to $-\frac{GM}{r^2}$. Integrating it over the sphere gives $-4\pi MG$, proving the law.

532. The condition curl $\mathbf{F} = 0$ suggests the use of Stokes' theorem:

$$\iint_S \text{curl}\,\mathbf{F}\cdot\mathbf{n}\,dS = \oint_C \mathbf{F}\cdot d\mathbf{R}.$$

We expect the answer to the question to be no. All we need is to find a surface S whose boundary lies in the xy-plane and such that the integral of $\mathbf{G}(x, y)$ on ∂S is nonzero.

A simple example that comes to mind is the interior S of the ellipse $x^2 + 4y^2 = 4$. Parametrize the ellipse as $x = 2\cos\theta$, $y = \sin\theta$, $\theta \in [0, 2\pi)$. Then

$$\oint_{\partial S} \mathbf{G}\cdot d\mathbf{R} = \int_0^{2\pi}\left(-\frac{\sin\theta}{4}, \frac{2\cos\theta}{4}, 0\right)\cdot(-2\sin\theta, \cos\theta, 0)d\theta = \int_0^{2\pi}\frac{1}{2}d\theta = \pi.$$

By Stokes' theorem this should be equal to the integral of the curl of $\mathbf{F}$ over the interior of the ellipse. The curl of $\mathbf{F}$ is zero except at the origin, but we can fix that by adding a smooth tiny upward bump at the origin, which does not alter too much the above computation. The integral should on the one hand be close to 0, and on the other hand close to π, which is impossible. This proves that such a vector field $\mathbf{F}$ cannot exist.

(48th W.L. Putnam Mathematical Competition, 1987, solution from K. Kedlaya, B. Poonen, R. Vakil, *The William Lowell Putnam Mathematical Competition* 1985–2000, MAA, 2002)

533. Let $D = [a_1, b_1] \times [a_2, b_2]$ be a rectangle in the plane, and $a, b \in \mathbb{R}$, $a < b$. We consider the three-dimensional parallelepiped $V = D \times [a, b]$. Denote by $\mathbf{n}$ the outward normal vector field on the boundary ∂V of V (which is defined everywhere except on the edges). By the Leibniz–Newton fundamental theorem of calculus,

$$\begin{aligned}\int_a^b \frac{d}{dt}\iint_D G(x,y,t)dxdydt &= \int_a^b\iint_D \frac{\partial}{\partial t}G(x,y,t)dxdydt\\ &= \iint_D\int_a^b \frac{\partial}{\partial t}G(x,y,t)dtdxdy\\ &= \iint_D G(x,y,b)dxdy - \iint_D G(x,y,a)dxdy\\ &= \iint_{D\times\{b\}} G(x,y,t)\,\mathbf{k}\cdot d\mathbf{n} + \iint_{D\times\{a\}} G(x,y,t)\,\mathbf{k}\cdot d\mathbf{n},\end{aligned}$$

where $\mathbf{k}$ denotes the unit vector that points in the z-direction. With this in mind, we compute

$$0 = \int_a^b\left(\frac{d}{dt}\iint_D G(x,y,t)dxdy + \oint_C \mathbf{F}\cdot d\mathbf{R}\right)dt$$

$$= {}_{D\times\{b\}} G(x,y,t)\,k\cdot d\,n + {}_{D\times\{a\}} G(x,y,t)\,k\cdot d\,n$$

$$+ {}_a^b {}_{a_1}^{b_1} F_1(x,a_2)dx \qquad {}_a^b {}_{b_1}^{a_1} F_1(x,b_2)dx$$

$$+ {}_a^b {}_{a_2}^{b_2} F_2(b_1,y)dy \qquad {}_a^b {}_{b_2}^{a_2} F_2(a_1,y)dy.$$

If we introduce the vector field $H = F_2\, i + F_1\, j + G\, k$, this equation can be written simply as

$${}_V H \cdot n\, dS = 0.$$

By the divergence theorem,

$${}_V \operatorname{div} H\, dV = {}_V H \cdot n\, dS = 0.$$

Since this happens in every parallelepiped, div H must be identically equal to 0. Therefore,

$$\operatorname{div} H = \frac{F_2}{x} + \frac{F_1}{y} + \frac{G}{t} = 0,$$

and the relation is proved.

Remark. The interesting case occurs when F and G depend on spatial variables (spatial dimensions). Then G becomes a vector field B, or better a 2-form, called the magnetic flux, while F becomes the electric field strength E. The relation

$$\frac{d}{dt}\,{}_S B = {}_S E$$

is Faraday's law of induction. Introducing a fourth dimension (the time), and redoing mutatis mutandis the above computation gives rise to the first group of Maxwell's equations

$$\operatorname{div} B = 0, \qquad \frac{B}{t} = \operatorname{curl} E.$$

534. In the solution we ignore the factor $\frac{1}{4}$, which is there only to make the linking number an integer. We will use the more general form of Green's theorem applied to the curve $C = C_1 \quad C_1$ and surface S,

$$5_{C}\, P\,dx + Q dy + R dz = {}_{S}\left(\frac{Q}{x}\quad\frac{P}{y}\right) dx dy + \left(\frac{R}{y}\quad\frac{Q}{z}\right) dy dz$$

$$+\left(\frac{P}{z}\quad\frac{R}{x}\right) dz dx.$$

Writing the parametrization with coordinate functions $v_1(s) = (x(s), y(s), z(s))$, $v_2(t) = (x(t), y(t), z(t))$, the linking number of C_1 and C_2 (with the factor $\frac{1}{4}$ ignored) becomes

$$5_{C_1}\,5_{C_2} \frac{(x \quad x)(dz\, dy \quad dy\, dz) + (y \quad y)(dx\, dz \quad dz\, dx) + (z \quad z)(dy\, dx \quad dx\, dy)}{((x \quad x)^2 + (y \quad y)^2 + (z \quad z)^2)^{3/2}}$$

The 1-form $P dx + Q dy + R dz$, which we integrate on $C = C_1 \quad C_1$, is

$$5_{C_2} \frac{(x \quad x)(dz\, dy \quad dy\, dz) + (y \quad y)(dx\, dz \quad dz\, dx) + (z \quad z)(dy\, dx \quad dx\, dy)}{((x \quad x)^2 + (y \quad y)^2 + (z \quad z)^2)^{3/2}}.$$

Note that here we integrate against the variables x , y , z , so this expression depends only on x, y, and z. Explicitly,

$$P(x, y, z) = 5_{C_2} \frac{(y \quad y)dz + (z \quad z)dy}{((x \quad x)^2 + (y \quad y)^2 + (z \quad z)^2)^{3/2}},$$

$$Q(x, y, z) = 5_{C_2} \frac{(x \quad x)dz \quad (z \quad z)dx}{((x \quad x)^2 + (y \quad y)^2 + (z \quad z)^2)^{3/2}},$$

$$R(x, y, z) = 5_{C_2} \frac{(x \quad x)dy + (y \quad y)dx}{((x \quad x)^2 + (y \quad y)^2 + (z \quad z)^2)^{3/2}}.$$

By the general form of Green s theorem, lk$(C_1, C_2) = $ lk(C_1, C_2) if

$$\frac{Q}{x} \quad \frac{P}{y} = \frac{R}{y} \quad \frac{Q}{z} = \frac{P}{z} \quad \frac{R}{x} = 0.$$

We will verify only $\frac{Q}{x} \quad \frac{P}{y} = 0$, the other equalities having similar proofs. The part of it that contains dz is equal to

$$5_{C_2} \quad 2((x \quad x)^2 + (y \quad y)^2 + (z \quad z)^2) \;^{3/2}$$

$$+ 3(x \quad x)^2((x \quad x)^2 + (y \quad y)^2 + (z \quad z)^2) \;^{5/2}$$

$$+ 3(y \quad y)^2((x \quad x)^2 + (y \quad y)^2 + (z \quad z)^2) \;^{5/2} dz$$

$$= 5_{C_2} \quad ((x \quad x)^2 + (y \quad y)^2 + (z \quad z)^2) \;^{3/2}$$

$$+ 3(z \quad z)^2((x \quad x)^2 + (y \quad y)^2 + (z \quad z)^2) \;^{5/2} dz$$

$$= \overset{5}{}_{C_2} \frac{}{z}((x \quad x)^2 + (y \quad y)^2 + (z \quad z)^2)^{\quad 3/2} dz = 0,$$

where the last equality is a consequence of the fundamental theorem of calculus. Of the two, only $\frac{Q}{x}$ has a dx in it, and that part is

$$3 \overset{5}{}_{C_2} ((x \quad x\ )^2 + (y \quad y\ )^2 + (z \quad z\ )^2)^{\quad 5/2}(x \quad x\ )(z \quad z\ )dx$$

$$= \overset{5}{}_{C_2} \frac{}{x} \frac{z \quad z}{((x \quad x\ )^2 + (y \quad y\ )^2 + (z \quad z\ )^2)^{3/2}} dx = 0.$$

The term involving dy is treated similarly. The conclusion follows.

Remark. The linking number is, in fact, an integer, which measures the number of times the curves wind around each other. It was defined by C.F. Gauss, who used it to decide, based on astronomical observations, whether the orbits of certain asteroids were winding around the orbit of the earth.

535. Plugging in $x = y$, we find that $f(0) = 0$, and plugging in $x = \quad 1$, $y = 0$, we find that $f(1) = \quad f(\quad 1)$. Also, plugging in $x = a$, $y = 1$, and then $x = a$, $y = \quad 1$, we obtain

$$f(a^2 \quad 1) = (a \quad 1)(f(a) + f(1)),$$
$$f(a^2 \quad 1) = (a + 1)(f(a) \quad f(1)).$$

Equating the right-hand sides and solving for $f(a)$ gives $f(a) = f(1)a$ for all a.

So any such function is linear. Conversely, a function of the form $f(x) = kx$ clearly satisfies the equation.

(Korean Mathematical Olympiad, 2000)

536. Replace z by $1 \quad z$ to obtain

$$f(1 \quad z) + (1 \quad z)f(z) = 2 \quad z.$$

Combine this with $f(z) + zf(1 \quad z) = 1 + z$, and eliminate $f(1 \quad z)$ to obtain

$$(1 \quad z + z^2)f(z) = 1 \quad z + z^2.$$

Hence $f(z) = 1$ for all z except maybe for $z = e^{- \ i \ /3}$, when $1 \quad z + z^2 = 0$. For $\quad = e^{i \ /3}$, ﬂ $= \quad ^2 = 1 \quad$; hence $f(\ ) + \quad f($ﬂ$) = 1 + \quad$. We therefore have only one constraint, namely $f($ﬂ$) = [1 + \quad f(\ )]/ \quad =$ ﬂ $+ 1 \quad$ ﬂ $f(\ )$. Hence the solution to the functional equation is of the form

$$f(z) = 1 \quad \text{for } z = e^{-i \ /3},$$

4

Geometry and Trigonometry

Geometry is the oldest of the mathematical sciences. Its age-old theorems and the sharp logic of its proofs make you think of the words of Andrew Wiles, “Mathematics seems to have a permanence that nothing else has.”

This chapter is bound to take you away from the geometry of the ancients, with figures and pictorial intuition, and bring you to the science of numbers and equations that geometry has become today. In a dense exposition we have packed vectors and their applications, analytical geometry in the plane and in space, some applications of integral calculus to geometry, followed by a list of problems with Euclidean flavor but based on algebraic and combinatorial ideas. Special attention is given to conics and quadrics, for their study already contains the germs of differential and algebraic geometry.

Four subsections are devoted to geometry's little sister, trigonometry. We insist on trigonometric identities, repeated in subsequent sections from different perspectives: Euler's formula, trigonometric substitutions, and telescopic summation and multiplication.

Since geometry lies at the foundation of mathematics, its presence could already be felt in the sections on linear algebra and multivariable calculus. It will resurface again in the chapter on combinatorics.

4.1 Geometry

4.1.1 Vectors

This section is about vectors in two and three dimensions. Vectors are oriented segments identified under translation.

There are four operations defined for vectors: scalar multiplication v, addition $v + w$, dot product $v \cdot w$, and cross-product $v \times w$, the last being defined only in three dimensions. Scalar multiplication dilates or contracts a vector by a scalar. The sum of two vectors is computed with the parallelogram rule; it is the resultant of the vectors acting as forces on an object. The dot product of two vectors is a number equal to the product of the magnitudes of the vectors and the cosine of the angle between them. A dot product equal to zero tells us that the vectors are orthogonal. The cross-product of two vectors is a vector orthogonal to the two vectors and of magnitude equal to the area of the parallelogram they generate. The orientation of the cross-product is determined by the right-hand rule: place your hand so that you can bend your palm from the first vector to the second, and your thumb will point in the direction of the cross-product. A cross-product equal to zero tells us that the vectors are parallel (although they might point in opposite directions).

The dot and cross-products are distributive with respect to sum; the dot product is commutative, while the cross-product is not. For the three-dimensional vectors u, v, w, the number $u\cdot(v\times w)$ is the volume taken with sign of the parallelepiped constructed with the vectors as edges. The sign is positive if the three vectors determine a frame that is oriented the same way as the orthogonal frame of the three coordinate axes, and negative otherwise. Equivalently, $u\cdot(v\times w)$ is the determinant with the coordinates of the three vectors as rows.

A useful computational tool is the *cab-bac* identity:

$$a\times(b\times c)=(c\cdot a)b-(b\cdot a)c.$$

The quickest way to prove it is to check it for a, b, c chosen among the three unit vectors parallel to the coordinate axes i, j, and k, and then use the distributivity of the cross-product with respect to addition. Here is an easy application of this identity.

Example. Prove that for any vectors a, b, c, d,

$$(a\times b)\times(c\times d)=(a\cdot(b\times d))c-(a\cdot(b\times c))d.$$

Solution. We have

$$\begin{aligned}(a\times b)\times(c\times d)&=(d\cdot(a\times b))c-(c\cdot(a\times b))d\\&=(a\cdot(b\times d))c-(a\cdot(b\times c))d.\end{aligned}$$

In the computation we used the equality $u\cdot(v\times w)=w\cdot(u\times v)$, which is straightforward if we write these as determinants.

Let us briefly point out a fundamental algebraic property of the cross-product. Denote by so(3) the set of 3 × 3 matrices A satisfying $A+A^t=O_3$ endowed with the operation $[A,B]=AB-BA$.

Theorem. *The map*

$$(a_1,a_2,a_3)\mapsto\begin{pmatrix}0 & a_1 & a_2\\ -a_1 & 0 & a_3\\ -a_2 & -a_3 & 0\end{pmatrix}$$

establishes an isomorphism between $(\mathbb{R}^3, \times)$ *and* $(so(3), [\cdot,\cdot])$.

Proof. The proof is straightforward if we write the cross-product in coordinates. The result shows that the cross-product defines a Lie algebra structure on the set of three-dimensional vectors. Note that the isomorphism maps the sum of vectors to the sum of matrices, and the dot product of two vectors to the negative of half the trace of the product of the corresponding matrices.

And now the problems.

573. For any three-dimensional vectors u, v, w, prove the identity

$$u \times (v \times w) + v \times (w \times u) + w \times (u \times v) = 0.$$

574. Given three vectors a, b, c, define

$$u = (b \cdot c)a \quad (c \cdot a)b,$$
$$v = (a \cdot c)b \quad (a \cdot b)c,$$
$$w = (b \cdot a)c \quad (b \cdot c)a.$$

Prove that if a, b, c form a triangle, then u, v, w also form a triangle, and this triangle is similar to the first.

575. Let a, b, c be vectors such that b and c are perpendicular, but a and b are not. Let m be a real number. Solve the system

$$x \cdot a = m,$$
$$x \times b = c.$$

576. Consider three linearly independent vectors a, b, c in space, having the same origin. Prove that the plane determined by the endpoints of the vectors is perpendicular to the vector $a \times b + b \times c + c \times a$.

577. The vectors a, b, and c satisfy

$$a \times b = b \times c = c \times a = 0.$$

Prove that $a + b + c = 0$.

578. Find the vector-valued functions $u(t)$ satisfying the differential equation

$$u \times u = v,$$

where $v = v(t)$ is a twice-differentiable vector-valued function such that both v and v are never zero or parallel.

579. Does there exist a bijection f of (a) a plane with itself or (b) three-dimensional space with itself such that for any distinct points A, B the lines AB and $f(A)f(B)$ are perpendicular?

580. On so(3) we define the operation such that if A and B are matrices corresponding to the vectors $a = (a_1, a_2, a_3)$ and $b = (b_1, b_2, b_3)$, then the ij entry of $A \quad B$ is equal to $(\quad 1)^{i+j} a_{4 \ j} b_{4 \ i}$. Prove the identity

$$CBA \quad BCA = (A \quad C)B \quad (A \quad B)C.$$

581. Prove that there is a bijection f from R^3 to the set su(2) of 2 × 2 matrices with complex entries that are skew symmetric and have trace equal to zero such that

$$f(v \times w) = [f(v), f(w)].$$

We present two applications of vector calculus to geometry, one with the dot product, one with the cross-product.

Example. Given two triangles ABC and $A B C$ such that the perpendiculars from A, B, C onto $B C$, $C A$, $A B$ intersect, show that the perpendiculars from A, B, C onto BC, CA, AB also intersect.

Solution. This is the *property of orthological triangles*. Denote by O the intersection of the first set of three perpendiculars, and by O the intersection of perpendiculars from A and B. Note that if the vector XY is orthogonal to a vector ZW, then for any point P in the plane,

$$(PX \quad PY) \cdot ZW = XY \cdot ZW = 0;$$

hence $PX \cdot ZW = PY \cdot ZW$. Using this fact we can write

$$O C \cdot OB = O A \cdot OB = O A \cdot OC = O B \cdot OC = O B \cdot OA = O C \cdot OA.$$

Therefore, $O C \cdot (OB \quad OA) = O C \cdot AB = 0$, which shows that $O C$ is perpendicular to AB. This proves that the second family of perpendiculars are concurrent.

Example. Let $ABCD$ be a convex quadrilateral, M, N on side AB and P, Q on side CD. Show that if $AM = NB$ and $CP = QD$, and if the quadrilaterals $AMQD$ and $BNPC$ have the same area, then AB is parallel to CD.

Solution. Throughout the solution we refer to Figure 24. We decompose the quadrilaterals into triangles, and then use the formula for the area in terms of the cross-product.

In general, the triangle determined by v_1 and v_2 has area equal to half the magnitude of $v_1 \times v_2$. Note also that $v_1 \times v_2$ is perpendicular to the plane of the triangle, so for

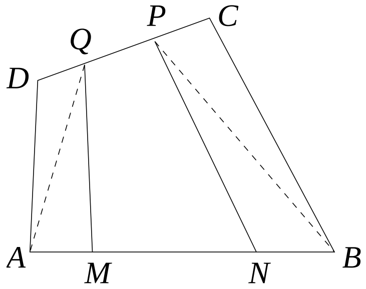

Figure 24

a problem in plane geometry there is no danger in identifying the areas with the cross-products, provided that we keep track of the orientation. The hypothesis of the problem implies that

$$\frac{1}{2}(DA \times DQ + AM \times AQ) = \frac{1}{2}(CP \times CB + BP \times BN).$$

Hence

$$DA \times DQ + AM \times (AD + DQ) = CP \times CB + (BC + CP) \times BN.$$

Because $BN = \quad AM$ and $CP = \quad DQ$, this equality can be rewritten as

$$(AM + DQ) \times (AD + CB) = 2DQ \times AM.$$

Using the fact that $AD + CB = AB + CD$ (which follows from $AB + BC + CD + DA = 0$), we obtain

$$AM \times CD + DQ \times AB = 2DQ \times AM.$$

From here we deduce that $AM \times QC = DQ \times MB$. These two cross-products point in opposite directions, so equality can hold only if both are equal to zero, i.e., if AB is parallel to CD.

More applications of the dot and cross-products to geometry can be found below.

582. Given two triangles ABC and $A\ B\ C$ with the same centroid, prove that one can construct a triangle with sides equal to the segments AA , BB , and CC .

583. Given a quadrilateral $ABCD$, consider the points A , B , C , D on the half-lines (i.e., rays) $|AB$, $|BC$, $|CD$, and $|DA$, respectively, such that $AB = BA$, $BC = CB$, $CD = DC$, $DA = AD$. Suppose now that we start with the quadrilateral $A\ B\ C\ D$. Using a straightedge and a compass only, reconstruct the quadrilateral $ABCD$.

584. On the sides of the triangle ABC construct in the exterior the rectangles ABB_1A_2, BCC_1B_2, CAA_1C_2. Prove that the perpendicular bisectors of A_1A_2, B_1B_2, and C_1C_2 intersect at one point.

585. Let $ABCD$ be a convex quadrilateral. The lines parallel to AD and CD through the orthocenter H of triangle ABC intersect AB and BC, respectively, at P and Q. Prove that the perpendicular through H to the line PQ passes through the orthocenter of triangle ACD.

586. Prove that if the four lines through the centroids of the four faces of a tetrahedron perpendicular to those faces are concurrent, then the four altitudes of the tetrahedron are also concurrent. Prove that the converse is also true.

587. Let ABC be a convex quadrilateral, M, N AB such that $AM = MN = NB$, and P, Q CD such that $CP = PQ = QD$. Let O be the intersection of AC and BD. Prove that the triangles MOP and NOQ have the same area.

588. Let ABC be a triangle, with D and E on the respective sides AC and AB. If M and N are the midpoints of BD and CE, prove that the area of the quadrilateral $BCDE$ is four times the area of the triangle AMN.

4.1.2 The Coordinate Geometry of Lines and Circles

Coordinate geometry was constructed by Descartes to translate Euclid's geometry into the language of algebra. In two dimensions one starts by fixing two intersecting coordinate axes and a unit on each of them. If the axes are perpendicular and the units are equal, the coordinates are called Cartesian (in the honor of Descartes); otherwise, they are called affine. A general affine change of coordinates has the form

$$\begin{matrix}x\\y\end{matrix} = \begin{matrix}a&b\\c&d\end{matrix}\;\begin{matrix}x\\y\end{matrix} + \begin{matrix}e\\f\end{matrix}, \quad \text{with} \quad \begin{matrix}a&b\\c&d\end{matrix} \quad \text{invertible.}$$

If the change is between Cartesian systems of coordinates, a so-called Euclidean change of coordinates, it is required additionally that the matrix

$$\begin{matrix}a&b\\c&d\end{matrix}$$

be orthogonal, meaning that its inverse is equal to the transpose.

Properties that can be formulated in the language of lines and ratios are invariant under affine changes of coordinates. Such are the properties of two lines being parallel or of a point to divide a segment in half. All geometric properties are invariant under Euclidean changes of coordinates. Therefore, problems about distances, circles, and angles should be modeled with Cartesian coordinates.

In this section we grouped problems that require only the knowledge of the theory of lines and circles. Recall that the general equation of a line (whether in a Cartesian or affine coordinate system) is $ax + by + c = 0$. That of a circle (in a Cartesian coordinate system) is $(x - h)^2 + (y - k)^2 = r^2$, where (h, k) is the center and r is the radius. Let us see two examples, one in affine and one in Cartesian coordinates. But before we do that let us recall that a complete quadrilateral is a quadrilateral in which the pairs of opposite sides have been extended until they meet. For that reason, a complete quadrilateral has six vertices and three diagonals.

Example. Prove that the midpoints of the three diagonals of a complete quadrilateral are collinear.

Solution. As said, we will work in affine coordinates. Choose the coordinate axes to be sides of the quadrilateral, as shown in Figure 25.

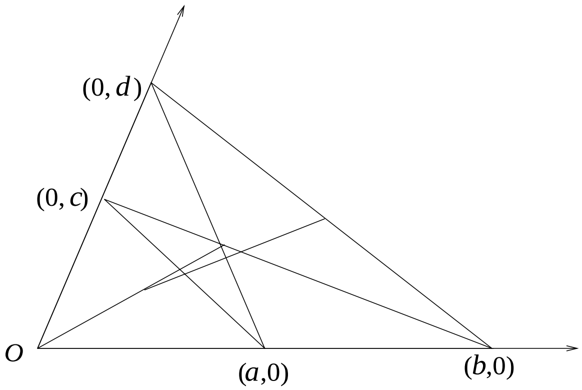

Figure 25

Five of the vertices have coordinates $(0, 0)$, $(a, 0)$, $(b, 0)$, $(0, c)$, and $(0, d)$, while the sixth is found as the intersection of the lines through $(a, 0)$ and $(0, d)$, respectively, $(0, c)$ and $(b, 0)$. For these two lines we know the x- and y-intercepts, so their equations are

$$\frac{1}{a}x + \frac{1}{d}y = 1 \quad \text{and} \quad \frac{1}{b}x + \frac{1}{c}y = 1.$$

The sixth vertex of the complete quadrilateral has therefore the coordinates

$$\left(\frac{ab(c - d)}{ac - bd}, \frac{cd(a - b)}{ac - bd}\right).$$

We find that the midpoints of the diagonals are

$$\left(\frac{a}{2}, \frac{c}{2}\right), \quad \left(\frac{b}{2}, \frac{d}{2}\right), \quad \left(\frac{ab(c - d)}{2(ac - bd)}, \frac{cd(a - b)}{2(ac - bd)}\right).$$

The condition that these three points be collinear translates to

$$\frac{1}{2(ac-bd)}\begin{vmatrix} a & c & 1 \\ b & d & 1 \\ ab(c-d) & cd(a-b) & ac-bd \end{vmatrix} = 0.$$

This is verified by direct computation.

Example. In a circle are inscribed a trapezoid with one side as diameter and a triangle with sides parallel to the sides of the trapezoid. Prove that the two have the same area.

Solution. We refer everything to Figure 26. Assume that the circle has radius 1, and the trapezoid has vertices $(1,0)$, (a,b), $(-a,b)$ and $(-1,0)$.

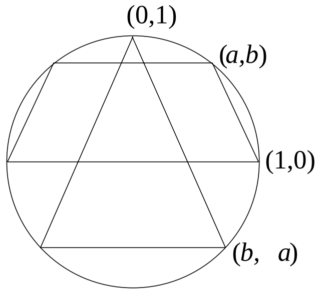

Figure 26

The triangle is isosceles and has one vertex at $(0,1)$. We need to determine the coordinates of the other two vertices. One of them lies where the parallel through $(0,1)$ to the line determined by $(1,0)$ and (a,b) intersects the circle. The equation of the line is

$$y = \frac{b}{a-1}x + 1.$$

The relation $a^2 + b^2 = 1$ yields $b^2 = (1-a)(1+a)$, or $\frac{b}{1-a} = \frac{1+a}{b}$. So the equation of the line can be rewritten as

$$y = -\frac{1+a}{b}x + 1.$$

Now it is easy to guess that the intersection of this line with the circle is $(b,-a)$ (note that this point satisfies the equation of the circle). The other vertex of the triangle is $(-b,-a)$, so the area is $\frac{1}{2}(2b)(1+a) = b + ab$. And the area of the trapezoid is $\frac{1}{2}(2a+2)b = b + ab$, the same number.

589. Prove that the midpoints of the sides of a quadrilateral form a parallelogram.

590. Let M be a point in the plane of triangle ABC. Prove that the centroids of the triangles MAB, MAC, and MCB form a triangle similar to triangle ABC.

591. Find the locus of points P in the interior of a triangle ABC such that the distances from P to the lines AB, BC, and CA are the side lengths of some triangle.

592. Let $A_1, A_2, \dots, A_n$ be distinct points in the plane, and let m be the number of midpoints of all the segments they determine. What is the smallest value that m can have?

593. Given an acute-angled triangle ABC with altitude AD, choose any point M on AD, and then draw BM and extend until it intersects AC in E, and draw CM and extend until it intersects AB in F. Prove that $\ ADE = \ ADF$.

594. In a planar Cartesian system of coordinates consider a fixed point $P(a, b)$ and a variable line through P. Let A be the intersection of the line with the x-axis. Connect A with the midpoint B of the segment OP (O being the origin), and through C, which is the point of intersection of this line with the y-axis, take the parallel to OP. This parallel intersects PA at M. Find the locus of M as the line varies.

595. Let $ABCD$ be a parallelogram with unequal sides. Let E be the foot of the perpendicular from B to AC. The perpendicular through E to BD intersects BC in F and AB in G. Show that $EF = EG$ if and only if $ABCD$ is a rectangle.

596. Find all pairs of real numbers (p, q) such that the inequality

$$\overline{1 \quad x^2} \quad px \quad q \qquad \frac{\overline{2} \quad 1}{2}$$

holds for every $x \quad [0, 1]$.

597. On the hyperbola $xy = 1$ consider four points whose x-coordinates are x_1, x_2, x_3, and x_4. Show that if these points lie on a circle, then $x_1x_2x_3x_4 = 1$.

The points of the plane can be represented as complex numbers. There are two instances in which complex coordinates come in handy: in problems involving nice angles (such as $\frac{}{4}, \frac{}{3}, \frac{}{2}$), and in problems about regular polygons.

In complex coordinates the line passing through the points z_1 and z_2 has the parametric equation $z = tz_1 + (1 \quad t)z_2$, $t \quad \mathbb{R}$. Also, the angle between the line passing through z_1 and z_2 and the line passing through z_3 and z_4 is the argument of the complex number $\frac{z_1 \quad z_2}{z_3 \quad z_4}$. The length of the segment determined by the points z_1 and z_2 is $|z_1 \quad z_2|$. The vertices of a regular n-gon can be chosen, up to a scaling factor, as $1, \ , \ ^2, \dots, \ ^{n \ 1}$, where $\ = e^{2 \ i/n} = \cos\frac{2}{n} + i \sin\frac{2}{n}$.

Example. Let ABC and BCD be two equilateral triangles sharing one side. A line passing through D intersects AC at M and AB at N. Prove that the angle between the lines BM and CN is $\frac{\pi}{3}$.

Solution. In the complex plane, let B have the coordinate 0, and C the coordinate 1. Then A and D have the coordinates $e^{i\pi/3}$ and $e^{-i\pi/3}$, respectively, and N has the coordinate $te^{i\pi/3}$ for some real number t.

The parametric equations of ND and AC are, respectively,

$$z = \alpha te^{i\pi/3} + (1-\alpha)e^{-i\pi/3} \quad\text{and}\quad z = \beta e^{i\pi/3} + (1-\beta), \quad \alpha, \beta \in \mathbb{R}.$$

To find their intersection we need to determine the real numbers α and β such that

$$\alpha te^{i\pi/3} + (1-\alpha)e^{-i\pi/3} = \beta e^{i\pi/3} + (1-\beta).$$

Explicitly, this equation is

$$\alpha t\frac{1+i\sqrt{3}}{2} + (1-\alpha)\frac{1-i\sqrt{3}}{2} = \beta\frac{1+i\sqrt{3}}{2} + (1-\beta).$$

Setting the real and imaginary parts equal, we obtain the system

$$\begin{aligned} \alpha t + (1-\alpha) &= \beta + 2(1-\beta), \\ \alpha t - (1-\alpha) &= \beta. \end{aligned}$$

By adding the two equations, we obtain $\alpha = \frac{1}{t}$. So the complex coordinate of M is $e^{i\pi/3} + (1-\frac{1}{t})e^{-i\pi/3}$.

The angle between the lines BM and CN is the argument of the complex number

$$\frac{e^{i\pi/3} + \left(1-\frac{1}{t}\right)e^{-i\pi/3}}{te^{i\pi/3}-1} = \frac{e^{i\pi/3} + e^{-i\pi/3} - \frac{1}{t}e^{-i\pi/3}}{te^{i\pi/3}-1} = \frac{1-\frac{1}{t}e^{-i\pi/3}}{te^{i\pi/3}-1} = \frac{1}{t}e^{-i\pi/3}.$$

The angle is therefore $\frac{\pi}{3}$, as claimed.

During the Mathematical Olympiad Summer Program of 2006, J. Bland discovered the following simpler solution:

Place the figure in the complex plane so that the coordinates of A, B, C, D are, respectively, $i\sqrt{3}$, -1, 1, and $-i\sqrt{3}$. Let MC have length $2t$, where t is a real parameter (positive if C is between A and M and negative otherwise). The triangles MCD and NBD have parallel sides, so they are similar. It follows that $BN = \frac{2}{t}$ (positive if B is between A and N and negative otherwise). The coordinates of M and N are

$$m = -\left(1+\frac{1}{t}\right) - \frac{1}{t}i\sqrt{3} \quad\text{and}\quad n = (t+1) - ti\sqrt{3}.$$

We compute

$$\frac{c \quad n}{b \quad m} = t\frac{2t + 1 + i \quad \overline{3}}{t \quad 2 + ti \quad \overline{3}} = \quad te^{i \frac{}{3}}.$$

It follows that the two lines form an angle of $\frac{}{3}$, as desired.

The second example comes from the 15th W.L. Putnam Mathematical Competition, 1955.

Example. Let $A_1A_2A_3 \ldots A_n$ be a regular polygon inscribed in the circle of center O and radius r. On the half-line $|OA_1$ choose the point P such that A_1 is between O and P. Prove that

$$\overset{n}{\underset{i=1}{}} PA_i = PO^n \quad r^n.$$

Solution. Place the vertices in the complex plane such that $A_i = r \ ^i$, $1 \quad i \quad n$, where is an nth root of unity. The coordinate of P is a real number rx, with $x > 1$. We have

$$\overset{n}{\underset{i=1}{}} PA_i = \overset{n}{\underset{i=1}{}} |rx \quad r \ ^i| = r^n \overset{n}{\underset{i=1}{}} |x \quad ^i| = r^n \overset{n}{\underset{i=1}{}} (x \quad ^i)$$
$$= r^n(x^n \quad 1) = (rx)^n \quad r^n = PO^n \quad r^n.$$

The identity is proved.

598. Let $ABCDEF$ be a hexagon inscribed in a circle of radius r. Show that if $AB = CD = EF = r$, then the midpoints of BC, DE, and FA are the vertices of an equilateral triangle.

599. Prove that in a triangle the orthocenter H, centroid G, and circumcenter O are collinear. Moreover, G lies between H and O, and $\frac{OG}{GH} = \frac{1}{2}$.

600. On the sides of a convex quadrilateral $ABCD$ one draws outside the equilateral triangles ABM and CDP and inside the equilateral triangles BCN and ADQ. Describe the shape of the quadrilateral $MNPQ$.

601. Let ABC be a triangle. The triangles PAB and QAC are constructed outside of the triangle ABC such that $AP = AB$, $AQ = AC$, and $\quad BAP = \quad CAQ = \quad$. The segments BQ and CP meet at R. Let O be the circumcenter of the triangle BCR. Prove that AO and PQ are orthogonal.

602. Let $A_1A_2 \ldots A_n$ be a regular polygon with circumradius equal to 1. Find the maximum value of $\overset{n}{\underset{k=1}{}} PA_k$ as P ranges over the circumcircle.

603. Let $A_0, A_1, \ldots, A_n$ be the vertices of a regular n-gon inscribed in the unit circle. Prove that

$$A_0A_1 \cdot A_0A_2 \cdots A_0A_{n\quad 1} = n.$$

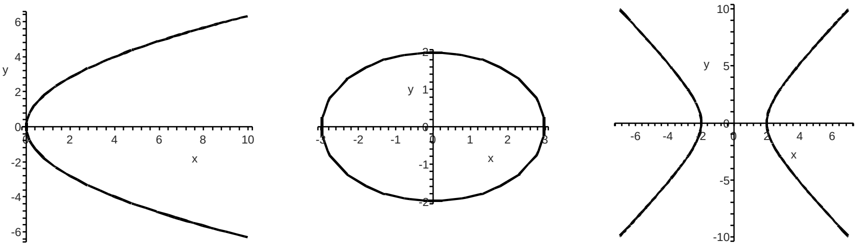
4.1.3 Conics and Other Curves in the Plane

The general equation of a quadratic curve is

$$ax^2 + by^2 + cxy + dx + ey + f = 0.$$

Such a curve is called a conic because (except for the degenerate case of two parallel lines) it can be obtained by sectioning a circular cone by a plane.

The degenerate conics are pairs of (not necessarily distinct) lines, single points, the entire plane, and the empty set. We ignore them. There are three types of nondegenerate conics, which up to a change of Cartesian coordinates are described in Figure 27.



$y^2 = 4px$
parabola

$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$
ellipse

$\frac{x^2}{a^2} \quad \frac{y^2}{b^2} = 1$
hyperbola

Figure 27

The parabola is the locus of the points at equal distance from the point $(p, 0)$ (focus) and the line $x = \quad p$ (directrix). The ellipse is the locus of the points with the sum of distances to the foci $(c, 0)$ and $(\quad c, 0)$ constant, where $c = \quad \overline{|a^2 \quad b^2|}$. The hyperbola is the locus of the points with the difference of the distances to the foci $(c, 0)$ and $(\quad c, 0)$ constant, where $c = \quad \overline{a^2 + b^2}$.

Up to an affine change of coordinates, the equations of the parabola, ellipse, and hyperbola are, respectively, $y^2 = x$, $x^2 + y^2 = 1$, and $x^2 \quad y^2 = 1$. Sometimes it is more convenient to bring the hyperbola into the form $xy = 1$ by choosing its asymptotes as the coordinate axes.

As conic sections, these curves are obtained by sectioning the circular cone $z^2 = x^2 + y^2$ by the planes $z \quad x = 1$ (parabola), $z = 1$ (ellipse), and $y = 1$ (hyperbola). The vertex of the cone can be thought of as the viewpoint of a person. The projections through this viewpoint of one plane to another are called projective transformations. Up to a projective transformation there is only one nondegenerate conic—the circle. Any projectively invariant property that can be proved for the circle is true for any conic (and by passing to the limit, even for degenerate conics). Such is the case with Pascal's theorem: The opposite sides of a hexagon inscribed in a conic meet at three collinear points. Note that when the conic degenerates into two parallel lines, this becomes Pappus' theorem.

To conclude our discussion, let us recall that the equation of the tangent line to a conic at a point (x_0, y_0) is obtained by replacing in the general equation of the conic x^2 and y^2 by xx_0, respectively, yy_0, xy by $\frac{xy_0+yx_0}{2}$, and x and y in the linear terms by $\frac{x+x_0}{2}$, respectively, $\frac{y+y_0}{2}$.

We now proceed with an example from A. Myller's *Analytical Geometry* (3rd ed., Editura Didactica şi Pedagogica, Bucharest, 1972).

Example. Find the locus of the centers of the equilateral triangles inscribed in the parabola $y^2 = 4px$.

Solution. Let us determine first some algebraic conditions that the coordinates (x_i, y_i), $i = 1, 2, 3$, of the vertices of a triangle should satisfy in order for the triangle to be equilateral. The equation of the median from (x_3, y_3) is

$$\frac{y - y_3}{x - x_3} = \frac{y_1 + y_2 - 2y_3}{x_1 + x_2 - 2x_3}.$$

Requiring the median to be orthogonal to the side yields

$$\frac{y_1 + y_2 - 2y_3}{x_1 + x_2 - 2x_3} \cdot \frac{y_2 - y_1}{x_2 - x_1} = -1,$$

or

$$(x_1 - x_2)(x_1 + x_2 - 2x_3) + (y_1 - y_2)(y_1 + y_2 - 2y_3) = 0.$$

So this relation along with the two obtained by circular permutations of the indices are necessary and sufficient conditions for the triangle to be equilateral. Of course, the third condition is redundant. In the case of three points on the parabola, namely $(\frac{y_i^2}{4p}, y_i)$, $i = 1, 2, 3$, after dividing by $y_1 - y_2$, respectively, by $y_2 - y_3$ (which are both nonzero), we obtain

$$(y_1 + y_2)(y_1^2 + y_2^2 - 2y_3^2) + 16p^2(y_1 + y_2 - 2y_3) = 0,$$
$$(y_2 + y_3)(y_2^2 + y_3^2 - 2y_1^2) + 16p^2(y_2 + y_3 - 2y_1) = 0.$$

Subtracting the two gives

$$y_1^3 - y_3^3 + (y_1 - y_3)(y_2^2 - 2y_1y_3) + 48p^2(y_1 - y_3) = 0.$$

Divide this by $y_1 - y_3 \neq 0$ to transform it into

$$y_1^2 + y_2^2 + y_3^2 + 3(y_1y_2 + y_2y_3 + y_3y_1) + 48p^2 = 0.$$

This is the condition satisfied by the y-coordinates of the vertices of the triangle. Keeping in mind that the coordinates of the center of the triangle are

$$x = \frac{y_1^2 + y_2^2 + y_3^2}{12p}, \quad y = \frac{y_1 + y_2 + y_2}{3},$$

we rewrite the relation as

$$\frac{1}{2}(y_1^2 + y_2^2 + y_3^2) + \frac{3}{2}(y_1 + y_2 + y_3)^2 + 48p^2 = 0,$$

then substitute $12px = y_1^2 + y_2^2 + y_3^2$ and $3y = y_1 + y_2 + y_3$ to obtain the equation of the locus

$$-6px + \frac{27}{2}y^2 + 48p^2 = 0,$$

or

$$y^2 = \frac{4p}{9}(x - 8p).$$

This is a parabola with vertex at $(8p, 0)$ and focus at $((\frac{1}{9} + 8)p, 0)$.

The second problem was given at the 1977 Soviet Union University Student Mathematical Olympiad.

Example. Let P be a point on the hyperbola $xy = 4$, and Q a point on the ellipse $x^2 + 4y^2 = 4$. Prove that the distance from P to Q is greater than 1.

Solution. We will separate the conics by two parallel lines at a distance greater than 1. For symmetry reasons, it is natural to try the tangent to the hyperbola at the point $(2, 2)$. This line has the equation $y = 4 - x$.

Let us determine the point in the first quadrant where the tangent to the ellipse has slope -1. If (x_0, y_0) is a point on the ellipse, then the equation of the tangent at x is $xx_0 + 4yy_0 = 4$. Its slope is $-x_0/4y_0$. Setting $-x_0/4y_0 = -1$ and $x_0^2 + 4y_0^2 = 4$, we obtain $x_0 = 4/\sqrt{5}$ and $y_0 = 1/\sqrt{5}$. Consequently, the tangent to the ellipse is $y = \sqrt{5} - x$.

The distance between the lines $y = 4 - x$ and $y = \sqrt{5} - x$ is equal to $(4 - \sqrt{5})/\sqrt{2}$, which is greater than 1. Hence the distance between the arbitrary points P and Q is also greater than 1, and we are done.

604. Consider a circle of diameter AB and center O, and the tangent t at B. A variable tangent to the circle with contact point M intersects t at P. Find the locus of the point Q where the line OM intersects the parallel through P to the line AB.

605. On the axis of a parabola consider two fixed points at equal distance from the focus. Prove that the difference of the squares of the distances from these points to an arbitrary tangent to the parabola is constant.

606. With the chord PQ of a hyperbola as diagonal, construct a parallelogram whose sides are parallel to the asymptotes. Prove that the other diagonal of the parallelogram passes through the center of the hyperbola.

607. A straight line cuts the asymptotes of a hyperbola in points A and B and the hyperbola itself in P and Q. Prove that $AP = BQ$.

608. Consider the parabola $y^2 = 4px$. Find the locus of the points such that the tangents to the parabola from those points make a constant angle .

609. Let T_1, T_2, T_3 be points on a parabola, and t_1, t_2, t_3 the tangents to the parabola at these points. Compute the ratio of the area of triangle $T_1T_2T_3$ to the area of the triangle determined by the tangents.

610. Three points A, B, C are considered on a parabola. The tangents to the parabola at these points form a triangle MNP (NP being tangent at A, PM at B, and MN at C). The parallel through B to the symmetry axis of the parabola intersects AC at L.

(a) Show that $LMNP$ is a parallelogram.

(b) Show that the circumcircle of triangle MNP passes through the focus F of the parabola.

(c) Assuming that L is also on this circle, prove that N is on the directrix of the parabola.

(d) Find the locus of the points L if AC varies in such a way that it passes through F and is perpendicular to BF.

611. Find all regular polygons that can be inscribed in an ellipse with unequal semiaxes.

612. We are given the parabola $y^2 = 2px$ with focus F. For an integer n 3 consider a regular polygon $A_1A_2\ldots A_n$ whose center is F and such that none of its vertices is on the x-axis. The half-lines $|FA_1$, $|FA_2$, …, $|FA_n$ intersect the parabola at B_1, B_2, …, B_n. Prove that

$$FB_1 + FB_2 + \cdots + FB_n \quad np.$$

613. A *cevian* of a triangle is a line segment that joins a vertex to the line containing the opposite side. An *equicevian point* of a triangle ABC is a point P (not necessarily inside the triangle) such that the cevians on the lines AP, BP, and CP have equal lengths. Let SBC be an equilateral triangle, and let A be chosen in the interior of SBC, on the altitude dropped from S.

(a) Show that ABC has two equicevian points.
(b) Show that the common length of the cevians through either of the equicevian points is constant, independent of the choice of A.
(c) Show that the equicevian points divide the cevian through A in a constant ratio, which is independent of the choice of A.
(d) Find the locus of the equicevian points as A varies.
(e) Let S' be the reflection of S in the line BC. Show that (a), (b), and (c) hold if A varies on any ellipse with S and S' as its foci. Find the locus of the equicevian points as A varies on the ellipse.

A planar curve is called rational if it can be parametrized as $(x(t), y(t))$ with $x(t)$ and $y(t)$ rational functions of the real variable t. Here we have to pass to the closed real line, so t is allowed to be infinite, while the plane is understood as the projective plane, zero denominators giving rise to points on the line at infinity.

Theorem. *All conics are rational curves.*

Proof. The case of degenerate conics (i.e., pairs of lines) is trivial. The parabola $y^2 = 4px$ is parametrized by $(\frac{t^2}{4p}, t)$, the ellipse $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$ by $(a\frac{1-t^2}{1+t^2}, b\frac{2t}{1+t^2})$, and the hyperbola $\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$ by $(a\frac{t+t^{-1}}{2}, b\frac{t-t^{-1}}{2})$. The general case follows from the fact that coordinate changes are rational (in fact, linear) transformations.

Compare the standard parametrization of the circle $(\cos x, \sin x)$ to the rational parametrization $(\frac{1-t^2}{1+t^2}, \frac{2t}{1+t^2})$. This gives rise to the trigonometric substitution $\tan \frac{x}{2} = t$ and explains why integrals of the form

$$\int R(\cos x, \sin x)dx,$$

with R a two-variable rational function, can be reduced to integrals of rational functions.

Let us change slightly our point of view and take a look at the conic

$$y^2 = ax^2 + bx + c.$$

If we fix a point (x_0, y_0) on this conic, the line $y - y_0 = t(x - x_0)$ intersects the conic in exactly one more point (x, y). Writing the conditions that this point is both on the line and on the conic and eliminating y, we obtain the equation

$$[y_0 + t(x - x_0)]^2 = ax^2 + bx + c.$$

A few algebraic computations yield

$$2y_0t + t^2(x - x_0) = a(x + x_0) + b.$$

This shows that x is a rational function of the slope t. The same is true for y. As t varies, (x, y) describes the whole conic. This is a rational parametrization of the conic, giving rise to Euler's substitutions. In their most general form, Euler's substitutions are

$$\sqrt{ax^2 + bx + c} - y_0 = t(x - x_0).$$

They are used for rationalizing integrals of the form

$$\int R(x, \sqrt{ax^2 + bx + c})dx,$$

where R is a two-variable rational function.

614. Compute the integral

$$\int \frac{dx}{a + b\cos x + c\sin x},$$

where a, b, c are real numbers, not all equal to zero.

615. Consider the system

$$x + y = z + u,$$
$$2xy = zu.$$

Find the greatest value of the real constant m such that $m \le \frac{x}{y}$ for any positive integer solution (x, y, z, u) of the system, with $x \ge y$.

We conclude our incursion into two-dimensional geometry with an overview of various famous planar curves. The first answers a question of G.W. Leibniz.

Example. What is the path of an object dragged by a string of constant length when the end of the string not joined to the object moves along a straight line?

Solution. Assume that the object is dragged by a string of length 1, that its initial coordinates are $(0, 1)$, and that it is dragged by a vehicle moving along the x-axis in the positive direction. Observe that the slope of the tangent to the curve at a point (x, y) points toward the vehicle, while the distance to the vehicle is always equal to 1. These two facts can be combined in the differential equation

$$\frac{dy}{dx} = -\frac{y}{\sqrt{1 - y^2}}.$$

Separate the variables

$$dx = \quad \frac{\overline{1 \quad y^2}}{y} dy,$$

and then integrate to obtain

$$x = \quad \overline{1 \quad y^2} \quad \ln y \quad \ln(1 + \quad \overline{1 \quad y^2}) + C.$$

The initial condition gives $C = 0$. The answer to the problem is therefore the curve

$$x = \quad \overline{1 \quad y^2} \quad \ln y \quad \ln(1 + \quad \overline{1 \quad y^2}),$$

depicted in Figure 28.

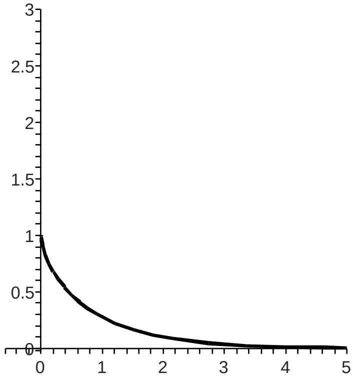


Figure 28

This curve is called a *tractrix*, a name given by Ch. Huygens. Clearly, it has the x-axis as an asymptote. E. Beltrami has shown that the surface of revolution of the tractrix around its asymptote provides a partial model for hyperbolic geometry. This surface has been used in recent years for the shape of loudspeakers.

A variety of other curves show up in the problems below. In some of the solutions, polar coordinates might be useful. Recall the formulas for changing between Cartesian and polar coordinates: $x = r \cos \quad$, $y = r \sin \quad$.

616. Find the points where the tangent to the cardioid $r = 1 + \cos \quad$ is vertical.

617. Given a circle of diameter AB, a variable secant through A intersects the circle at C and the tangent through B at D. On the half-line AC a point M is chosen such that $AM = CD$. Find the locus of M.

618. Find the locus of the projection of a fixed point on a circle onto the tangents to the circle.

619. On a circle of center O consider a fixed point A and a variable point M. The circle of center A and radius AM intersects the line OM at L. Find the locus of L as M varies on the circle.

620. The endpoints of a variable segment AB lie on two perpendicular lines that intersect at O. Find the locus of the projection of O onto AB, provided that the segment AB maintains a constant length.

621. From the center of a rectangular hyperbola a perpendicular is dropped to a variable tangent. Find the locus in polar coordinates of the foot of the perpendicular. (A hyperbola is called rectangular if its asymptotes are perpendicular.)

622. Find a transformation of the plane that maps the unit circle $x^2 + y^2 = 1$ into a cardioid. (Recall that the general equation of a cardioid is $r = 2a(1 + \cos\theta)$.)

623. Prove that the locus described by the equation $x^3 + 3xy + y^3 = 1$ contains precisely three noncollinear points A, B, C, equidistant to one another, and find the area of triangle ABC.

624. For n and p two positive integers consider the curve described by the parametric equations

$$x = a_1t^n + b_1t^p + c_1,$$
$$y = a_2t^n + b_2t^p + c_2,$$
$$z = a_3t^n + b_3t^p + c_3,$$

where t is a parameter. Prove that the curve is planar.

625. What is the equation that describes the shape of a hanging flexible chain with ends supported at the same height and acted on by its own weight?

4.1.4 Coordinate Geometry in Three and More Dimensions

In this section we emphasize quadrics. A quadric is a surface in space determined by a quadratic equation. The degenerate quadrics — linear varieties, cones, or cylinders over conics — add little to the picture from their two-dimensional counterparts, so we skip them. The nondegenerate quadrics are classified, up to an affine change of coordinates, as

$x^2 + y^2 + z^2 = 1$, ellipsoid;

$x^2 + y^2 - z^2 = 1$, hyperboloid of one sheet;

$x^2 - y^2 - z^2 = 1$, hyperboloid of two sheets;

$x^2 + y^2 = z$, elliptic paraboloid;

$x^2 - y^2 = z$, hyperbolic paraboloid.

In Cartesian coordinates, in these formulas there is a scaling factor in front of each term. For example, the standard form of an ellipsoid in Cartesian coordinates is

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1.$$

As in the case of conics, the equation of the tangent plane to a quadric at a point (x_0, y_0, z_0) is obtained by replacing in the equation of the quadric x^2, y^2, and z^2, respectively, by xx_0, yy_0, and zz_0; xy, xz, and yz, respectively, by $\frac{xy_0+yx_0}{2}$, $\frac{xz_0+zx_0}{2}$, and $\frac{yz_0+zy_0}{2}$; and x, y, and z in the linear terms, respectively, by $\frac{x+x_0}{2}$, $\frac{y+y_0}{2}$, and $\frac{z+z_0}{2}$.

Our first example comes from the 6th W.L. Putnam Mathematical Competition.

Example. Find the smallest volume bounded by the coordinate planes and by a tangent plane to the ellipsoid

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1.$$

Solution. The tangent plane to the ellipsoid at (x_0, y_0, z_0) has the equation

$$\frac{xx_0}{a^2} + \frac{yy_0}{b^2} + \frac{zz_0}{c^2} = 1.$$

Its x, y, and z intercepts are, respectively, $\frac{a^2}{x_0}$, $\frac{b^2}{y_0}$, and $\frac{c^2}{z_0}$. The volume of the solid cut off by the tangent plane and the coordinate planes is therefore

$$V = \frac{1}{6} \frac{a^2b^2c^2}{x_0y_0z_0} .$$

We want to minimize this with the constraint that (x_0, y_0, z_0) lie on the ellipsoid. This amounts to maximizing the function $f(x, y, z) = xyz$ with the constraint

$$g(x, y, z) = \frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1.$$

Because the ellipsoid is a closed bounded set, f has a maximum and a minimum on it. The maximum is positive, and the minimum is negative. The method of Lagrange multipliers yields the following system of equations in the unknowns x, y, z, and λ:

$$yz = 2 \ \frac{x}{a^2},$$
$$xz = 2 \ \frac{y}{b^2},$$
$$yz = 2 \ \frac{z}{c^2},$$
$$\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1.$$

Multiplying the first equation by x, the second by y, and the third by z, then summing up the three equations gives

$$3xyz = 2 \quad \frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} \quad = 2 \ .$$

Hence $\ = \frac{3}{2}xyz$. Then multiplying the first three equations of the system together, we obtain

$$(xyz)^2 = 8 \ {}^3\frac{xyz}{a^2b^2c^2} = \frac{27(xyz)^4}{a^2b^2c^2}.$$

The solution $xyz = 0$ we exclude, since it does not yield a maximum or a minimum. Otherwise, $xyz = -\frac{abc}{\overline{27}}$. The equality with the plus sign is the maximum of f; the other is the minimum. Substituting in the formula for the volume, we find that the smallest volume is $\frac{\overline{3}}{2}abc$.

Example. Find the nature of the surface defined as the locus of the lines parallel to a given plane and intersecting two given skew lines, neither of which is parallel to the plane.

Solution. We will work in affine coordinates. Call the plane and the two skew lines l_1 and l_2. The x- and y-axes lie in and the z-axis is l_1. The x-axis passes through l_2 . The y-axis is chosen to make l_2 parallel to the yz-plane. Finally, the orientation and the units are such that l_2 is given by $x = 1$, $y = z$ (see Figure 29).

A line parallel to and intersecting l_1 and l_2 passes through $(1, s, s)$ and $(0, 0, s)$, where s is some real parameter playing the role of the height. Thus the locus consists of all points of the form $t(1, s, s) + (1 \quad t)(0, 0, s)$, where s and t are real parameters. The coordinates (X, Y, Z) of such a point satisfy $X = t$, $Y = ts$, $Z = s$. By elimination we obtain the equation $XZ = Y$, which is a hyperbolic paraboloid like the one from Figure 30. We stress once more that the type of a quadric is invariant under affine transformations.

A surface generated by a moving line is called a ruled surface. Ruled surfaces are easy to build in real life. This together with its structural resistance makes the hyperbolic paraboloid popular as a roof in modern architecture (see for example Felix Candela s roof

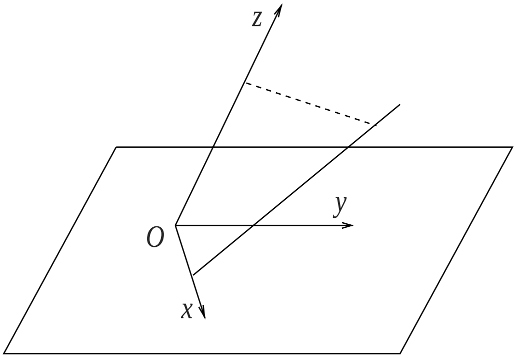

Figure 29

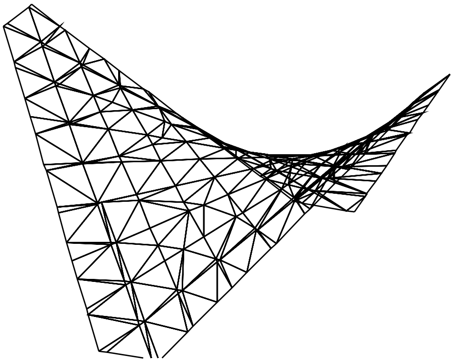

Figure 30

of the 1968 Olympic stadium in Mexico City). There is one more nondegenerate ruled quadric, which makes the object of the first problem in our list. And if you find some of the problems below too difficult, remember Winston Churchill s words: Success consists of going from failure to failure without loss of enthusiasm.

626. A cube is rotated about the main diagonal. What kind of surfaces do the edges describe?

627. Prove that the plane

$$\frac{x}{a}+\frac{y}{b}\quad\frac{z}{c}=1$$

is tangent to the hyperboloid of one sheet

$$\frac{x^2}{a^2}+\frac{y^2}{b^2}\quad\frac{z^2}{c^2}=1.$$

628. Through a point M on the ellipsoid

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1$$

take planes perpendicular to the axes Ox, Oy, Oz. Let the areas of the planar sections thus obtained be S_x, S_y, respectively, S_z. Prove that the sum

$$aS_x + bS_y + cS_z$$

is independent of M.

629. Determine the radius of the largest circle that can lie on the ellipsoid

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1 \quad (a > b > c).$$

630. Let a, b, c be distinct positive numbers. Prove that through each point of the three-dimensional space pass three surfaces described by equations of the form

$$\frac{x^2}{a^2 \qquad} + \frac{y^2}{b^2 \qquad} + \frac{z^2}{c^2 \qquad} = 1.$$

Determine the nature of these surfaces and prove that they are pairwise orthogonal along their curves of intersection.

631. Show that the equations

$$\begin{aligned} x &= u + v + w, \\ y &= u^2 + v^2 + w^2, \\ z &= u^3 + v^3 + w^3, \end{aligned}$$

where the parameters u, v, w are subject to the constraint $uvw = 1$, define a cubic surface.

We conclude our discussion of coordinate geometry with some problems in n dimensions.

Example. Through a fixed point inside an n-dimensional sphere, n mutually perpendicular chords are drawn. Prove that the sum of the squares of the lengths of the chords does not depend on their directions.

Solution. We want to prove that the sum in question depends only on the radius of the sphere and the distance from the fixed point to the center of the sphere. Choose a coordinate system in which the chords are the n orthogonal axes and the radius of the sphere is $R > 0$. The fixed point, which we call P, becomes the origin. The endpoints of each chord have only one nonzero coordinate, and in the appropriate ordering, the kth coordinates of the endpoints X_k and Y_k of the kth chord are the nonzero numbers x_k and y_k, $k = 1, 2, \ldots, n$. The center of the sphere is then

$$O = \left(\frac{x_1 + y_1}{2}, \frac{x_2 + y_2}{2}, \ldots, \frac{x_n + y_n}{2}\right).$$

The conditions that the points X_k and Y_k lie on the sphere can be written as

$$\left(x_k - \frac{x_k + y_k}{2}\right)^2 + \sum_{j \neq k}\left(\frac{x_j + y_j}{2}\right)^2 = R^2,$$
$$\left(y_k - \frac{x_k + y_k}{2}\right)^2 + \sum_{j \neq k}\left(\frac{x_j + y_j}{2}\right)^2 = R^2,$$

with $k = 1, 2, \ldots, n$. This implies

$$\left(\frac{x_k - y_k}{2}\right)^2 = R^2 - \sum_{j \neq k}\left(\frac{x_j + y_j}{2}\right)^2, \quad k = 1, 2, \ldots, n.$$

The term on the left is one-fourth of the square of the length of X_kY_k. Multiplying by 4 and summing up all these relations, we obtain

$$\sum_{k=1}^{n} \|X_kY_k\|^2 = 4nR^2 - 4\sum_{k=1}^{n}\sum_{j \neq k}\left(\frac{x_j + y_j}{2}\right)^2 = 4nR^2 - 4(n-1)\sum_{k=1}^{n}\left(\frac{x_k + y_k}{2}\right)^2$$
$$= 4nR^2 - 4(n-1)\|PO\|^2.$$

Hence the conclusion.

632. Let n be a positive integer. Prove that if the vertices of a $(2n+1)$-dimensional cube have integer coordinates, then the length of the edge of the cube is an integer.

633. For a positive integer n denote by τ the permutation cycle $(n, \ldots, 2, 1)$. Consider the locus of points in $\mathbb{R}^n$ defined by the equation

$$\sum_{\sigma} \operatorname{sign}(\sigma) x_{\sigma(1)} x_{\tau(\sigma(2))} \cdots x_{\tau^{n-1}(\sigma(n))} = 0,$$

where the sum is over all possible permutations of $\{1, 2, \ldots, n\}$. Prove that this locus contains a plane.

634. Prove that the intersection of an n-dimensional cube centered at the origin and with edges parallel to the coordinate axes with the plane determined by the vectors

$$a = \left(\cos\frac{2\pi}{n}, \cos\frac{4\pi}{n}, \ldots, \cos\frac{2n\pi}{n}\right) \quad \text{and} \quad b = \left(\sin\frac{2\pi}{n}, \sin\frac{4\pi}{n}, \ldots, \sin\frac{2n\pi}{n}\right)$$

is a regular $2n$-gon.

635. Find the maximum number of points on a sphere of radius 1 in $\mathbb{R}^n$ such that the distance between any two points is strictly greater than $\sqrt{2}$.

4.1.5 Integrals in Geometry

We now present various applications of integral calculus to geometry problems. Here is a classic.

Example. A disk of radius R is covered by m rectangular strips of width 2. Prove that $m \geq R$.

Solution. Since the strips have different areas, depending on the distance to the center of the disk, a proof using areas will not work. However, if we move to three dimensions the problem becomes easy. The argument is based on the following property of the sphere.

Lemma. *The area of the surface cut from a sphere of radius* R *by two parallel planes at distance* d *from each other is equal to* $2\pi Rd$.

To prove this result, let us assume that the sphere is centered at the origin and the planes are perpendicular to the x-axis. The surface is obtained by rotating the graph of the function $f : [a, b] \to \mathbb{R}$, $f(x) = \sqrt{R^2 - x^2}$ about the x-axis, where $[a, b]$ is an interval of length d. The area of the surface is given by

$$\begin{aligned} 2\pi \int_a^b f(x)\sqrt{(f'(x))^2 + 1}\,dx &= 2\pi \int_a^b \sqrt{R^2 - x^2}\,\frac{R}{\sqrt{R^2 - x^2}}\,dx \\ &= 2\pi \int_a^b R\,dx = 2\pi Rd. \end{aligned}$$

Returning to the problem, the sphere has area $4\pi R^2$ and is covered by m surfaces, each having area $4\pi R$. The inequality $4\pi mR \geq 4\pi R^2$ implies that $m \geq R$, as desired.

The second example, suggested to us by Zh. Wang, is even more famous. We present the proof from H. Solomon, *Geometric Probability* (SIAM 1978).

Crofton s theorem. *Let* D *be a bounded convex domain in the plane. Through each point* $P(x,y)$ *outside* D *there pass two tangents to* D. *Let* t_1 *and* t_2 *be the lengths of the segments determined by* P *and the tangency points, and let be the angle between the tangents, all viewed as functions of* (x,y).[1] *Then*

$$_{P/D}\ \frac{\sin}{t_1t_2}dxdy = 2\ {}^{2}.$$

Proof. The proof becomes transparent once we examine the particular case in which D is the unit disk $x^2+y^2 < 1$. Each point outside the unit disk can be parametrized by the pair of angles $(\ _1,\ _2)$ where the tangents meet the unit circle S^1. Since there is an ambiguity in which tangent is considered first, the outside of the disk is in 1-to-2 correspondence with the set $S^1 \times S^1$. It so happens, and we will prove it in general, that on changing coordinates from (x,y) to $(\ _1,\ _2)$, the integral from the statement becomes $^{++}\ d\ _1 d\ _2$ (divided by 2 to take the ambiguity into account). The result follows.

In the general case we mimic the same argument, boosting your intuition with Figure 31. Fix a Cartesian coordinate system with the origin O inside D. For a point (x,y) denote by $(\ _1,\ _2)$ the angles formed by the perpendiculars from O onto the tangents with the positive semiaxis. This is another parametrization of the exterior of D, again with the ambiguity of which tangent is considered first. Let $A_i(\ _i,\ _i)$, $i = 1,2$, be the tangency points.

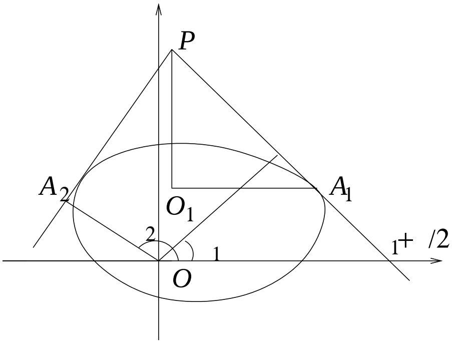

Figure 31

The main goal is to understand the change of coordinates $(x,y)\ \ (\ _1,\ _2)$ and in particular to write the Jacobian of this transformation. Writing the condition that the slope of the line A_1P is $\tan(\ _1 + \frac{}{2})$, we obtain

$$(x\ \ _1)\cos\ _1 + (y\ \ _1)\sin\ _1 = 0.$$

Taking the differential yields

---

[1] If the boundary of D has some edges, then there are points P for which t_1 and t_2 are not well defined, but the area of the set of these points is zero, so they can be neglected in the integral below.

$$\cos\ {}_1 dx \quad \cos\ {}_1 d\ {}_1 \quad (x \quad {}_1)\sin\ {}_1 d\ {}_1 + \sin\ {}_1 dy \quad \sin\ {}_1 d\ {}_1$$
$$+ (y \quad {}_1)\cos\ {}_1 d\ {}_1 = 0.$$

This expression can be simplified if we note that $\frac{d\ {}_1}{d\ {}_1}$ is the slope of the tangent, namely tan($_1$ + $\frac{}{2}$). Then cos $_1 d\ _1$ + sin $_1 d\ _1$ = 0, so

$$\cos\ {}_1 dx + \sin\ {}_1 dy = [(x \quad {}_1)\sin\ {}_1 \quad (y \quad {}_1)\cos\ {}_1] d\ {}_1.$$

And now a little Euclidean geometry. Consider the right triangle O_1A_1P with legs parallel to the axes. The altitude from O_1 determines on A_1P two segments of lengths $(x \quad {}_1)$ sin $_1$ and $(y \quad {}_1)$ cos $_1$ (you can see by examining the picture that the signs are right). This allows us to further transform the identity obtained above into

$$\cos\ {}_1 dx + \sin\ {}_1 dy = t_1 d\ {}_1.$$

The same argument shows that

$$\cos\ {}_2 dx + \sin\ {}_2 dy = t_2 d\ {}_2.$$

The Jacobian of the transformation is therefore the absolute value of

$$\frac{1}{t_1t_2}(\cos\ {}_1 \sin\ {}_2 \quad \sin\ {}_1 \cos\ {}_2) = \frac{1}{t_1t_2}\sin(\ {}_1 \quad {}_2).$$

And $_1$ $_2$ is, up to a sign, the supplement of . We obtain

$$2\ {}^2 = \frac{1}{2}\ {}_0^{2}\ {}_0^{2}\ d\ {}_1 d\ {}_2 = \ {}_{P/D} \frac{\sin}{t_1t_2} dxdy.$$

The theorem is proved.

636. A ring of height h is obtained by digging a cylindrical hole through the center of a sphere. Prove that the volume of the ring depends only on h and not on the radius of the sphere.

637. A polyhedron is circumscribed about a sphere. We call a face *big* if the projection of the sphere onto the plane of the face lies entirely within the face. Show that there are at most six big faces.

638. Let A and B be two finite sets of segments in three-dimensional space such that the sum of the lengths of the segments in A is larger than the sum of the lengths of the segments in B. Prove that there is a line in space with the property that the sum of the lengths of the projections of the segments in A onto that line is greater than the sum of the lengths of the projections of the segments in B.

639. Two convex polygons are placed one inside the other. Prove that the perimeter of the polygon that lies inside is smaller.

640. There are n line segments in the plane with the sum of the lengths equal to 1. Prove that there exists a straight line such that the sum of the lengths of the projections of the segments onto the line is equal to $\frac{2}{\ }$.

641. In a triangle ABC for a variable point P on BC with $PB = x$ let $t(x)$ be the measure of PAB. Compute

$$ {}_0^a \cos t(x)dx $$

in terms of the sides and angles of triangle ABC.

642. Let $f : [0, a] \quad R$ be a continuous and increasing function such that $f(0) = 0$. Define by R the region bounded by $f(x)$ and the lines $x = a$ and $y = 0$. Now consider the solid of revolution obtained when R is rotated around the y-axis as a sort of dish. Determine f such that the volume of water the dish can hold is equal to the volume of the dish itself, this happening for all a.

643. Consider a unit vector starting at the origin and pointing in the direction of the tangent vector to a continuously differentiable curve in three-dimensional space. The endpoint of the vector describes the spherical image of the curve (on the unit sphere). Show that if the curve is closed, then its spherical image intersects every great circle of the unit sphere.

644. With the hypothesis of the previous problem, if the curve is twice differentiable, then the length of the spherical image of the curve is called the total curvature. Prove that the total curvature of a closed curve is at least 2 .

645. A rectangle R is tiled by finitely many rectangles each of which has at least one side of integral length. Prove that R has at least one side of integral length.

4.1.6 Other Geometry Problems

We conclude with problems from elementary geometry. They are less in the spirit of Euclid, being based on algebraic or combinatorial considerations. Here imagination is more important than knowledge (A. Einstein).

Example. Find the maximal number of triangles of area 1 with disjoint interiors that can be included in a disk of radius 1. Describe all such configurations.

Solution. Let us first solve the following easier problem:

Find all triangles of area 1 *that can be placed inside a half-disk of radius* 1.

We will show that the only possible configuration is that in Figure 32. Consider a triangle that maximizes the area (such a triangle exists since the vertices vary on compact sets and the area depends continuously on the vertices). The vertices of this triangle must lie on the half-circle. If B lies between A and C, then A and C must be the endpoints of the diameter. Indeed, if say C is not an endpoint, then by moving it toward the closer endpoint of the diameter we increase both AC and the angle $\angle BAC$; hence we increase the area. Finally, among all triangles inscribed in a semicircle AC, the isosceles right triangle has maximal altitude, hence also maximal area. This triangle has area 1, and the claim is proved.

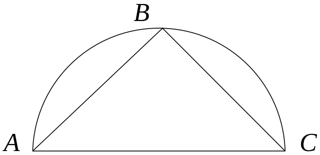

Figure 32

Returning to the problem, let us note that since the two triangles in question are convex sets, they can be separated by a line. That line cuts the disk into two regions, and one of them, containing one of the triangles, is included in a half-disk. By what we just proved, this region must itself be a half-disk. The only possible configuration consists of two isosceles triangles sharing the hypotenuse.

The next problem was published by the first author in the *Mathematics Magazine*.

Example. Let ABC be a right triangle ($\angle A = 90^\circ$). On the hypotenuse BC construct in the exterior the equilateral triangle BCD. Prove that the lengths of the segments AB, AC, and AD cannot all be rational.

Solution. We will find a relation between AB, AC, and AD by placing them in a triangle and using the law of cosines. For this, construct the equilateral triangle ACE in the exterior of ABC (Figure 33). We claim that $BE = AD$. This is a corollary of Napoleon's problem, and can be proved in the following way. Let M be the intersection of the circumcircles of BCD and ACE. Then $\angle AMC = 120^\circ$ and $\angle DMC = 60^\circ$; hence $M \in AD$. Similarly, $M \in BE$. Ptolemy's theorem applied to quadrilaterals $AMCE$ and $BMCD$ shows that $ME = AM + CM$ and $MD = BM + CM$; hence $AD = AM + BM + CM = BE$.

Applying the law of cosines in triangle ABE, we obtain $BE^2 = AB^2 + AE^2 + AB \cdot AE\sqrt{3}$, and since $BE = AD$ and $AE = AC$, it follows that

$$AD^2 = AB^2 + AC^2 + AB \cdot AC\sqrt{3}.$$

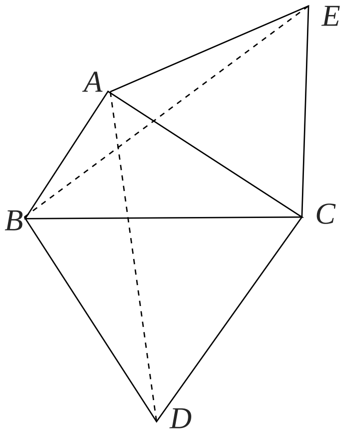

Figure 33

If all three segments AB, AC, and AD had rational lengths, this relation would imply that $\sqrt{3}$ is rational, which is not true. Hence at least one of these lengths is irrational.

646. Three lines passing through an interior point of a triangle and parallel to its sides determine three parallelograms and three triangles. If S is the area of the initial triangle and S_1, S_2, and S_3 are the areas of the newly formed triangles, prove that $S_1 + S_2 + S_3 \geq \frac{1}{3}S$.

647. Someone has drawn two squares of side 0.9 inside a disk of radius 1. Prove that the squares overlap.

648. A surface is generated by a segment whose midpoint rotates along the unit circle in the xy-plane such that for each $0 \leq \theta < 2\pi$, at the point of coordinates $(\cos\theta, \sin\theta)$ on the circle the segment is in the same plane with the z-axis and makes with it an angle of $\frac{\theta}{2}$. This surface, called a *Möbius band*, is depicted in Figure 34. What is the maximal length the segment can have so that the surface does not cross itself?

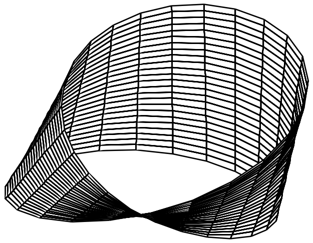

Figure 34

649. Let $ABCD$ be a convex quadrilateral and let O be the intersection of its diagonals. Given that the triangles OAB, OBC, OCD, and ODA have the same perimeter, prove that the quadrilateral is a rhombus. Does the property hold if O is some other point in the interior of the quadrilateral?

650. Prove that the plane cannot be covered by the interiors of finitely many parabolas.

651. Let ABC be a triangle with the largest angle at A. On line AB consider the point D such that A lies between B and D, and $AD = AB^3/AC^2$. Prove that $CD \leq \sqrt{3}BC^3/AC^2$.

652. Show that if all angles of an octagon are equal and all its sides have rational length, then the octagon has a center of symmetry.

653. Show that if each of the three main diagonals of a hexagon divides the hexagon into two parts with equal areas, then the three diagonals are concurrent.

654. Centered at every point with integer coordinates in the plane there is a disk with radius $\frac{1}{1000}$.
(a) Prove that there exists an equilateral triangle whose vertices lie in different disks.
(b) Prove that every equilateral triangle with vertices in different disks has side length greater than 96.

655. On a cylindrical surface of radius r, unbounded in both directions, consider n points and a surface S of area strictly less than 1. Prove that by rotating around the axis of the cylinder and then translating in the direction of the axis by at most $\frac{n}{4\pi r}$ units one can transform S into a surface that does not contain any of the n points.

4.2 Trigonometry

4.2.1 Trigonometric Identities

The beauty of trigonometry lies in its identities. There are two fundamental identities,

$$\sin^2 x + \cos^2 x = 1 \quad \text{and} \quad \cos(x \pm y) = \cos x \cos y \mp \sin x \sin y,$$

both with geometric origins, from which all the others can be derived. Our problems will make use of addition and subtraction formulas for two, three, even four angles, double- and triple-angle formulas, and product-to-sum formulas.

Example. Find all acute angles x satisfying the equation

$$2 \sin x \cos 40^\circ = \sin(x + 20^\circ).$$

Solution. Trying particular values we see that $x = 30^\circ$ is a solution. Are there other solutions? Use the addition formula for sine to rewrite the equation as

$$\tan x = \frac{\sin 20^\circ}{2\cos 40^\circ - \cos 20^\circ}.$$

The tangent function is one-to-one on the interval $(0, 90^\circ)$, which implies that the solution to the original equation is unique.

Example.

(a) Prove that if $\cos(\pi a) = \frac{1}{3}$ then a is an irrational number.
(b) Prove that a regular tetrahedron cannot be dissected into finitely many regular tetrahedra.

Solution. (a) Assume that a is rational, $a = \frac{m}{n}$. Then $\cos(n\pi a) = -1$. We will prove by induction that for all $k > 0$, $\cos(k\pi a) = \frac{m_k}{3^k}$, with m_k an integer that is not divisible by 3. This will then contradict the initial assumption.

The property is true for $k = 0$ and 1. The product-to-sum formula for cosines gives rise to the recurrence

$$\cos((k+1)\pi a) = 2\cos(\pi a)\cos(k\pi a) - \cos((k-1)\pi a), \quad k \geq 1.$$

Using the induction hypothesis, we obtain $\cos((k+1)\pi a) = \frac{m_{k+1}}{3^{k+1}}$, with $m_{k+1} = 2m_k - 3m_{k-1}$. Since m_k is not divisible by 3, neither is m_{k+1}, and the claim is proved.

Part (b) is just a consequence of (a). To see this, let us compute the cosine of the dihedral angle of two faces of a regular tetrahedron $ABCD$. If AH is an altitude of the tetrahedron and AE is an altitude of the face ABC, then $\angle AEH$ is the dihedral angle of the faces ABC and BCD (see Figure 35). In the right triangle HAE, $\cos\angle AEH = \frac{EH}{AD} = \frac{1}{3}$.

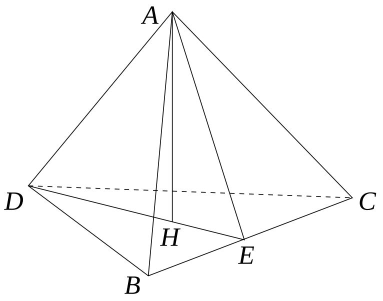

Figure 35

Now assume that there exists a dissection of a regular tetrahedron into regular tetrahedra. Several of these tetrahedra meet along a segment included in one of the faces of the initial tetrahedron. Their dihedral angles must add up to π, which implies that the dihedral angle of a regular tetrahedron is of the form $\frac{\pi}{n}$, for some integer n. This was shown above to be false. Hence no dissection of a regular tetrahedron into regular tetrahedra exists.

Remark. It is interesting to know that Leonardo da Vinci's manuscripts contain drawings of such decompositions. Later, however, Leonardo himself realized that the decompositions were impossible, and the drawings were mere optical illusions. Note also that Dehn's invariant mentioned in the first chapter provides an obstruction to the decomposition.

We conclude the introduction with a problem by the second author of the book.

Example. Let $a_0 = \sqrt{2} + \sqrt{3} + \sqrt{6}$ and let $a_{n+1} = \frac{a_n^2 - 5}{2(a_n+2)}$ for $n \geq 0$. Prove that

$$a_n = \cot\left(\frac{2^{n-3}\pi}{3}\right) - 2 \quad \text{for all } n.$$

Solution. We have

$$\cot\frac{\pi}{24} = \frac{\cos\frac{\pi}{24}}{\sin\frac{\pi}{24}} = \frac{2\cos^2\frac{\pi}{24}}{2\sin\frac{\pi}{24}\cos\frac{\pi}{24}} = \frac{1+\cos\frac{\pi}{12}}{\sin\frac{\pi}{12}} = \frac{1+\cos\left(\frac{\pi}{3}-\frac{\pi}{4}\right)}{\sin\left(\frac{\pi}{3}-\frac{\pi}{4}\right)}.$$

Using the subtraction formulas for sine and cosine we find that this is equal to

$$\frac{1+\frac{\sqrt{2}}{4}+\frac{\sqrt{6}}{4}}{\frac{\sqrt{6}}{4}-\frac{\sqrt{2}}{4}} = \frac{4+\sqrt{6}+\sqrt{2}}{\sqrt{6}-\sqrt{2}} = \frac{4(\sqrt{6}+\sqrt{2})+(\sqrt{6}+\sqrt{2})^2}{6-2}$$

$$= \frac{4(\sqrt{6}+\sqrt{2})+8+4\sqrt{3}}{4} = 2+\sqrt{2}+\sqrt{3}+\sqrt{6} = a_0+2.$$

Hence the equality $a_n = \cot\left(\frac{2^{n-3}\pi}{3}\right) - 2$ is true at least for $n = 0$.

To verify it in general, it suffices to prove that $b_n = \cot\left(\frac{2^{n-3}\pi}{3}\right)$, where $b_n = a_n + 2$, $n \geq 1$. The recurrence relation becomes

$$b_{n+1} - 2 = \frac{(b_n - 2)^2 - 5}{2b_n},$$

or $b_{n+1} = \frac{b_n^2 - 1}{2b_n}$. Assuming inductively that $b_k = \cot c_k$, where $c_k = \frac{2^{k-3}\pi}{3}$, and using the double-angle formula, we obtain

$$b_{k+1} = \frac{\cot^2 c_k - 1}{2\cot c_k} = \cot(2c_k) = \cot c_{k+1}.$$

This completes the proof.

656. Prove that

$$\sin 70^\circ \cos 50^\circ + \sin 260^\circ \cos 280^\circ = \frac{\sqrt{3}}{4}.$$

657. Show that the trigonometric equation

$$\sin(\cos x) = \cos(\sin x)$$

has no solutions.

658. Show that if the angles a and b satisfy

$$\tan^2 a \tan^2 b = 1 + \tan^2 a + \tan^2 b,$$

then

$$\sin a \sin b = - \sin 45\ .$$

659. Find the range of the function $f : R \quad\quad R$, $f(x) = (\sin x + 1)(\cos x + 1)$.

660. Prove that

$$\sec^{2n} x + \csc^{2n} x \quad\quad 2^{n+1},$$

for all integers $n \quad\quad 0$, and for all $x \quad\quad (0, \frac{}{2})$.

661. Compute the integral

$$\overline{\frac{1 \quad x}{1 + x}} dx, \quad\quad x \quad\quad (\quad 1, 1).$$

662. Find all integers k for which the two-variable function $f(x, y) = \cos(19x + 99y)$ can be written as a polynomial in $\cos x, \cos y, \cos(x + ky)$.

663. Let $a, b, c, d \quad\quad [0, \quad]$ be such that

$$2\cos a + 6\cos b + 7\cos c + 9\cos d = 0$$

and

$$2\sin a \quad\quad 6\sin b + 7\sin c \quad\quad 9\sin d = 0.$$

Prove that $3\cos(a + d) = 7\cos(b + c)$.

664. Let a be a real number. Prove that

$$5(\sin^3 a + \cos^3 a) + 3\sin a \cos a = 0.04$$

if and only if

$$5(\sin a + \cos a) + 2\sin a \cos a = 0.04.$$

665. Let $a_0, a_1, \ldots, a_n$ be numbers from the interval $(0, \frac{}{2})$ such that

$$\tan \quad a_0 \quad \frac{}{4} \quad + \tan \quad a_1 \quad \frac{}{4} \quad + \cdots + \tan \quad a_n \quad \frac{}{4} \quad\quad n \quad 1.$$

Prove that

$$\tan a_0 \tan a_1 \cdots \tan a_n \quad\quad n^{n+1}.$$

4.2.2 Euler's Formula

For a complex number z,

$$e^z = 1 + \frac{z}{1!} + \frac{z^2}{2!} + \cdots + \frac{z^n}{n!} + \cdots .$$

In particular, for an angle x,

$$e^{ix} = 1 + i\frac{x}{1!} - \frac{x^2}{2!} - i\frac{x^3}{3!} + \frac{x^4}{4!} + i\frac{x^5}{5!} - \frac{x^6}{6!} - i\frac{x^7}{7!} + \cdots .$$

The real part of e^{ix} is

$$1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \cdots ,$$

while the imaginary part is

$$\frac{x}{1!} - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \cdots .$$

These are the Taylor series of $\cos x$ and $\sin x$. We obtain Euler's formula

$$e^{ix} = \cos x + i \sin x.$$

Euler's formula gives rise to one of the most beautiful identities in mathematics: $e^{i\pi} = -1$, which relates the number e from real analysis, the imaginary unit i from algebra, and π from geometry.

The equality $e^{nz} = (e^z)^n$ holds at least for z a real number. Two power series are equal for all real numbers if and only if they are equal coefficient by coefficient (since coefficients are computed using the derivatives at 0). So equality for real numbers means equality for complex numbers. In particular, $e^{inx} = (e^{ix})^n$, from which we deduce the de Moivre formula

$$\cos nx + i \sin nx = (\cos x + i \sin x)^n.$$

We present an application of the de Moivre formula that we found in *Exercises and Problems in Algebra* by C. Nastasescu, C. Niţa, M. Brandiburu, and D. Joiţa (Editura Didactica şi Pedagogica, Bucharest, 1983).

Example. Prove the identity

$$\binom{n}{0} + \binom{n}{k} + \binom{n}{2k} + \cdots = \frac{2^n}{k}\sum_{j=1}^{k} \cos^n \frac{j\pi}{k} \cos \frac{nj\pi}{k}.$$

Solution. Let $\epsilon_1, \epsilon_2, \dots, \epsilon_k$ be the kth roots of unity, that is, $\epsilon_j = \cos\frac{2j\pi}{k} + i\sin\frac{2j\pi}{k}$, $j = 1, 2, \dots, k$. The sum

$$\epsilon_1^s + \epsilon_2^s + \cdots + \epsilon_k^s$$

is equal to k if k divides s, and to 0 if k does not divide s. We have

$$\sum_{j=1}^{k} (1 + \epsilon_j)^n = \sum_{s=0}^{n} \binom{n}{s} \sum_{j=1}^{k} \epsilon_j^s = k \sum_{j=0}^{\lfloor \frac{n}{k} \rfloor} \binom{n}{jk}.$$

Since

$$1 + \epsilon_j = 2\cos\frac{j\pi}{k}\left(\cos\frac{j\pi}{k} + i\sin\frac{j\pi}{k}\right),$$

it follows from the de Moivre formula that

$$\sum_{j=1}^{k} (1 + \epsilon_j)^n = \sum_{j=1}^{k} 2^n \cos^n\frac{j\pi}{k}\left(\cos\frac{nj\pi}{k} + i\sin\frac{nj\pi}{k}\right).$$

Therefore,

$$\binom{n}{0} + \binom{n}{k} + \binom{n}{2k} + \cdots = \frac{2^n}{k}\sum_{j=1}^{k} \cos^n\frac{j\pi}{k}\left(\cos\frac{nj\pi}{k} + i\sin\frac{nj\pi}{k}\right).$$

The left-hand side is real, so we can ignore the imaginary part and obtain the identity from the statement.

And now a problem given at an Indian Team Selection Test for the International Mathematical Olympiad in 2005, proposed by the first author of the book.

Example. For real numbers a, b, c, d not all equal to zero, let $f : \mathbb{R} \to \mathbb{R}$,

$$f(x) = a + b\cos 2x + c\sin 5x + d\cos 8x.$$

Suppose that $f(t) = 4a$ for some real number t. Prove that there exists a real number s such that $f(s) < 0$.

Solution. Let $g(x) = be^{2ix} - ice^{5ix} + de^{8ix}$. Then $f(x) = a + \operatorname{Re} g(x)$. Note that

$$g(x) + g\left(x + \frac{2\pi}{3}\right) + g\left(x + \frac{4\pi}{3}\right) = g(x)\left(1 + e^{2\pi i/3} + e^{4\pi i/3}\right) = 0.$$

Therefore,

$$f(x) + f \quad x + \frac{2}{3} \quad + f \quad x + \frac{4}{3} \quad = 3a.$$

If $a < 0$, then $s = t$ would work. If $a = 0$, then for some x one of the terms of the above sum is negative. This is because $f(x)$ is not identically zero, since its Fourier series is not trivial. If $a > 0$, substituting $x = t$ in the identity deduced above and using the fact that $f(t) = 4a$, we obtain

$$f \quad t + \frac{2}{3} \quad + f \quad t + \frac{4}{3} \quad = \quad a < 0.$$

Hence either $f(t + \frac{2}{3})$ or $f(t + \frac{4}{3})$ is negative. The problem is solved.

666. Prove the identity

$$\frac{1 + i \tan t}{1 \quad i \tan t}^{\,n} = \frac{1 + i \tan nt}{1 \quad i \tan nt}, \quad n \quad 1.$$

667. Prove the identity

$$1 \quad \genfrac{}{}{0pt}{}{n}{2} + \genfrac{}{}{0pt}{}{n}{4} \quad \genfrac{}{}{0pt}{}{n}{6} + \cdots = 2^{n/2} \cos \frac{n}{4}, \quad n \quad 1.$$

668. Compute the sum

$$\genfrac{}{}{0pt}{}{n}{1} \cos x + \genfrac{}{}{0pt}{}{n}{2} \cos 2x + \cdots + \genfrac{}{}{0pt}{}{n}{n} \cos nx.$$

669. Find the Taylor series expansion at 0 of the function

$$f(x) = e^{x \cos} \quad \cos(x \sin \quad),$$

where is a parameter.

670. Let z_1, z_2, z_3 be complex numbers of the same absolute value, none of which is real and all distinct. Prove that if $z_1 + z_2z_3$, $z_2 + z_3z_1$ and $z_3 + z_1z_2$ are all real, then $z_1z_2z_3 = 1$.

671. Let n be an odd positive integer and let be a real number such that − is irrational. Set $a_k = \tan(\quad + \frac{k}{n})$, $k = 1, 2, \ldots, n$. Prove that

$$\frac{a_1 + a_2 + \cdots + a_n}{a_1a_2 \cdots a_n}$$

is an integer and determine its value.

672. Find $(\cos \quad)(\cos 2 \quad)(\cos 3 \quad) \cdots (\cos 999 \quad)$ with $\quad = \frac{2}{1999}$.

673. For positive integers n define $F(n) = x^n \sin(nA) + y^n \sin(nB) + z^n \sin(nC)$, where x, y, z, A, B, C are real numbers and $A + B + C = k\pi$ for some integer k. Prove that if $F(1) = F(2) = 0$, then $F(n) = 0$ for all positive integers n.

674. The continuous real-valued function $\varphi(t)$ is defined for $t \geq 0$ and is absolutely integrable on every bounded interval. Define

$$P = \int_0^\infty e^{-(t+i\varphi(t))}dt \quad \text{and} \quad Q = \int_0^\infty e^{-2(t+i\varphi(t))}dt.$$

Prove that

$$|4P^2 - 2Q| \leq 3,$$

with equality if and only if $\varphi(t)$ is constant.

4.2.3 Trigonometric Substitutions

The fact that the circle $x^2 + y^2 = 1$ can be parametrized by trigonometric functions as $x = \cos t$ and $y = \sin t$ gives rise to the standard substitution $x = a\cos t$ (or $x = a\sin t$) in expressions of the form $\sqrt{a^2 - x^2}$. Our purpose is to emphasize less standard substitutions, usually suggested by the similarity between an algebraic expression and a trigonometric formula. Such is the case with the following problem from the 61st W.L. Putnam Mathematical Competition, 2000.

Example. Let $f : [-1, 1] \to \mathbb{R}$ be a continuous function such that $f(2x^2 - 1) = 2xf(x)$ for all $x \in [-1, 1]$. Show that f is identically equal to zero.

Solution. Here the expression $2x^2 - 1$ should remind us of the trigonometric formula $2\cos^2 t - 1 = \cos 2t$, suggesting the substitution $x = \cos t$, $t \in [0, \pi]$. The functional equation from the statement becomes $f(\cos 2t) = 2\cos t f(\cos t)$.

First, note that setting $x = 0$ and $x = 1$, we obtain $f(1) = f(-1) = 0$. Now let us define $g : \mathbb{R} \to \mathbb{R}$, $g(t) = \frac{f(\cos t)}{\sin t}$. Then for any t not a multiple of π,

$$g(2t) = \frac{f(2\cos^2 t - 1)}{\sin(2t)} = \frac{2\cos t f(\cos t)}{2\sin t\cos t} = \frac{f(\cos t)}{\sin t} = g(t).$$

Also, $g(t + 2\pi) = g(t)$. In particular, for any integers n and k,

$$g\left(1 + \frac{n\pi}{2^k}\right) = g(2^{k+1} + 2n\pi) = g(2^{k+1}) = g(1).$$

Because f is continuous, g is continuous everywhere except at multiples of π. The set $\{1 + \frac{n\pi}{2^k} \mid n, k \in \mathbf{Z}\}$ is dense on the real axis, and so g must be constant on its domain.

Then $f(\cos t) = c\sin t$ for some constant c and t in $(0, \pi)$, i.e., $f(x) = c\sqrt{1 - x^2}$ for all $x \in (-1, 1)$. It follows that f is an even function. But then in the equation from the statement $f(2x^2 - 1) = 2xf(x)$ the left-hand side is an even function while the right-hand side is an odd function. This can happen only if both sides are identically zero. Therefore, $f(x) = 0$ for $x \in [-1, 1]$ is the only solution to the functional equation.

We continue with a problem that was proposed by Belgium for the 26th International Mathematical Olympiad in 1985.

Example. Let x, y, z be real numbers such that $x + y + z = xyz$. Prove that

$$x(1 - y^2)(1 - z^2) + y(1 - z^2)(1 - x^2) + z(1 - x^2)(1 - y^2) = 4xyz.$$

Solution. The conclusion is immediate if $xyz = 0$, so we may assume that $x, y, z \neq 0$. Dividing through by $4xyz$ we transform the desired equality into

$$\frac{1 - y^2}{2y} \cdot \frac{1 - z^2}{2z} + \frac{1 - z^2}{2x} \cdot \frac{1 - x^2}{2x} + \frac{1 - x^2}{2x} \cdot \frac{1 - y^2}{2y} = 1.$$

This, along with the condition from the statement, makes us think about the substitutions $x = \tan A$, $y = \tan B$, $z = \tan C$, where A, B, C are the angles of a triangle. Using the double-angle formula

$$\frac{1 - \tan^2 u}{2\tan u} = \frac{1}{\tan 2u} = \cot 2u$$

we further transform the equality into

$$\cot 2B \cot 2C + \cot 2C \cot 2A + \cot 2A \cot 2B = 1.$$

But this is equivalent to

$$\tan 2A + \tan 2B + \tan 2C = \tan 2A \tan 2B \tan 2C,$$

which follows from $\tan(2A + 2B + 2C) = \tan 2\pi = 0$.

And now the problems.

675. Let $a, b, c \in [0, 1]$. Prove that

$$\sqrt{abc} + \sqrt{(1 - a)(1 - b)(1 - c)} \leq 1.$$

676. Solve the equation $x^3 - 3x = \sqrt{x + 2}$ in real numbers.

677. Find the maximum value of

$$S = (1 \quad x_1)(1 \quad y_1) + (1 \quad x_2)(1 \quad y_2)$$

if $x_1^2 + x_2^2 = y_1^2 + y_2^2 = c^2$, where c is some positive number.

678. Prove for all real numbers a, b, c the inequality

$$\frac{|a \quad b|}{\overline{1 + a^2}\ \ \overline{1 + b^2}} \qquad \frac{|a \quad c|}{\overline{1 + a^2}\ \ \overline{1 + c^2}} + \frac{|b \quad c|}{\overline{1 + b^2}\ \ \overline{1 + c^2}}.$$

679. Let a, b, c be real numbers. Prove that

$$(ab + bc + ca \quad 1)^2 \quad (a^2 + 1)(b^2 + 1)(c^2 + 1).$$

680. Prove that

$$\frac{x}{\overline{1 + x^2}} + \frac{y}{\overline{1 + y^2}} + \frac{z}{\overline{1 + z^2}} \qquad \frac{3\ \overline{3}}{2}$$

if the positive real numbers x, y, z satisfy $x + y + z = xyz$.

681. Prove that

$$\frac{x}{1 \quad x^2} + \frac{y}{1 \quad y^2} + \frac{z}{1 \quad z^2} \qquad \frac{3\ \overline{3}}{2}$$

if $0 < x, y, z < 1$ and $xy + yz + xz = 1$.

682. Solve the following system of equations in real numbers:

$$\frac{3x \quad y}{x \quad 3y} = x^2,$$
$$\frac{3y \quad z}{y \quad 3z} = y^2,$$
$$\frac{3z \quad x}{z \quad 3x} = z^2.$$

683. Let $a_0 = \quad \overline{2}$, $b_0 = 2$, and

$$a_{n+1} = \overline{2 \qquad \overline{4 \quad a_n^2}}, \qquad b_{n+1} = \frac{2b_n}{2 + \quad \overline{4 + b_n^2}}, \qquad n \quad 0.$$

(a) Prove that the sequences $(a_n)_n$ and $(b_n)_n$ are decreasing and converge to zero.

(b) Prove that the sequence $(2^n a_n)_n$ is increasing, the sequence $(2^n b_n)_n$ is decreasing, and these two sequences converge to the same limit.

(c) Prove there is a positive constant C such that one has $0 < b_n - a_n < \frac{C}{8^n}$ for all n.

684. Two real sequences $x_1, x_2, \ldots$, and $y_1, y_2, \ldots$ are defined in the following way:

$$x_1 = y_1 = \sqrt{3}, \quad x_{n+1} = x_n + \sqrt{1 + x_n^2}, \quad y_{n+1} = \frac{y_n}{1 + \sqrt{1 + y_n^2}}, \quad \text{for } n \geq 1.$$

Prove that $2 < x_n y_n < 3$ for all $n > 1$.

685. Let a, b, c be real numbers different from $-\frac{1}{\sqrt{3}}$. Prove that the equality $abc = a + b + c$ holds only if

$$\frac{3a - a^3}{3a^2 - 1} \cdot \frac{3b - b^3}{3b^2 - 1} \cdot \frac{3c - c^3}{3c^2 - 1} = \frac{3a - a^3}{3a^2 - 1} + \frac{3b - b^3}{3b^2 - 1} + \frac{3c - c^3}{3c^2 - 1}.$$

The parametrization of the hyperbola $x^2 - y^2 = 1$ by $x = \cosh t$, $y = \sinh t$ gives rise to the hyperbolic substitution $x = a \cosh t$ in expressions containing $\sqrt{a^2 - 1}$. We illustrate this with an example by the second author.

Example. Let $a_1 = a_2 = 97$ and

$$a_{n+1} = a_n a_{n-1} + \sqrt{(a_n^2 - 1)(a_{n-1}^2 - 1)}, \quad \text{for } n > 1.$$

Prove that

(a) $2 + 2a_n$ is a perfect square;
(b) $2 + \sqrt{2 + 2a_n}$ is a perfect square.

Solution. We are led to the substitution $a_n = \cosh t_n$ for some number t_n (which for the moment might be complex). The recurrence relation becomes

$$\cosh t_{n+1} = a_{n+1} = \cosh t_n \cosh t_{n-1} + \sinh t_n \sinh t_{n-1} = \cosh(t_n + t_{n-1}).$$

We deduce that the numbers t_n satisfy $t_0 = t_1$, and $t_{n+1} = t_n + t_{n-1}$ (in particular they are all real). And so $t_n = F_n t_0$, where $(F_n)_n$ is the Fibonacci sequence. Consequently, $a_n = \cosh(F_n t_0)$, $n \geq 1$.

Using the identity $2(\cosh t)^2 - 1 = \cosh 2t$, we obtain

$$2 + 2a_n = \left(2 \cosh F_n \frac{t_0}{2}\right)^2.$$

The recurrence relation

$$2 \cosh(k + 1)t = (2 \cosh t)(2 \cosh kt) - 2 \cosh(k - 1)t$$

allows us to prove inductively that $2\cosh k\frac{t_0}{2}$ is an integer once we show that $2\cosh\frac{t_0}{2}$ is an integer. It would then follow that $2\cosh F_n\frac{t_0}{2}$ is an integer as well. And indeed $2\cosh\frac{t_0}{2} = \sqrt{2+2a_1} = 14$. This completes the proof of part (a).

To prove (b), we obtain in the same manner

$$2+\sqrt{2+2a_n} = \left(2\cosh F_n\frac{t_0}{4}\right)^2,$$

and again we have to prove that $2\cosh\frac{t_0}{4}$ is an integer. We compute $2\cosh\frac{t_0}{4} = \sqrt{2+\sqrt{2+2a_n}} = \sqrt{2+14} = 4$. The conclusion follows.

686. Compute the integral

$$\int \frac{dx}{x+\sqrt{x^2-1}}.$$

687. Let $n > 1$ be an integer. Prove that there is no irrational number a such that the number

$$\sqrt[n]{a+\sqrt{a^2-1}}+\sqrt[n]{a-\sqrt{a^2-1}}$$

is rational.

4.2.4 Telescopic Sums and Products in Trigonometry

The philosophy of telescopic sums and products in trigonometry is the same as in the general case, just that here we have more identities at hand. Let us take a look at a slightly modified version of an identity of C.A. Laisant.

Example. Prove that

$$\sum_{k=0}^{n}\left(-\frac{1}{3}\right)^k\cos^3\left(3^{k-n}\pi\right) = \frac{3}{4}\left[\left(-\frac{1}{3}\right)^{n+1}+\cos\frac{\pi}{3^n}\right].$$

Solution. From the identity $\cos 3x = 4\cos^3 x - 3\cos x$, we obtain

$$\cos^3 x = \frac{1}{4}(\cos 3x + 3\cos x).$$

Then

$$\sum_{k=0}^{n}\left(-\frac{1}{3}\right)^k\cos^3\left(3^k a\right) = \frac{1}{4}\sum_{k=0}^{n}\left[\left(-\frac{1}{3}\right)^k\cos\left(3^{k+1}a\right)-\left(-\frac{1}{3}\right)^{k-1}\cos\left(3^k a\right)\right].$$

This telescopes to

$$\overset{2}{\frac{1}{4}}\qquad \frac{1}{3}^{\;n}\cos\ 3^{n+1}a \qquad\qquad \frac{1}{3}^{\;1}\overset{3}{\cos a}\ \ .$$

For $a = 3\ ^{n}$, we obtain the identity from the statement.

Test your skills against the following problems.

688. Prove that

$$27\sin^3 9\ \ + 9\sin^3 27\ \ + 3\sin^3 81\ \ + \sin^3 243\ \ = 20\sin 9\ \ .$$

689. Prove that

$$\frac{1}{\cot 9\qquad 3\tan 9} + \frac{3}{\cot 27\qquad 3\tan 27} + \frac{9}{\cot 81\qquad 3\tan 81} + \frac{27}{\cot 243\qquad 3\tan 243} = 10\tan 9\ \ .$$

690. Prove that

$$\frac{1}{\sin 45\ \ \sin 46} + \frac{1}{\sin 47\ \ \sin 48} + \cdots + \frac{1}{\sin 133\ \ \sin 134} = \frac{1}{\sin 1}.$$

691. Obtain explicit values for the following series:

(a) $\displaystyle \underset{n=1}{\quad}\ \arctan\frac{2}{n^2},$

(b) $\displaystyle \underset{n=1}{\quad}\ \arctan\frac{8n}{n^4\qquad 2n^2+5}.$

692. For $n\quad 0$ let

$$u_n = \arcsin\frac{\overline{n+1}\qquad \overline{n}}{\overline{n+2}\ \ \overline{n+1}}.$$

Prove that the series

$$S = u_0 + u_1 + u_2 + \cdots + u_n + \cdots$$

is convergent and find its limit.

Now we turn to telescopic products.

Example. Prove that

$$\,_{n=1}\frac{1}{1 \quad \tan^2 2^{\quad n}} = \tan 1.$$

Solution. The solution is based on the identity

$$\tan 2x = \frac{2\tan x}{1 \quad \tan^2 x}.$$

Using it we can write

$$\,_{n=1}^{N}\frac{1}{1 \quad \tan^2 2^{\quad n}} = \,_{n=1}^{N}\frac{\tan 2^{\quad n+1}}{2\tan 2^{\quad n}} = \frac{2^{\quad N}}{\tan 2^{\quad N}}\tan 1.$$

Since $\lim_{x \quad 0}\frac{\tan x}{x} = 1$, when letting N this becomes tan 1, as desired.

693. In a circle of radius 1 a square is inscribed. A circle is inscribed in the square and then a regular octagon in the circle. The procedure continues, doubling each time the number of sides of the polygon. Find the limit of the lengths of the radii of the circles.

694. Prove that

$$1 \quad \frac{\cos 61}{\cos 1} \quad 1 \quad \frac{\cos 62}{\cos 2} \quad \cdots \quad 1 \quad \frac{\cos 119}{\cos 59} = 1.$$

695. Evaluate the product

$$(1 \quad \cot 1\ )(1 \quad \cot 2\ )\cdots(1 \quad \cot 44\ ).$$

696. Compute the product

$$(\ \overline{3} + \tan 1\ )(\ \overline{3} + \tan 2\ )\cdots(\ \overline{3} + \tan 29\ ).$$

697. Prove the identities

(a) $\frac{1}{2} \quad \cos\frac{}{7} \quad \frac{1}{2} \quad \cos\frac{3}{7} \quad \frac{1}{2} \quad \cos\frac{9}{7} = \frac{1}{8},$

(b) $\frac{1}{2} + \cos\frac{}{20} \quad \frac{1}{2} + \cos\frac{3}{20} \quad \frac{1}{2} + \cos\frac{9}{20} \quad \frac{1}{2} + \cos\frac{27}{20} = \frac{1}{16}.$

698. Prove the identities

(a) $\,_{n=1}^{24} \sec(2^n) = 2^{24}\tan 2\ ,$

(b) $\,_{n=2}^{25} (2\cos(2^n) \quad \sec(2^n)\ ) = \quad 1.$

11.3 OMEGA TRIANGLES

Johann Friedrich Carl Gauss was born on April 30, 1777 in Brunswick in the German Duchy of Brunswick-Wolfenbüttel. He was born into a poor family. His paternal grandparents were originally small farmers but moved to Brunswick around 1740 in search of a better life. Gauss' parents, Gebhard and Dorothea, were hardworking but not well educated. Gebhard found that the local guilds did not welcome outsiders, so he struggled to find work. He would move from job to job, sometimes working as a gardener, a canal worker, a butcher, and sometimes as an accountant. This brought the family steady income, but acquiring wealth was very slow. This meant that the family goal of owning a home would take many years, but once achieved it would be a significant step up in social status (Bühler 1981, 5–6, 8; Burton 1985, 509–510).

After surviving a near drowning when he was around the age of 3, Gauss entered elementary school in 1784. In a class of about 50 students of various ages and abilities, Gauss stood out. He already knew how to read and write upon enrolling, abilities that he had taught himself. Supposedly, when he was 3 he could count and perform simple calculations, even to the point of correcting his father's ledgers. His masters at the school, J. G. Büttner and his assistant Martin Bartels, soon realized that they had an exceptional student on their hands. The details of the story differ among the various reports, but the essentials are that one day Gauss's class was given the task of adding the numbers from 1 to 100, either as simple busywork or as a punishment. Within moments Gauss had the answer, and it was the only correct one in the class! He had simply recognized the pattern in the sequence

$$1, 2, 3, \ldots, 98, 99, 100.$$

Since there are 50 pairs of numbers that add to 101, the sum must be 5050. Fortunately for the young Gauss, both Büttner and Bartels were good teachers, and they encouraged him in his studies. It was Büttner who aided Gauss in enrolling in secondary school in 1788. Gauss definitely benefited from his new surroundings. Not only was his academic life more structured, but he greatly improved his language skills. Up until this point, Gauss spoke only the local dialect of Brunswick. In secondary school he not only learned High German but also Latin (Bühler 1981, 7; Burton 1985, 510).

In 1791 an event happened to Gauss that would open more academic doors. Because of his excellent work in school, he was introduced to Duke Ferdinand of Brunswick. The duke was impressed with Gauss's achievements in school. As he had done with other promising students, Ferdinand granted Gauss the financial backing that would enable him to continue his education. This support was in the form of a stipend and would continue for many years. It eventually enabled Gauss to earn a doctorate and gave him the freedom to pursue some of his early mathematical research. Such backing was crucial for someone from his social standing at this time in Germany (Bühler 1981, 8; Burton 1985, 510).

The next stop in Gauss's academic career was Caroline College in 1792. He studied there until he was 18. This was a relatively new school, just 10 years old. Its curriculum was focused on the sciences, and it had a very good library. In it

Gauss found most of the great and contemporary works in mathematics. He studied the works of Newton and Archimedes, his two favorite mathematicians. It may have been in this library where Gauss began his work on the Parallel Postulate. As with many before him, he attempted to prove it indirectly, and as with many before him, his results were surprising but not contradictory. He would pursue this subject occasionally throughout the rest of his life (Bühler 1981, 8–9; Bonola 1912, 65).

Thus far, Gauss's education was within Brunswick-Wolfenbüttel. Ferdinand always appreciated it when those he supported attended his schools, but if they decided otherwise, he would still stand behind his students. This is what Gauss did in 1795. He packed up his bags and traveled 65 miles south to Göttingen to attend the university there. It had a solid reputation in the sciences and a good library. As with other institutions of higher learning at the time in Germany, the students were on their own. There were no mandatory classes or exams. The students were completely responsible for their education. Gauss took full advantage of this. He never did receive a Göttingen degree, but by the time that he left in 1798, he had laid the foundation for the mathematical research that would occupy much of his time over the next 25 years (Bühler 1981, 15, 17).

During his Göttingen years Gauss did not make many new friends. An exception was the Hungarian mathematician Farkas Bolyai, who he met in 1795. Bolyai was born on February 9, 1775 in the city of Bolya in Hungary. While he was a boy he attended the Lutheran and Calvinist College of Nagyenyed and showed a talent for mathematics. He was also skilled in music, drawing, and acting (Prékopa 2006, 11). While at the university, Gauss and Bolyai discovered that they shared an interest in the study of parallels. In June 1799, Bolyai left Göttingen to return to his home in Hungary, and for the next 54 years the two wrote frequently. In an example of their early correspondence from December 1799, Gauss discusses his attempts to prove the Parallel Postulate. He told Bolyai that he had tried to prove it by *reductio ad absurdum* arguments and had arrived at results that many would consider contradictory, but they were not. He wrote that because of this he had considered replacing the Parallel Postulate with another more intuitive one. He told Bolyai that "if it could be proved that a rectilinear triangle is possible with an area exceeding any given area," the Parallel Postulate would follow (Wolfe 1945, 128), but Gauss regarded such an assumption as no more likely to be true than the Postulate itself. As he had no experience with indefinitely producing two apparently parallel lines to see if they meet, Gauss had no experience with constructing arbitrarily large triangles. If the Parallel Postulate was to be replaced, any possible candidate must have at least some direct evidence in support of its truth (Bühler 1981, 16–17, 100–101; Bonola 1912, 65–66).

Gauss had wide and varying interests in addition to his mathematical studies. He was particularly fascinated with astronomy since his days at Caroline College. He enjoyed both the time at the telescope and the time crunching numbers, and he was good at both. He had the patience and attention to detail required of the discipline and the amazing ability for calculation that would bring him acclaim. The turn of the nineteenth century was an important time for astronomy. Uranus was discovered in 1781, and it would not be long until astronomers found Neptune in 1846. The instrumentation improved significantly, and with the aid that the newly discovered planets lent to orbital calculations, reliable sky maps were produced.

It was an event on January 1, 1801 that would set in motion a chain of events of which Gauss would take full advantage. The theory of the day stated that there should be a planet somewhere in the gap between Mars and Jupiter. On New Year's Day, Giuseppe Piazzi was observing the gap and thought that he had found the planet. He named it Ceres. We know it today as one of the larger minor planets in the asteroid belt. Piazzi successfully mapped approximately nine degrees of its orbit before it disappeared behind the "shadow of the sun." It was expected to reappear in late 1801 or early 1802, but since Piazzi had recorded only a little orbital data, where it would reappear was uncertain. Numerous astronomers made predications including Franz Xaver von Zach, one of Germany's top astronomers and the editor of the astronomical journal *Monatliche Correspondenz.* Gauss also made a prediction. When Ceres finally was sighted on December 7, 1801, it was Zach who found it. He published the results in the February issue of the *Monatliche Correspondenz*, proclaiming to the astronomical community that it was the mathematician Gauss whose prediction was closest. In 1809 Gauss published the full details of his technique in his famous *Theory of the Motion of the Heavenly Bodies Moving about the Sun in Conic Sections* (Pannekoek 1961, 352–353; Bühler 1981, 43–44, 46).

Gauss was well on his way to becoming the greatest mathematician of his day and possibly of all time. With the Ceres calculation he earned the distinction of being among the top astronomers. Such a reputation had its benefits. In 1802, he began discussions with the Brunswick government about building a new observatory. In that same year he received an invitation from the academy at St. Petersburg to become the director of their observatory. When the astronomer Wilhelm Obers, who had become a good friend of Gauss, heard this, he contacted the university at Göttingen in an attempt to convince them to offer Gauss the directorship of their newly planned observatory. He did not want Gauss to leave Germany. Although initial reaction was restrained, the administration did express interest, so negotiations began with Obers taking the lead. While all of this was happening, Gauss continued to pursue his scientific interests. Then in 1805, Obers finally finished the deal with Göttingen. The university offered to appoint Gauss the head of the observatory. If he accepted he would be very independent from the university, with little classroom time and nearly no administrative duties. The Brunswick observatory never materialized, and the offer was too good to refuse. So, in 1807, Gauss left Brunswick and returned to Göttingen (Bühler 1981, 45–46, 50–51).

Gauss began work again on the parallels problem in 1813. He began to realize that the Parallel Postulate could not be proven from the other axioms. He accepted what Saccheri could not: that there might be a geometry different from Euclid's. This realization must have made all of his strange discoveries make sense. His previous attempts were within a framework of looking for a contradiction. Now he understood that there was no contradiction. The results were strange only because they were viewed from a Euclidean point of view. They needed to be viewed as part of a completely different geometry. Gauss initially called this new system **anti-Euclidean geometry**, but finally settled on calling his system **non-Euclidean**

geometry, the term we use today for any geometry in which the Parallel Postulate does not hold (Bonola 1912, 66–67).

Gauss was very busy both as a mathematician and an astronomer. He had worked hard all of his life, and he valued his reputation. He would not risk it harm by publishing anything that might set him up for ridicule. For this reason he did not want his discoveries concerning the new geometry made public. He did not even trust the mathematical community to be ready to accept such results. In any age, new ideas that go against the mainstream must struggle for acceptance, and in the early nineteenth century Euclid was still king in mathematics and even philosophy. Not wanting to deal with such matters, Gauss only wrote about his research to a few select confidants. One of his few trusted friends was the mathematician and astronomer Friedrich Bessel, to whom in 1829 he wrote:

> It may take a very long time before I make public my investigations on the issue. In fact, it may not happen during my lifetime, since I fear the scream of the Boeotians were I to completely express my views.

The Boeotians were an ancient Greek tribe who were not known for their intelligence. Despite his concern, in 1831, Gauss began to compose his *Meditations*, in which he planned to summarize his discoveries concerning non-Euclidean geometry. He did not wish for his research on the theory of parallels to die with him (Burton 1985, 551; Bonola 1912, 67).

The Area of a Triangle

Although Gauss was involved with many different types of projects during the course of his career, he would occasionally return to the question of parallels. One such time was on March 6, 1832. Bolyai had again written on the question, and Gauss responded. In his letter he included among other things a proof that the defect of a triangle is proportional to its area (Wolfe 1945, 128–130). Gauss had previously written to Bolyai in 1799 about the fact that the Parallel Postulate follows if it could be shown that there is no greatest triangle with respect to area. However, Gauss could not disprove the existence of such a triangle, so instead he assumed that there was one to see what would happen. He realized that the maximum triangle would be the limit of a sequence of non-Euclidean triangles found by letting the triangles increase in area as one progresses through the sequence. As this happens, the sides of the triangle pinch in and the angles decrease in measure until the vertices become ideal points (Section 9.2) and the measures of the angles become zero (Figure 11.4). In these triangles with three ideal vertices, all sides are parallel to each other.

■ DEFINITION 11.3.1

A triangle in which at least one of its vertices is an ideal point is called an **omega triangle**. An **ordinary triangle** has no ideal vertices.

Now assume **HA** and let M represent the greatest possible area of a triangle. Take $\overline{AB}$ and two lines $\overline{CD}$ and $\overline{EF}$ which are both parallel to $\overline{AB}$ and meet at a point P as in Figure 11.2. (Be careful to note that this is now Saccheri's definition of parallel;

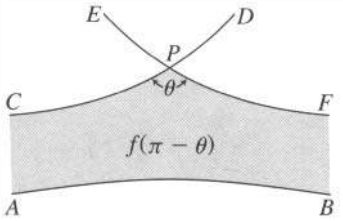

Figure 11.2 The area bounded by parallel lines.

see page 351.) Suppose that $m\sphericalangle CPF = \theta$. Define a function

$$f : [0, \pi] \to [0, M]$$

such that the area of the region bounded by these three lines equals $f(\pi - \theta)$. By the Saccheri-Legendre Theorem (11.2.7) we know that if $\theta = \pi$, the region can have no area. Therefore,

$$f(0) = 0.$$

If we take $\overline{CD}$ to be parallel to $\overline{EF}$ so that P is a point at infinity, then $\theta = 0$, and we have

$$f(\pi) = M.$$

Now imagine that the area transitions smoothly from 0 to M as θ ranges from π to 0. We see that it is not unreasonable to assume that f is not only continuous on $[0, \pi]$ but also differentiable. Furthermore, we infer from Figure 11.3 that

$$f(\pi - \theta) + f(\theta) = M$$

and

$$f(\theta) + f(\psi) + f(\pi - \theta - \psi) = M.$$

This last equation holds because

$$f(\pi - [\pi - \theta]) = f(\theta)$$

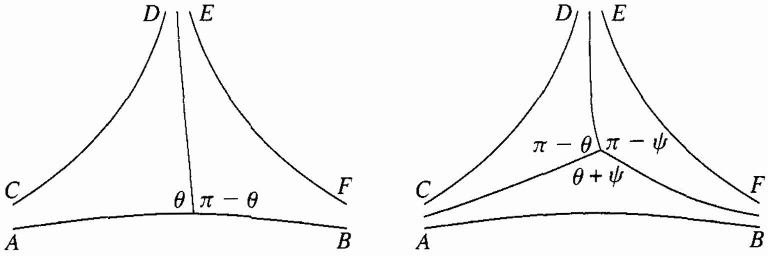

Figure 11.3 Omega triangles.

and

$$f(\pi - [\pi - \psi]) = f(\psi).$$

From this we conclude that

$$f(\psi) + f(\pi - \theta - \psi) = M - f(\theta) = f(\pi - \theta). \tag{11.2}$$

Next let $\gamma \geqslant 0$ be chosen such that $0 \leqslant \gamma \leqslant \pi$. Take $h \geqslant 0$, so that $\gamma + h \leqslant \pi$. Then there exists $\delta \geqslant 0$ such that $h = \pi - \delta - \gamma$. Notice that since $\delta = \pi - \gamma - h$, we have $0 \leqslant \delta \leqslant \pi$ and

$$\gamma + h = \gamma + \pi - \delta - \gamma = \pi - \delta. \tag{11.3}$$

From this we conclude that

$$f(\gamma + h) = f(\pi - \delta) = f(\gamma) + f(\pi - \delta - \gamma) = f(\gamma) + f(h),$$

where the first equation follows by Equation 11.3, the second by Equation 11.2, and the last by the definition of h. Hence for all α and β in the domain of f and $\alpha + h$, $\beta + h \leqslant \pi$,

$$\begin{aligned} f(\alpha + h) - f(\alpha) &= f(\alpha) + f(h) - f(\alpha) \\ &= f(\beta) + f(h) - f(\beta) = f(\beta + h) - f(\beta). \end{aligned}$$

This means that $f'(\alpha) = f'(\beta)$ for all α and β. It follows that there exists a constant $k > 0$ such that $f'(\theta) = k$, and since $f(0) = 0$ we see that for all θ, $f(\theta) = k\theta$. Because $f(\pi) = M$, we conclude that $M = k\pi$.

We are now ready to prove the result. Take a triangle with angles of measure α, β, and δ. Produce each of the sides as in Figure 11.4 and draw lines parallel to each of these extended sides producing a triangle with maximum area. Then

$$\text{area}(\triangle ABC) + f(\alpha) + f(\beta) + f(\delta) = M,$$

so

$$\text{area}(\triangle ABC) + k\alpha + k\beta + k\delta = k\pi.$$

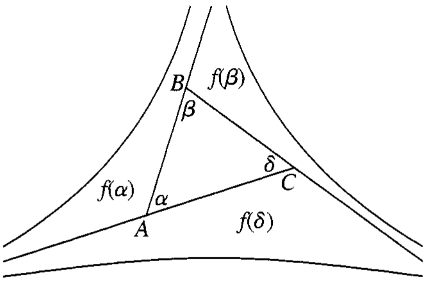

Figure 11.4 A triangle within a limiting maximum triangle.

From this we conclude that

$$\text{area}(\triangle ABC) = k(\pi - \alpha - \beta - \delta),$$

where $\pi - \alpha - \beta - \delta$ is the defect of the triangle. This shows that the area of a triangle is proportional to its defect assuming **HA**. This was a result also known to Lambert (Bonola 1912, 50).

Triangles with One Ideal Vertex

The omega triangle of Figure 11.4 has all of its vertices as ideal points. The triangles that we examine in this section will have only one ideal point as a vertex (see the figure for Theorem 11.3.4). These triangles share some of the same properties as regular triangles under **HA** (Wolfe 1945, 71–75).

Our first two results rely on an assumption that we have used before but now state explicitly. The postulate is named for Moritz Pasch, who in the late nineteenth century made significant contributions to the understanding of the logic behind geometry (Kline 1972, 1008). For these results, we say that a line **enters** a triangle if it contains a point on the interior of the triangle and either intersects a side or contains a vertex.

■ POSTULATE 11.3.2 [Pasch]

If a line enters an ordinary triangle through a side and does not contain one of its vertices, the line intersects exactly one of the other sides of the triangle.

The proof of the corollary is left for Exercise 2.

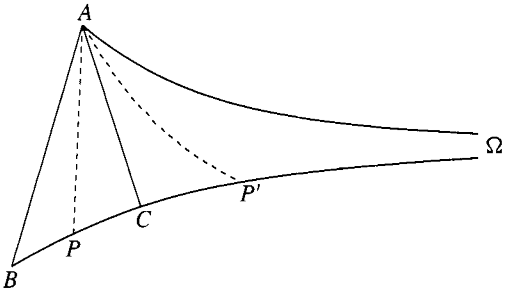
■ COROLLARY 11.3.3 [Pasch]

If a line enters an ordinary triangle through a given vertex, the line intersects the side of the triangle that is opposite the given vertex.

The next two theorems generalize these two propositions to omega triangles. We prove the first one here, but leave the second to Exercise 3.

■ THEOREM 11.3.4

[HA] If a line enters an omega triangle through a given vertex, the line will intersect the side opposite the given vertex.



PROOF

Let $\overline{A\Omega}$ be parallel to $\overline{B\Omega}$. Find C on $\overline{B\Omega}$ such that $\overline{AC}$ is perpendicular to $\overline{B\Omega}$. If a line enters $\triangle AB\Omega$ through A, there are three options. The line could be on $\overline{AC}$. In this case it intersects $\overline{B\Omega}$ at C. It could lie on a line on the interior of $\measuredangle BAC$, but by Corollary 11.3.3 this line must intersect $\overline{BC}$ at some point P. Finally, if the line is on the interior of $\measuredangle CA\Omega$, it is below the parallel $\overline{A\Omega}$. Hence, it must intersect $\overline{C\Omega}$ at some P' by the definition of parallel line (Theorem 10.5.2 and page 351). ■

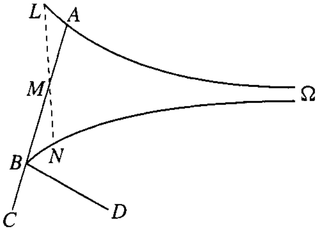
■ THEOREM 11.3.5

[HA] If a line enters an ideal triangle through a side and does not contain one of its vertices, the line intersects exactly one of the other sides of the triangle.

An important theorem regarding ordinary triangles states that an exterior angle is greater than either of its opposite interior angles (Theorem 5.3.9). The next theorem states that this also holds for triangles with an ideal vertex.

■ THEOREM 11.3.6

[HA] The exterior angles of $\triangle AB\Omega$ at A and B are greater than their respective opposite interior angles.



PROOF

In $\triangle AB\Omega$ produce $\overline{AB}$ to C. We will prove $m\measuredangle CB\Omega > m\measuredangle BA\Omega$. Copy $\measuredangle BA\Omega$ at B, producing $\measuredangle CBD$. First notice that $\overline{BD}$ will not intersect $\overline{A\Omega}$, else we would have a triangle in which one of its external angles is congruent to one of the opposite internal angles, and this would contradict Theorem 5.3.9. Therefore, $\overline{BD}$ is on the interior of $\measuredangle CB\Omega$ or D is on $\overline{B\Omega}$. Suppose the latter. This means that $\measuredangle CBD$ and $\measuredangle CB\Omega$ are the same angle. Let M be the midpoint of $\overline{AB}$ and find N on $\overline{B\Omega}$ such that $\overline{MN}$ is perpendicular to $\overline{B\Omega}$. Produce $\overline{A\Omega}$ to a point L through A such that $\overline{LA} \cong \overline{BN}$. Since our assumption on D implies that $\measuredangle CB\Omega \cong \measuredangle BA\Omega$, we have $\measuredangle LAM \cong \measuredangle NBM$. Thus, $\triangle MAL \cong \triangle MBN$ by SAS, and we may conclude that L, M, and N are collinear because $\measuredangle LMA \cong \measuredangle BMN$ (Theorem 5.3.8). From this we conclude that $\overline{LN}$ is perpendicular to both $\overline{A\Omega}$ and $\overline{B\Omega}$, but these two lines are parallel. This is a contradiction of **HA** (specifically, Theorem 10.5.2). Therefore, $\overline{BD}$ must lie on the interior of $\measuredangle CB\Omega$, which means that $m\measuredangle CB\Omega$ is greater than $m\measuredangle BA\Omega$. ■

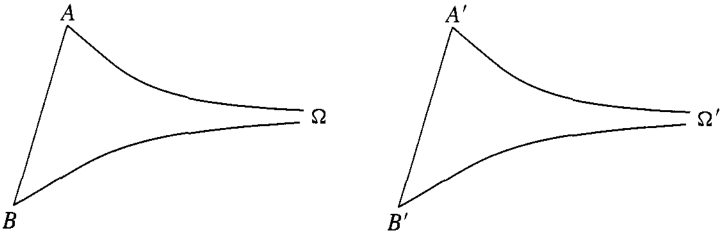


Figure 11.5 $\triangle AB\Omega \cong \triangle A'B'\Omega'$.

We finish the section by looking at what it means for two omega triangles with exactly one ideal vertex each to be congruent. Since any segment that has an ideal point as an endpoint is considered to be infinite in length, and since any angle that has an ideal point as a vertex is considered to have zero measure, we need to check only three conditions to show that these types of triangles are congruent (Figure 11.5).

■ DEFINITION 11.3.7

We say that $\triangle AB\Omega$ is **congruent** to $\triangle A'B'\Omega'$ if

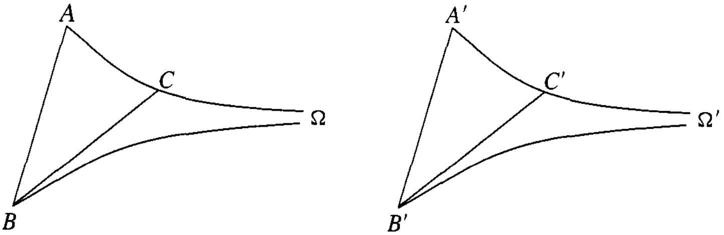
- $\overline{AB} \cong \overline{A'B'}$
- $\sphericalangle AB\Omega \cong \sphericalangle A'B'\Omega'$.
- $\sphericalangle BA\Omega \cong \sphericalangle B'A'\Omega'$.

In this case we write $\triangle AB\Omega \cong \triangle A'B'\Omega'$.

We need to confirm only two of the three conditions to guarantee that a pair of such omega triangles are congruent.

■ THEOREM 11.3.8 [SA]

[HA] If $\overline{AB} \cong \overline{A'B'}$ and $\sphericalangle BA\Omega \cong \sphericalangle B'A'\Omega'$, then $\triangle AB\Omega \cong \triangle A'B'\Omega'$.



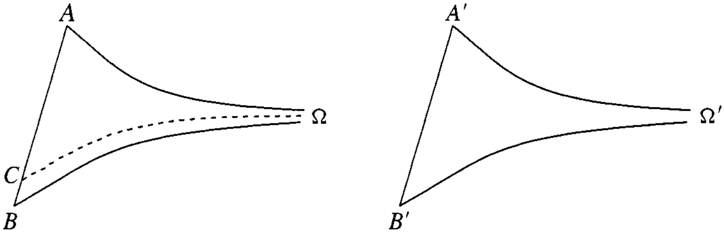
PROOF

Let $\overline{AB} \cong \overline{A'B'}$ and $\sphericalangle BA\Omega \cong \sphericalangle B'A'\Omega'$. We need to show that $\sphericalangle AB\Omega$ is congruent to $\sphericalangle A'B'\Omega'$. Suppose instead that $m\sphericalangle AB\Omega > m\sphericalangle A'B'\Omega'$. This means that there is a line on the interior of $\sphericalangle AB\Omega$ that forms an angle congruent to $\sphericalangle A'B'\Omega'$. This line must intersect $\overline{A\Omega}$ at some point C (Theorem 11.3.4). We may now write $\sphericalangle ABC \cong \sphericalangle A'B'\Omega'$. Next find C' on $\overline{A'\Omega'}$ such that $\overline{AC} \cong \overline{A'C'}$. We conclude that $\triangle BAC \cong \triangle B'A'C'$ by SAS. Therefore, $\sphericalangle ABC \cong \sphericalangle A'B'C'$. This is a contradiction because $\sphericalangle A'B'C' \cong \sphericalangle A'B'\Omega'$ by transitivity, but $\overline{B'C'}$ is on the interior of $\sphericalangle A'B'\Omega'$. The case when $m\sphericalangle AB\Omega$ is less than $m\sphericalangle A'B'\Omega'$ leads to a similar contradiction. ■

Our last theorem has a familiar name but an unfamiliar result. Compare this with Theorem 11.2.15.

■ THEOREM 11.3.9 [AA]

[HA] If $\sphericalangle BA\Omega \cong \sphericalangle B'A'\Omega'$ and $\sphericalangle AB\Omega \cong \sphericalangle A'B'\Omega$, then $\triangle AB\Omega$ is congruent to $\triangle A'B'\Omega'$.



PROOF

Suppose that $\sphericalangle AB\Omega \cong \sphericalangle A'B'\Omega'$ and $\sphericalangle BA\Omega \cong \sphericalangle B'A'\Omega'$ in $\triangle AB\Omega$ and $\triangle A'B'\Omega'$, but $\overline{AB}$ is not congruent to $\overline{A'B'}$. This means either $AB > A'B'$ or $AB < A'B'$. It is enough to show that the first inequality leads to a contradiction, so suppose that we can find C on $\overline{AB}$ such that $\overline{AC} \cong \overline{A'B'}$. Thus, by SA, $\triangle AC\Omega \cong \triangle A'B'\Omega'$, which gives $\sphericalangle AC\Omega \cong \sphericalangle A'B'\Omega'$. Therefore, $\sphericalangle AC\Omega \cong \sphericalangle AB\Omega$ by transitivity. However, we know by Theorem 11.3.6 that $m\sphericalangle AC\Omega > m\sphericalangle AB\Omega$ because $\sphericalangle AC\Omega$ is exterior to $\triangle CB\Omega$. Therefore, $\overline{AB} \cong \overline{A'B'}$ and we conclude that $\triangle AB\Omega \cong \triangle A'B'\Omega'$. ■

Exercises

All problems except the first assume the Hypothesis of the Acute Angle.

1. Explain why Pasch's Postulate (11.3.2) is implied by the following statement: *If a line enters an ordinary triangle through a side and does not contain one of its vertices, the line intersects one of the other sides of the triangle.*

2. Prove Corollary 11.3.3.

3. Prove Theorem 11.3.5.

4. Let l intersect side $\overline{AB}$ of convex quadrilateral $ABCD$ and contain a point in the interior of $ABCD$. Prove that exactly one of the following holds: C is on l, D is on l, l intersects $\overline{BC}$, l intersects $\overline{CD}$, or l intersects $\overline{AD}$.

5. What proposition must be true in order for the area of a quadrilateral to be proportional to its defect? Assuming this proposition to be true, prove that the area of a quadrilateral is proportional to its defect.

6. Show that in $\triangle AB\Omega$ the sum of $m\sphericalangle AB\Omega$ and $m\sphericalangle BA\Omega$ is less than two right angles.

7. Let $\triangle AB\Omega$ be an omega triangle such that $\sphericalangle AB\Omega \cong \sphericalangle BA\Omega$. Let M be the midpoint of $\overline{AB}$ and let $\overline{M\Omega}$ be the line through M that is parallel to both $\overline{A\Omega}$ and $\overline{B\Omega}$. Prove that $\overline{M\Omega}$ is perpendicular to $\overline{AB}$.

8. Let A, B, and C be collinear with B between A and C. Let $\overline{AC}$ be perpendicular to $\overline{C\Omega}$. Demonstrate that $m\sphericalangle CA\Omega < m\sphericalangle CB\Omega$.

9. Show that the A in SA cannot be dropped by drawing two noncongruent omega triangles that have congruent corresponding sides.

10. Show that one of the A's in AA cannot be dropped by drawing two noncongruent omega triangles that have one pair of congruent corresponding angles

11. Let B be on $\overline{A\Omega}$ and C on $\overline{A\Omega'}$. Assume that $\overline{A\Omega}$ is perpendicular to $\overline{A\Omega'}$. Prove:
   (a) $\overline{B\Omega'}$ intersects $\overline{C\Omega}$ in a point D.
   (b) If $\overline{AB} \cong \overline{AC}$, then $\triangle BD\Omega \cong \triangle CD\Omega'$.

12. Let Ω and Ω' be on opposite sides of $\overline{AB}$. Suppose that $\overline{A\Omega}$ and $\overline{B\Omega'}$ are perpendicular to $\overline{AB}$. Prove that $\sphericalangle AB\Omega \cong \sphericalangle BA\Omega'$.

13. Does the Pythagorean Theorem hold when **HA** is assumed? Explain.

14. In $\triangle AB\Omega$ and $\triangle A'B'\Omega'$ we have $\sphericalangle AB\Omega \cong \sphericalangle A'B'\Omega'$ and $AB > A'B'$. Show that $m\sphericalangle BA\Omega < m\sphericalangle B'A'\Omega'$.

11.4 PURE REASON

Immanuel Kant was born in Königsberg on April 22, 1724 to Johann Georg and Ann Regina Kant. Immanuel was born the fourth child, but only an older sister was still alive at the time of his birth. Immanuel's father was a master harness maker and his mother was the daughter of a harness maker. Due to his father's expertise in his trade, the family lived well but not extravagantly and was very dependent on the local economy. As trade decreased in Königsberg, so did the family's fortunes, but they never reached a level that we would consider poor. Those early years with his family taught Kant the virtues of hard work, self-reliance, and honesty. Like his father before him, Kant determined that he would be a self-made man (Kuehn 2001, 26–31).

Kant's parents were very religious and greatly influenced by the Pietist movement within the Lutheran church. Pietism appeared in the late seventeenth century and was prominent in the first half of the eighteenth century. As a reaction to a church whose members appeared simply to be going through the motions, the Pietists attempted to bring back a living Christianity. Kant's parents wanted their son to receive a sound eduction, so they sent him to the Pietist *Collegium Fridericianum*. Little is known about the details of Kant's religious beliefs, but it is known that Kant hated the school. Even though it provided Kant with a good education and a chance for social advancement, he despised the school's attempts to convert him and the suffocating moralism of the faculty (Kuehn 2001, 34–35, 39–40, 45, 51–52, 54).

Not only did the Pietists run the *Collegium Fridericianum*, but they grew in influence at the University of Königsberg, where Kant began to study in 1740, when he was 17. The city of Königsberg was an important but remote city in northeastern Prussia near the Russian border. This remoteness had its disadvantages. It was difficult to recruit faculty, and the 44 full professors who were on staff earned low salaries. The remaining faculty were not paid by the university but instead were ***privatdozents***, faculty who were allowed to charge their students directly for attending their lectures. Kant would have attended both the free lectures given by those on the university's payroll and the paid ones. From these courses he learned subjects which included general philosophy, metaphysics, logic, ethics, natural law, physics, systematic theology, rhetoric, history, poetry, psychology, and mathematics. While at the *Collegium Fridericianum*, Kant became particularly interested in the classics, and he continued those studies at the university (Kuehn 2001, 45, 56, 63, 73, 75, 76).

A turning point came in 1744. Under the influence of faculty from both philosophy and physics, Kant turned to philosophy and began work on his first major philosophical piece. It was titled *Thoughts on the True Estimation of the Living Forces*. The work is a critique of both Newton and Leibnitz. Some also surmise that it contains a veiled attack on some of the Königsberg faculty. Eventually, this made Kant's life at Königsberg uncomfortable. 1744 also saw tragedy in the Kant family. Kant had lost his mother seven years earlier, and this year his father suffered a stroke that would lead to his death in 1746. This, combined with the turmoil at school and the fact that he had finished his formal studies, led to Kant's decision to leave Königsberg in 1748 and move to the surrounding countryside (Kuehn 2001, 80, 81, 86, 89–95).

There Kant became a private tutor. The position did not hold a high social status. It was something akin to a servant, and many who did not succeed at the university found themselves teaching the children of those wealthy enough to afford it. From the time he left his home to 1754, Kant worked for various families in Judtschea, Arnsdorf, and Rautenburg. He never did consider himself very good at teaching children, but his students and their parents thought otherwise and kept in contact with him long after his work was done (Kuehn 2001, 95–97).

It was apparently Kant's goal not to stay away from Königsberg forever. While working as a tutor he continued his research. In 1749 he published his *True Estimation of Living Forces*, and in 1754 he returned to Königsberg. On April 7 of the following year he turned in his dissertation. It was titled "Succinct Meditations on Fire," and in

June he made a public defense, the final step to his doctorate. At this point, however, Kant did not have the right to teach at the university. To earn this he would have to present another dissertation, called a ***Habilitationsschrift***, and then give a public lecture, the ***Habilitationsvortrag***. This occurred in September 1755 when he gave a talk entitled "A New Exposition of the First Principles of Metaphysics." For the next 15 years Kant taught students, conducted research, sought to be appointed to the position of full professor, and wrote. Some of his titles include *General History and Theory of the Heavens* (1755), *The Only Possible Argument in Support of a Demonstration of the Existence of God* (1763), *Observations on the Feeling of the Beautiful and Sublime* (1764), and his "prize essay" for the Prussian Academy of Sciences in Berlin entitled *Inquiry Concerning the Distinctness of the Principles of Natural Theology and Morality* (1764) (Kuehn 2001, xv–xvii, 98, 100).

Then in 1765, Kant received a letter that would begin a correspondence that would last for 12 years. It was from Lambert, who had read Kant's *The Only Possible Argument in Support of a Demonstration of the Existence of God* and found thoughts very similar to his own. Lambert was confident that if Kant would read his *Neues Organon* and *Anlage zur Architectonik*, Kant would share in this opinion. In writing, Lambert sought to exchange letters on subjects ranging from mathematics to metaphysics, with his main interest being Kant's views regarding space and time. Lambert wanted to prove that Euclidean geometry was true but had been unsuccessful. This caused him to recognize the logical possibility of an alternative geometry. Although Kant would reject Lambert's view of space, their letters greatly aided Kant's research and helped direct Kant's writing of his *Critique of Pure Reason* (Kant 1999, 77–79, 81–82; Kuehn 2001, xvii, 181, 196, 231).

The creation of the *Critique* began when the University of Königsberg appointed Kant to be professor of logic and metaphysics in 1770. Again a paper and a talk were required. Kant defended this inaugural dissertation on August 21. He sent a copy to Lambert a month later and wrote to him that he expected to quickly produce a major work from it by making only minor modifications. Kant later claimed that it took him four to five months of work to finish the *Critique*, but it was the result of 11 years of contemplation. In May 1781 the *Critique* was published, followed by a second edition in 1787. The fundamental question that Kant sought to answer was: "What can I know?" He concluded that traditional philosophy erred when it taught that one can discover truths about the world independent of experience. Instead, all of our knowledge of the world is obtained through the senses, but the structure that we put on those perceptions exists in our minds independent of any sensory input. The structure that we put onto space, for example, is described by Euclid's geometry. Metaphysics then becomes the study of the presuppositions of experience. We can only know the world as it appears to us, never as it actually is. Kant called his position **transcendental idealism** (Kuehn 2001, 231, 240–243, 246).

Kant intended to dedicate the *Critique of Pure Reason* to his good colleague Johann Lambert, but Lambert died on September 27, 1777 shortly before its publication. Lambert never saw the *Critique* in its final form, nor did he see the publication of his own work on geometry, entitled *Theory of Parallel Lines*. It was published in 1786 by Johann Bernoulli along with much of Lambert's correspondence, including his letters to Kant (Kuehn 2001, 231, 254; Kant 1999, 185–187; Boyer and Merzbach 1991, 462).

Describing Knowledge

Saccheri believed that the Parallel Postulate was true, so he went looking for a proof. He found one that he trusted, so he believed that the Postulate held. However, we know that his proof was not valid. We conclude that regardless of the truth of the Parallel Postulate, Saccheri did not know its truth value. This is because his reason for his belief was not sound. We base this conclusion on the definition of what it means to know that a statement is true.

■ **DEFINITION 11.4.1**

For a person to have **knowledge** that a proposition is true, three conditions must be satisfied:

- The person believes that the proposition is true.
- The statement is in fact true.
- The person has good reason to believe that the proposition is true.

The definition of knowledge and the discussion of this section is adapted from Halverson (1981, 25–63).

To clarify what it means to know that a proposition is true, let us examine a sentence that is simpler than the Parallel Postulate. Let p represent the claim that

there exist unicorns on Mars.

What would it mean for us to know p? With respect to the three conditions, it means:

- To know proposition p, we must first affirm it to be true. This is the bare minimum. If we believe that there are no unicorns on Mars, then whether there are unicorns or not, how could it be said that we know that they exist?
- Of course, simply believing p does not make it so. For us to know p, it must also be the case that p is true. If we believe that there are unicorns on Mars and there are none, we do not know that there are unicorns on Mars. Instead we believe a proposition that is false.
- Suppose that it is indeed the case that unicorns live on the red planet and we believe it. This is still not enough for us to be able to claim knowledge of this state of affairs. We must add to this a good reason to give credence to our belief. If we do not, we have no reason to have any confidence that our belief is accurate even though in reality it might be.

To have knowledge that p is true, we need the three listed conditions to hold, and it is crucial that we do not overlook the need for an adequate justification of our beliefs.

So what would be adequate justification for believing the Parallel Postulate? It depends on the type of proposition it is. Let us first compare it to p. Any justification of p requires information about the unicorns that is not included in the sentence. We need a photograph, a reliable eye witness, or some other kind of evidence that the words of the sentence do not provide. Nothing from the definition of a unicorn suggests that they live on Mars. Hence, the sentence p claims to give new information about its subject. Does the Parallel Postulate also claim to give new information about lines? The Postulate states that

> *if a straight line falling on two straight lines make the interior angles on the same side less than two right angles, the two straight lines, if produced indefinitely, meet on that side on which the angles are less than the two right angles.*

If there is something that the Parallel Postulate tells us about lines that is not included in the meaning of the word *line*, it is a sentence like p and requires evidence to determine its truth.

However, consider the assertion that

all bachelors are unmarried men.

For this statement no additional information is required to determine its truth. The definition of *bachelor* gives it to us. A bachelor is an unmarried man, and this is what the sentence states. It tells us nothing new about its subject. If the Parallel Postulate more closely resembles this type of assertion, observation is not needed to determine its truth. We need only to analyze the meanings of the words and possibly apply some logic. This and the previous case exhaust the possibilities, so we can make the following definitions.

■ **DEFINITION 11.4.2**

A **synthetic** proposition is one that gives new information about its subject.

■ **DEFINITION 11.4.3**

An **analytic** proposition is one that is not synthetic. It does not give new information about its subject.

The sentence *there exists unicorns on Mars* is synthetic. Either direct or indirect experience of the unicorns is required to prove it. If such evidence is found, we believe it, and if the sentence turns out to be true, we have gained knowledge of a particular type.

■ **DEFINITION 11.4.4**

Knowledge that is based on experience is called ***a posteriori***.

The term *a posteriori* refers to the knowledge coming *after* having experienced the state of affairs described by the sentence. If knowledge comes *before* experience,

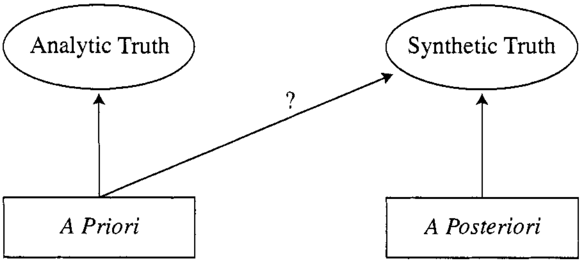


Figure 11.6 *A priori* and *a posteriori* knowledge.

such as that gained from the sentence *a bachelor is an unmarried man*, then it is not *a posteriori*. We do not need to meet a bachelor or have any other type of experience involving bachelors to know that the sentence is true. This represents the second type of knowledge.

■ **DEFINITION 11.4.5**

Knowledge that is not based on experience is called ***a priori***.

Based on our examples we may summarize by stating that we have *a posteriori* knowledge of some synthetic truths and we have *a priori* knowledge of some analytic truths. Can we push this further? Certainly all analytic propositions are known *a priori*, and all *a posteriori* knowledge is synthetic (Figure 11.6). However, is it possible to know a synthetic proposition *a priori*? Our answer to this question will put us into one of two mutually exclusive camps.

■ **DEFINITION 11.4.6**

A **rationalist** believes that there exists a true proposition about the world that can be known without either direct or indirect experience of it.

A rationalist does not deny that many propositions that describe the world accurately are known by observation. The claim is that there is at least one proposition that says something true about the world, yet we determine its truth simply by analyzing the terms of the sentence.

■ **DEFINITION 11.4.7**

An **empiricist** believes that the only way to know a true proposition about the world is by either direct or indirect experience of it.

The empiricist believes that there is no sentence that gives us new information about the world, yet we know it *a priori*. Only experiment or some other type of observation can lead to knowledge of the universe.

It is not uncommon for a scientist to speak as if the only way to learn about the universe is through the scientific method. All other modes of discovery are either analytic or superstition. It appears that scientists are empiricists. The rationalist will counter that this is a hasty generalization. There are synthetic *a priori* truths, and examples can be found in mathematics. This is what Kant believed.

Intuition

Mathematics served as Kant's main example of knowledge that is both *a priori* and synthetic. For example, consider Euclid's theorem regarding the sum of the interior angles of a triangle being equal to two right angles. Kant believed that this proposition is synthetic. Simply analyzing the meanings of the terms of the sentence will not yield whether the statement is true or not. We understand what *interior*, *angle*, and *triangle* mean, but none of their meanings involve *sum*, *two*, or *right*. We must arrive at the conclusion by some other way (Shabel 2006, 98).

The way to arrive at this conclusion is a method that Kant believed is unique to mathematics. Consider first this nonmathematical example. When we look at a tree, the light rays reflect off its surface and hit our eyes, which send signals along our optic nerves to our brains. We then carry the resulting image of the tree with us mentally. Kant had a name for this.

■ **DEFINITION 11.4.8**

An **intuition** is the immediate representation of an object in one's mind. An intuition that is caused by an object acting upon us in some way is called an **empirical intuition**, and one that is independent of any sensation is called a **pure intuition**.

The mental picture of the tree is an example of an empirical intuition. If we read the definition of a triangle, we see in our mind what it looks like based on the definition without needing a picture of the triangle. This is a pure intuition. From these intuitions we derive concepts.

■ **DEFINITION 11.4.9**

A **concept** is an abstract generalization of an intuition without the influence of the associated object.

We take our mental picture of the tree or the triangle and from that picture alone we create categories into which we place our intuitions. When we see other trees, new intuitions form in our minds, and the concepts that we have generalized from other intuitions allow us to group like intuitions under the same categories (Kant 1998, A19/B33, 155; cf. 36). This is illustrated in Figures 11.7 and 11.8.

Kant pulls this together to describe the very unique job of mathematicians. They arrive at truth by way of construction. According to Kant (1998, A713/B741, 630), "to **construct** a concept means to exhibit *a priori* the intuition corresponding to it." This means that if we take a mathematical concept, that of a triangle for instance, that

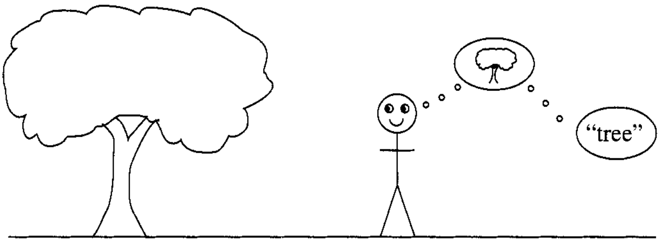

Figure 11.7 An empirical intuition leads to a concept.

is represented in our minds as an intuition, to construct that concept we must explain, illustrate, or describe the intuition in some way. The result is called a **construction**. Think of it as a picture that represents the concept. It can either be in one's mind or on a piece of paper. Either way, a construction is a generalization derived from the concept. For example, the construction of a triangle on paper is drawn in such a way that the lengths of its sides and the measures of its angles are irrelevant. What is important in the picture are the general properties of the triangle (Kant 1998, A 713–A 714/B 741–B 742, 630).

It is such constructions that make mathematical propositions synthetic. We see this in Kant's comparison between the philosopher and the mathematician. Consider the geometric proposition which states that the angle sum of a triangle equals two right angles. Philosophers will proceed by analysis. They will examine the meanings of *angle* and *side* and *vertex* and attempt to find within these terms a nugget of truth that will enable them to conclude the result about the angle sum. They will not find it. The mathematicians will find it because they will look beyond the definition. Their mental picture tells them that if through a vertex they draw a line parallel to the opposite side, they will see the angles of the triangle lying along the parallel at the chosen vertex. The truth about the angle sum is a synthetic one. The sentence gives us information about the triangle that goes beyond its definition, and it is the construction that shows this. Kant argued that this not only works for geometry but also for arithmetic. For example, the sentence *one plus one equals two* is synthetic because it tells us information about *one*, *two*, *plus*, and *equals* that go beyond their

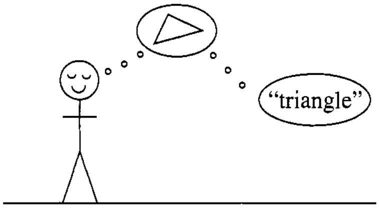

Figure 11.8 Pure intuition leads to a concept.

meanings. We then generalize to basic rules based on our intuition of numbers and addition. Because all of mathematics is either the study of the continuous (geometry) or the discrete (arithmetic), all mathematical propositions are synthetic (Shabel 2006, 101, 106–107; cf. Kant 1998, A 716/B 744, 631–632).

Now Kant asserts that mathematical knowledge is *a priori*. The example will again be the angle sum theorem for triangles. He claims that the proposition has two properties that make it clear that it entails *a priori* knowledge. They are the statement's necessity and universality. Kant claims that the angle sum result must be true because of its proof. The geometric demonstration does not depend on conclusions that are based on experimental evidence that later could be proven wrong. Instead, the proof transcends time and gives the geometer complete certainty of the proposition's truth. Necessity is not a quality that is determined *a posteriori*. We cannot determine whether a statement must be true by experiment alone. As for the fact that the sentence holds for all triangles at all times follows from the very act of construction. Indeed, the triangle constructed is a particular instance of the term, so the construction is particular, not universal. The algorithm that leads to the construction flows from the concept of triangle, and it is the same each time an arbitrary triangle is needed. This universality is also something that our senses cannot give us. When we try to generalize based on multiple observations, there is always at least some doubt that the next observation will not uphold our conclusion. Both necessity and universality are characteristics of *a priori* knowledge and not *a posteriori*. Because arithmetic propositions also have these two characteristics, Kant concluded that all of the true propositions of mathematics are instances of synthetic *a priori* knowledge (Shabel 2006, 107–109).

We may now define a **mathematical concept** as a synthetic definition that gives us the rule for describing the associated intuition. The definition of a triangle is an example. It tells us that to construct a triangle we need three noncollinear line segments joined at their endpoints. We now know how to construct it. This is an example of a specific type of mathematical concept called a **geometric concept**. Kant taught that geometric concepts give us a pattern for constructing space (Shabel 2006, 99). This means that since geometry is *a priori* and necessary, the same can be said about space. It is a pure intuition. It is not something that exists outside ourselves but originates in our minds as a fundamental framework to put meaning onto the input from our senses. Kant held this position against two prevailing views in which space exists in an objective sense either as the final container of objects or as an abstraction from the relations among the objects. He regarded the first view as untenable because it would make space into some kind of substance that was infinite in extent, and only God can be said to have such a quality. Moreover, Kant viewed God as existing outside space and time, and this appears to be impossible if the universe is infinite in size. Kant rejected the second view because it was not consistent with geometry being both necessarily true and an accurate description of the world. If space is abstracted from what we see, the structure of space is discovered by empirical means. This would mean that geometry is not *a priori* as Kant claimed.

To support his view, Kant notes that for us space is assumed by our minds when we use our senses. The standard example is that of a pair of hands. When we examine them, they are from our point of view essentially identical. To our eyes they look the same. If we measure the lengths of the fingers, the distance around the wrists, and so on, we find that they have the same dimensions. How, then, do we tell the left hand from the right? We are able to do this, according to Kant, because our spatial intuition comes preloaded with such concepts as up, down, in front, behind, and to the side. These *a priori* properties of space enable us to make the distinction. That this ability is universal in humans is further support for Kant's view. Since space is neither an object that exists independent of ourselves nor an abstraction based on observation, there are no competing realities when it comes to space. Everyone has the same intuition about its nature, and that intuition is described by Euclid's geometry. The mathematics that describe the universe is common to all people because everyone has the same intuition about space (Hatfield 2006, 73–78).

CHAPTER 12

NICOLAI LOBACHEVSKI AND JÁNOS BOLYAI

After he left Göttingen in 1799, Farkas Bolyai moved to the Hungarian city of Kolozsvár, where he began work as a tutor. He met Zsuzsanna Árkosi Benkő, and they soon were wed. The couple moved to Domáld but returned to Kolozsvár in the fall of 1802 expecting their first child. The baby was a boy, and they named him János (Prékopa 2006, 11).

János was a child prodigy. When he was 6, he taught himself to read. When he was 7 he learned German and how to play the violin. His father began to teach him mathematics when he was 9. He began formal schooling when he was 12, skipping the first three grades. János could easily solve calculus problems by the time he was 14. Passing his final exam in 1817 when he was 15 years old, he was ready to attend a university. The problem was that there were none in the local vicinity, and the closest ones, the University of Pest and the University of Vienna, did not have the caliber of mathematics faculty necessary to further János' education. The obvious solution was to send him to Gauss at Göttingen, so Farkas wrote his friend. At such a young age János would need proper supervision, so he inquired of Gauss whether his son might stay with him during his time at the university. Unfortunately, the letter could have been more tactfully written, for Farkas wanted to confirm that the Gauss household provided the proper environment for his son. It must be that Gauss was

Revolutions of Geometry. By Michael O'Leary

not "grumbling," his wife "exceptional," and his daughter not "dangerous." It is not surprising that Gauss did not answer the letter. It is a testament, however, to their friendship that this incident did not prevent future amicable correspondence (Prékopa 2006, 14–15).

So instead János attended the Vienna Academy of Military Engineers. Due to some financial problems, he enrolled a year later, in 1818. He excelled in his studies, and János was ranked first in his class by his professors. There was also a ranking based on student input in which he ranked second in his class. János did not enjoy drawing and his performance reflected this. This was evidently enough to keep him from first place. However, what he did enjoy was mathematics. Like his father he excelled at it, and like his father he was drawn to the study of parallel lines. Beginning in 1820 János researched the field thoroughly. His goal was to prove the Parallel Postulate once and for all. Learning of his son's intentions, Farkas wrote to him in a letter dated April 4, 1820 (Prékopa 2006, 15–16):

> You must not attempt this approach to parallels: I know this way to its very end. I have traversed this bottomless night, which extinguished all light and joy of my life. For God's sake! I entreat you leave parallels alone, abhor them like indecent talk, they may deprive you [just like me] from your time, health, tranquility and the happiness of your life. That bottomless darkness may devour a thousand tall towers of Newton and it will never bright up in the earth. ... I thought I would sacrifice myself for the sake of the truth. I was ready to become a martyr who would remove the flaw from geometry and return it purified to mankind. I accomplished monstrous, enormous labors; my creations are far better than those of others and yet I have not achieved complete satisfaction. ... I turned back when I saw that no man can reach the bottom of this night. I turned back unconsoled, pitying myself and all mankind. ... I have traveled past all reefs of this infernal Dead Sea and have always come back with broken mast and torn sail. The ruin of my disposition and my fall date back to this time. I thoughtlessly risked my life and happiness — *aut Caesar aut nihil.*

Evidently, Farkas's letter inspired János. If the Parallel Postulate could not be proven, then what? It should be replaced by something else, not with a statement that is equivalent to it because that would simply lead to all of the same problems that his father had encountered. Instead, the Parallel Postulate should be replaced by an assumption that would imply the Postulate's negation. He would continue his research. In 1822 János finished his studies at the Academy, but because he was one of their top two students, the school allowed him to stay an extra year. When he left Vienna after his extension, János was advanced to the position of sub-lieutenant and was assigned the position of Directorate of Fortification of Temesvár. It was there where things fell together. On November 3, 1823 he wrote to his father:

> I am resolved to publish a work on parallels as soon as I can complete and arrange the material, and the opportunity arises. At the moment I still do not clearly see my way through, but the path which I have followed is almost certain to lead me to my goal, provided it is at all possible. I have not quite reached it, but I have discovered things so wonderful that I was astounded and it would be an everlasting pity if these things were lost. When you, my dear father, see them, you will understand. All I can say at present is that out of nothing I have created a strange new world. All that I have sent you previously is like a house of cards in comparison with a tower. (Burton 1985, 554)

Possibly reflecting on the discovery of analytic geometry by Descartes and Fermat and that of the calculus by Newton and Leibnitz, Farkas wrote to János:

> It seems to me advisable, if you have actually succeeded in obtaining a solution of the problem, that, for a two-fold reason its publication be hastened: first, because ideas easily pass from one to another who, in that case, can publish them; secondly, because it seems to be true that many things have, as it were, an epoch in which they are discovered in several places simultaneously, just as the violets appear on all sides in the springtime. (Burton 1985, 554)

In 1825 János sent an abstract to his father, and then finally in 1829 he sent a copy of the work. Farkas was pleased but concerned about one point. An indeterminant constant appeared in his formula, and he did not understand why his son could not eliminate it. Nonetheless, the two came to agreement, and János's work would be appended to Farkas's *Essay on the Elements of Mathematics for Studious Youths*. The full title of János's text in Latin is *Appendix scientiam spatii absolute veram exhibens: a veritate aut falsitate Axiomatis XI. Euclidei, a priori haud unquam decidenda, independentem: adjecta ad casum falsitatis quadratura circuli geometrica*. This is shortened in English to *The Science of Absolute Space*, and it is often referenced simply as the *Appendix*. It was was sent to Gauss in 1831, but it was lost in transit. The *Appendix* was sent a second time in January 1832 (Bonola 1912, 99–100).

Dated March 6, 1832, the letter that Gauss sent in reply to Farkas is one of the most famous ever penned in the history of mathematics. As we have seen, Gauss studied the parallels question, and he came to many of the same results as others had. The difference was that he had kept his results private. Thus, we are not surprised by what Gauss wrote to his old colleague from Göttingen.

> If I commenced by saying that I *am unable to praise this work* (by Johann), you would certainly be surprised for a moment. But I cannot say otherwise. To praise it, would be to praise myself. Indeed the whole contents of the work, the path taken by your son, the results to which he is led, coincide almost entirely with my meditations, which have occupied my mind partly for the last thirty or thirty-five years. So I remained quite stupefied. So far as my own work is concerned, of which up till now I have put little on paper, my intention was not to let it be published during my lifetime. Indeed the majority of people have not clear ideas upon the questions of which we are speaking, and I have found very few people who could regard with any special interest what I communicated to them on this subject. To be able to take such an interest it is first of all necessary to have devoted careful thought to the real nature of what is wanted and upon this matter almost all are most uncertain. On the other hand it was my idea to write down all this later so that at least it should not perish with me. It is therefore a pleasant surprise for me that I am spared this trouble, and I am very glad that it is just the son of my old friend, who take the precedence of me in such a remarkable manner. (Bonola 1912, 100)

Farkas was pleased with the letter and viewed it as an honor. János, however, did not. He was devastated. He initially suspected that his father had secretly informed Gauss of his work and now Gauss was using that communication to upstage him. This could not have been further from the truth, because Farkas was very proud of his son and wanted only the best for him. This we have seen in Farkas's letters.

Nonetheless, the event strained the relationship between the two, and it never fully healed. It took nearly 10 years before János eventually accepted the truth of the situation, but he would never come to fully trust Gauss. Scholars dispute whether this distrust was justified. Gauss did work on the question of parallels, but whether his results rose to the level of János' work is left to various interpretations (Bonola 1912, 101; Gray 2004, 54–55).

János's acceptance of the facts did not mean that the letter did not have lasting effects. He would never publish again, although he did continue mathematical research. Making matters worse was the fact that the *Appendix* was ignored by the mathematical community, and then in 1848 János discovered a German edition of a treatise written by a Russian mathematician. Again he initially believed that the work must have been stolen since the results were so similar. They both used Saccheri's definition of parallel and proved the same basic results. They both examined spherical geometry, discovered the equation for the angle of parallelism, and constructed the same geometrical objects. There were some differences. The Russian tended to be more analytical, while Bolyai tended to focus on making clear the distinction between those theorems that followed from the negation of the Parallel Postulate and those that can be proven without any kind of parallel assumption (Burton 1985, 555; Prékopa 2006, 19).

The Russian's name was Nicolai Ivanovich Lobachevski. He was born on December 1, 1792 in the Russian city of Nizhny Novgorod. He was the son of Ivan Maksimovich Lobachevski, a government clerk, and his wife, Praskovia Aleksandrovna Lobachevskaya. Ivan died when the boy was only 7, so without an income, Praskovia moved to Kazan. The city was remote, near the Siberian border, and it had a large Muslim population. The benefit to moving to the city was that the Russian government supported Kazan both financially and educationally in an effort to spread Russian culture to the population. With the aid of a government scholarship, Lobachevski attended school. He was a bright student but not always interested in his studies. His teachers recognized in him an ability for mathematics, so they worked with him and helped him graduate.

With a goal of studying medicine, Lobachevski entered Kazan University in 1807. The university also benefited from the government's policies. They recruited professors to Kazan from Europe with the goal of creating a top center of Russian learning. One of these new faculty members was Martin Bartels from Caroline College. Lobachevski came into contact with him and soon abandoned medicine for mathematics. In 1811 he received his master's degree in mathematics and physics, and two years later he joined the university faculty teaching courses in his master's fields and astronomy. In 1816, at the age of 33, Lobachevski was promoted to the rank of full professor (Burton 1985, 557; Boyer and Merzbach 1991, 520).

Bartels and the other mathematics faculty at the University of Kazan educated Lobachevski in the German tradition. This meant that geometry played an important role in his education. He carried this influence into his professional life, often teaching the subject. One day in 1823 he wrote an outline for his students. He noted for his class that no one to date had found a proof of the Parallel Postulate. Such a note provides evidence that he was thinking about the subject, and as with every other interested mathematician, he must have thought about proving it. Three years later he presented a paper at his university in which he elaborated many of the results that follow when the Parallel Postulate is assumed to be false. Then in 1829 he did something that Gauss would not do. Convinced that it was impossible to prove the Parallel Postulate, he published his research on parallels as a new system of geometry with the Hypothesis of the Acute Angle as a postulate. It appeared in the *Kazan Messenger*, and it was titled "On the Principles of Geometry." He realized that the results were not in line with the mathematical community. Nonetheless, he believed that the theorems that flowed from the new postulate set formed a consistent logical system. Lobachevski called his new system **imaginary geometry** (Boyer and Merzbach 1991, 520–521).

Gauss appears to have been correct concerning the Boeotians. When Lobachevski submitted his 1829 paper, the referee, the person assigned to read the work and comment on its value and correctness, did not understand Lobachevski's ideas and commented negatively. Nonetheless, the paper still went to publication. Reviews were not favorable. One mathematician suggested that Lobachevski had titled his piece incorrectly. Instead of *On the Principles of Geometry*, it should have been named either *A Satire on Geometry* or *A Caricature of Geometry*. Lobachevski was not discouraged and continued to publish his research on his new imaginary geometry in 1835 with the *New Foundations of Geometry*, written in Russian. In 1840 he completed his *Geometrical Investigations on the Theory of Parallels*, written in German (Rosenfeld 1988, 208–209; Boyer and Merzbach 1991, 521). In it Lobachevski opens by writing:

> In geometry I find certain imperfections which I hold to be the reason why this science, apart from transition into analytics, can as yet make no advance from that state in which it has come to us from Euclid.
>
> As belonging to these imperfections, I consider the obscurity in the fundamental concepts of the geometrical magnitudes and in the manner and method of representing the measuring of these magnitudes, and finally the momentous gap in the theory of parallels, to fill which all efforts of mathematics have been so far in vain. (Lobachevski 1914, 11)

All of the efforts of the past had not solved the problem of parallels. Some were close, but none were able to take the last step. Lobachevski would be the first mathematician to publicly accept and detail results that would rival Euclid and revolutionize geometry.

12.1 PARALLEL FUNDAMENTALS

To begin our survey of the geometric work of Lobachevski and Bolyai, we start by proving some basic facts about parallel lines. Using Lobachevski's diagram (Figure 12.1), let $\overline{AN}$ be parallel to $\overline{BY}$ and let $\overline{AB}$ be perpendicular to $\overline{BY}$. By Theorem 10.5.2 acute $\sphericalangle BAN$ has the property that if $\overline{AK}$ is in the interior of $\sphericalangle BAN$, it intersects $\overline{BY}$, but if $\overline{AK}$ is in the interior of $\sphericalangle NAM$, it will not meet $\overline{BY}$. The point A is said to have the **characteristic of parallelism** for $\overline{AN}$ and $\overline{BY}$ because $\sphericalangle BAN$ has these properties. We should note that there is a mirror image of this

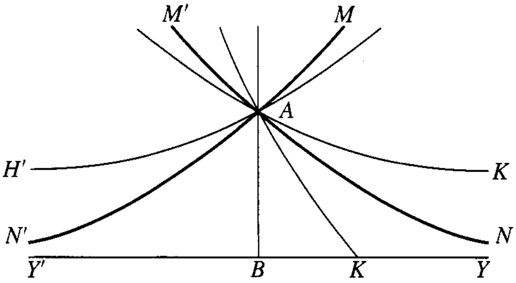

Figure 12.1 The parallel lines of Lobachevski.

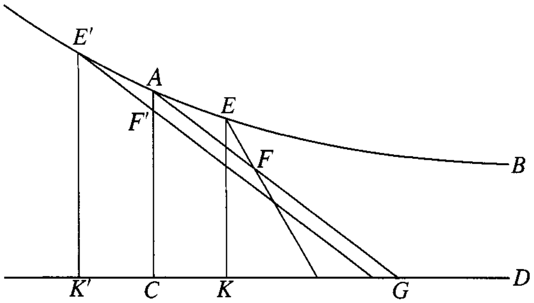
situation on the other side of $\overline{AB}$ and A is not the only point on $\overline{AN}$ that has the characteristic of parallelism.

■ **THEOREM 12.1.1** [*Theory of Parallels* 17, *Appendix* 2]

[HA] If $\overline{AB}$ is parallel to $\overline{CD}$, every point on $\overline{AB}$ has the characteristic of parallelism.



PROOF

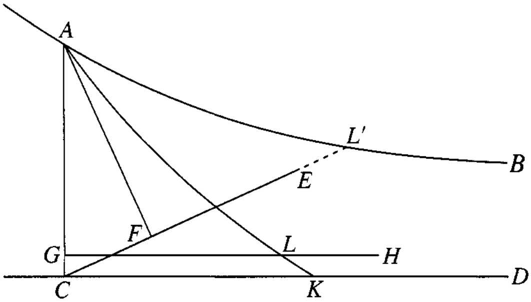
Let $\overline{AB}$ be parallel to $\overline{CD}$ and let A have the characteristic of parallelism for $\overline{AB}$ and $\overline{CD}$. Take E to the right of A in the diagram making $\sphericalangle CAE$ acute. Find K on $\overline{CD}$ so that $\overline{EK}$ is perpendicular to $\overline{CD}$. Pick F in the interior of $\sphericalangle BEK$ and join both $\overline{EF}$ and $\overline{AF}$. Since $\overline{AF}$ is in the interior of m$\sphericalangle CAB$, we may conclude that $\overline{AF}$ will intersect $\overline{CD}$ at some G when extended. This forms $\triangle ACG$, so by Pasch's Postulate (11.3.2), $\overline{EF}$ produced must meet $\overline{CD}$.

Next, let E' be on $\overline{AB}$ but on the other side of $\overline{AC}$ and let K' be on the $\overline{CD}$ produced such that $\overline{E'K'}$ is perpendicular to $\overline{CD}$. Choose F' on $\overline{AC}$. Since A has the characteristic of parallelism, we can find G on $\overline{CD}$ such that $\sphericalangle BAG \cong \sphericalangle AE'F'$. We now have $\triangle ACG$, in which $\overline{E'F'}$ enters through $\overline{AC}$. If $\overline{E'F'}$ intersects $\overline{AG}$, we would have a triangle with angle sum greater than two right angles because $\sphericalangle E'AG$ and $\sphericalangle AE'F'$ are supplements. Hence, it must be the case that $\overline{E'F'}$ can be extended to meet $\overline{CD}$. ■

In the next two theorems we prove that parallel lines under the new definition share some common characteristics with Euclid's parallel lines. The first result states that lines are parallel is a symmetric relation. Lobachevski's proof relies on a continuity argument.

■ **THEOREM 12.1.2** [*Theory of Parallels* 18, *Appendix* 6]

[HA] If $\overline{AB}$ is parallel to $\overline{CD}$, then $\overline{CD}$ is parallel to $\overline{AB}$.



PROOF

Suppose that $\overline{AB}$ is parallel to $\overline{CD}$ with $\overline{AC}$ perpendicular to $\overline{CD}$. Because $\overline{AB}$ and $\overline{CD}$ do not intersect, to prove that $\overline{CD}$ is parallel to $\overline{AC}$, it suffices to show that any line in the interior of $\sphericalangle ACD$ must intersect $\overline{AB}$. To do this, let $\overline{CE}$ form the acute $\sphericalangle ACE$ in the interior of $\sphericalangle ACD$. Construct a perpendicular to $\overline{CE}$ through A. Let F be its point of intersection with $\overline{CE}$. The result is right $\triangle AFC$ with $AC > AF$. Thus, we can find G on $\overline{AC}$ so that $\overline{AG} \cong \overline{AF}$. Now construct $\overline{GH}$ perpendicular to $\overline{AC}$ and rotate $BAFE$ with pivot A so that $\overline{AF}$ and $\overline{AG}$ line up. This is equivalent to taking K on $\overline{CD}$ such that

$$\sphericalangle GAK \cong \sphericalangle FAB.$$

We can find such a K since $\overline{AB}$ is parallel to $\overline{CD}$. Let L be the intersection of $\overline{AK}$ and $\overline{GH}$. Find L' on $\overline{CE}$ (produced if necessary) such that $\overline{FL'} \cong \overline{GL}$. Because $\overline{AG} \cong \overline{AF}$, $\sphericalangle AGL \cong \sphericalangle AFL'$, and $\overline{GL} \cong \overline{FL'}$, we conclude by SAS that

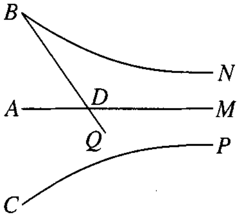
$$\triangle AGL \cong \triangle AFL'.$$

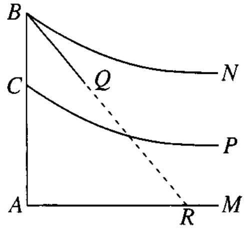
Hence, $\sphericalangle FAL' \cong \sphericalangle GAL$. Since $\sphericalangle GAL$ and $\sphericalangle GAK$ are the same angle, we conclude that $\sphericalangle FAL' \cong \sphericalangle FAB$. The only way for this to happen is if L' is on $\overline{AB}$. Therefore, $\overline{CD}$ is parallel to $\overline{AB}$. ■

Being parallel is not transitive, as noted in Exercise 2. The next theorem is as close as we can get.

■ **THEOREM 12.1.3** [*Theory of Parallels* 25]

[HA] If two distinct lines are parallel to a third, they are parallel to each other.





PROOF

Let both $\overline{BN}$ and $\overline{CP}$ be parallel to $\overline{AM}$ with C not on $\overline{BN}$. By Exercise 4, $\overline{BN}$ and $\overline{CP}$ do not intersect. We now have two cases to consider. First let $\overline{AM}$ be between $\overline{BN}$ and $\overline{CP}$. Take point Q and form $\sphericalangle NBQ$ toward $\overline{AM}$, so $\overline{BQ}$ and $\overline{AM}$ must intersect at some point D. Since $\overline{AM}$ is parallel to $\overline{CP}$ (Theorem 12.1.2), $\overline{DQ}$ will meet $\overline{CP}$ since all of the points of $\overline{AM}$ have the characteristic of parallelism (Theorem 12.1.1). Thus, $\overline{BN}$ is parallel to $\overline{CP}$.

Next let $\overline{AM}$ not be between the other two. Without loss of generalization we may assume that $\overline{CP}$ is between $\overline{BN}$ and $\overline{AM}$ and for clarification in the diagram assume that B, C, and A are collinear. Let $\overline{BQ}$ form an angle within $\sphericalangle NBA$. Since $\overline{BN}$ is parallel to $\overline{AM}$, we can produce $\overline{BQ}$ to intersect $\overline{AM}$ at some R. Now notice that $\overline{CP}$, $\overline{CA}$, and $\overline{AM}$ form an omega triangle (Definition 11.3.1). Since $\overline{BR}$ already intersects one of its sides, by Theorem 11.3.5, we conclude that $\overline{BQ}$ must intersect $\overline{CP}$. ■

The Angle of Parallelism

Let $\overline{AB}$ be perpendicular to $\overline{BY}$ and assume that $\overline{AN}$ is parallel to $\overline{BY}$ (Figure 12.2). Let $p = AB$. Since the measure of the angle of parallelism (page 351) is dependent only on the value of p, we will define

$$\Pi : [0, \infty) \to [0, \pi/2]$$

by

$$\Pi(p) = \begin{cases} \mathrm{m}\sphericalangle BAN, & p > 0 \\ \pi/2, & p = 0, \end{cases}$$

where we define $\Pi(0) = \pi/2$ because

$$\lim_{p \to 0+} \Pi(p) = \pi/2 \tag{12.1}$$

by Exercise 7. Furthermore, if we let H be a point and set $\alpha = \mathrm{m}\sphericalangle BAH$, we have:

- If $0 \leqslant \alpha < \Pi(p)$, the $\overline{AH}$ produced intersects $\overline{BY}$.
- If $\alpha = \Pi(p)$, then $\overline{AH}$ is parallel to $\overline{BY}$.
- If $\Pi(p) < \alpha \leqslant \pi/2$, then $\overline{AH}$ will not intersect $\overline{BY}$.

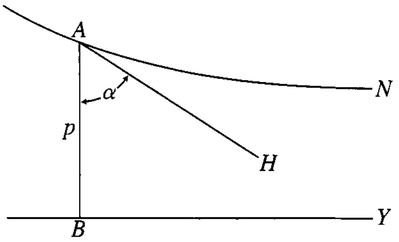


Figure 12.2 $\sphericalangle BAN$ is the angle of parallelism.

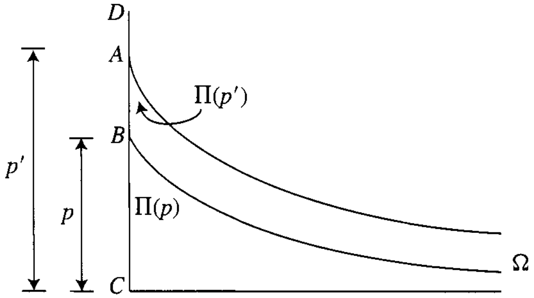
If $\alpha > \pi/2$, view the line as on the opposite side of $\overline{AB}$ and treat accordingly (Lobachevski 1914, 13–14). It is important to note that **HR** implies that $\Pi(p) = \pi/2$ for all p. However, because the work of Lobachevski and Bolyai focused only on the **HA** case, we assume this hypothesis for the rest of the chapter.

The function Π has many nice properties that we now prove. The proof of the first result uses omega triangles.

■ THEOREM 12.1.4

[**HA**] Π is a strictly decreasing function.



PROOF

Let $\overline{CD}$ be perpendicular to $\overline{C\Omega}$. Take A and B on $\overline{CD}$ and write $p = BC$ and $p' = AC$. To see that Π is strictly decreasing, suppose that $p < p'$. Remember that $\overline{A\Omega}$, $\overline{B\Omega}$, and $\overline{C\Omega}$ are all parallel to each other. Then $m\sphericalangle CB\Omega = \Pi(p)$ and $m\sphericalangle CA\Omega = \Pi(p')$. We observe that $\sphericalangle DA\Omega$ is exterior to $\triangle AB\Omega$. Therefore, by Theorem 11.3.6,

$$m\sphericalangle AB\Omega < m\sphericalangle DA\Omega.$$

This gives

$$\pi - m\sphericalangle AB\Omega > \pi - m\sphericalangle DA\Omega,$$

from which we see that $\Pi(p) > \Pi(p')$, so Π is strictly decreasing. ■

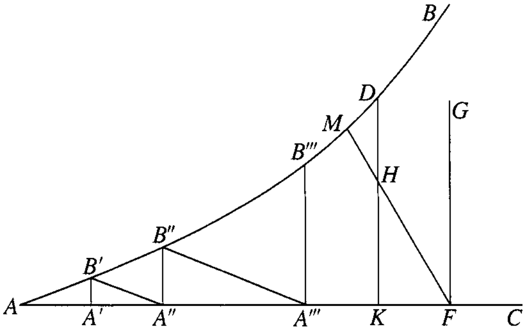
■ COROLLARY 12.1.5

[**HA**] Π is one-to-one.

By Theorem 10.5.2 we know that to every magnitude there is associated an angle of parallelism. The next theorem states that the converse is also true, so we now know that Π is a one-to-one correspondence.

■ THEOREM 12.1.6 [*Theory of Parallels* 23]

[**HA**] Π is onto.



PROOF

Take α such that $0 \leqslant \alpha \leqslant \pi/2$. We must find p so that $\Pi(p) = \alpha$. Let $\text{m}\sphericalangle BAC = \alpha$. Take an arbitrary point B' on $\overline{AB}$ and drop a perpendicular to $\overline{AC}$, meeting it in A'. Find A'' on $\overline{A'C}$ such that $\overline{A'A''} \cong \overline{AA'}$. At A'' erect a perpendicular that intersects $\overline{AB}$ at B''. Continuing this process, we will find $\overline{FG}$ that is perpendicular to $\overline{AC}$ but does not intersect the $\overline{AB}$ produced. We will prove this fact indirectly, so assume that no such perpendicular exists. Appealing to Theorem 10.4.5, we know that

$$\text{d}(AB'A'') = \text{d}(AB'A') + \text{d}(A''B'A').$$

Because $\triangle AB'A' \cong \triangle A''B'A'$ by SAS, $\text{d}(AB'A'') = 2\text{d}(AB'A')$. Therefore,

$$\text{d}(AB''A'') > 2\text{d}(AB'A')$$

by Theorem 10.4.5. Next find A''' on $\overline{AC}$ and B''' on $\overline{AB}$ such that $\overline{A''A'''}$ is congruent to $\overline{AA''}$ and $\overline{A'''B'''}$ is perpendicular to $\overline{AC}$. As before we have $\triangle AB''A'' \cong \triangle A'''B''A''$, and we conclude that

$$\text{d}(AB'''A''') > 2^2\text{d}(AB'A').$$

We can repeat this construction and find for each positive integer n an ordinary triangle with defect greater than $2^n\text{d}(AA'B')$. That is, we can find a triangle with angle sum less than $\pi - 2^n\text{d}(AA'B')$ for each n, which means that we can find a triangle with angle sum less than or equal to zero, which is impossible.

Without loss of generality we may assume that $\overline{FG}$ is the first perpendicular that does not intersect $\overline{AB}$. Its existence is guaranteed by an argument similar to that for the existence of Saccheri's limit (Theorem 10.5.2 and page 351). To prove that $\overline{AB}$ is parallel to $\overline{FG}$, it suffices to show that $\overline{FG}$ is parallel to $\overline{AB}$ (Theorem 12.1.2). To do this take H in the interior of $\sphericalangle AFG$. Choose K on $\overline{AC}$ so that $\overline{HK}$ is perpendicular to $\overline{AC}$. Since $\overline{FG}$ is the first not to intersect $\overline{AB}$, there exists D on $\overline{AB}$ where the $\overline{KH}$ produced intersects $\overline{AB}$. We obtain $\triangle AKD$. Since $\overline{FH}$ enters this triangle at $\overline{DK}$, it must exit through $\overline{AD}$ at some point M by Pasch's Postulate (11.3.2). Thus, $\overline{FG}$ is a parallel to $\overline{AB}$, and we may set $p = AF$. ■

All of this allows us to conclude that Π is also continuous (Wolfe 1945, 76–77; Lobachevski 1914, 21). Assuming **HR**, Π is a constant function, so it is continuous. To prove the result under **HA**, suppose that Π is not continuous at p_0. This means that

$$\Pi(p_0) \neq \lim_{p \to p_0} \Pi(p),$$

and this means that one of the one-sided limits does not equal $\Pi(p_0)$. Suppose that it is $p \to p_0^-$. Then there exists $\epsilon > 0$ such that for all x where $0 < x < p_0$,

$$\Pi(x) - \Pi(p_0) > \epsilon.$$

From this we conclude that no angle measure θ such that $\Pi(p_0) < \theta < \Pi(p_0) + \epsilon$ corresponds to a segment length since Π is strictly decreasing. This contradicts Theorem 12.1.6. Therefore, we have:

■ **THEOREM 12.1.7**

Π is continuous.

Exercises

1. Let $\overline{AX}$ be parallel to $\overline{BY}$ and $\overline{BY}$ be parallel to $\overline{CZ}$. Is it possible for $\overline{AD}$ to not intersect $\overline{BY}$ but intersect $\overline{CZ}$. Explain.

2. Is it possible for l to be parallel to m, m parallel to n, but l not parallel to n?

3. Use omega triangles to prove Theorem 12.1.2 and reprove the first case of the proof for Theorem 12.1.3.

4. Prove that $\overline{BN}$ and $\overline{CP}$ do not intersect in the proof of Theorem 12.1.3.

5. Generalize the definition of two lines being parallel to the three dimensions.

6. Let l, m, and n be distinct lines in three dimensions. Assume that l and m are parallel to n in space. Using the definition from Exercise 5, demonstrate that n is parallel to both l and m and l is parallel to m.

7. Show $\lim_{p \to 0^+} \Pi(p) = \pi/2$.

8. Explain why AA (Theorem 11.3.8) implies that Π is not a constant function.

9. True or false: There exists a positive real number p such that $\Pi(p) = \pi/2$ if and only if **HR**. Explain your reasoning.

10. Let l be a line and P a point off l. True or false: There exists exactly one line n through P that is parallel to l if and only if **HR**. Explain your reasoning.

11. Let A not be on l. Let $\overline{AN}$ and $\overline{AN'}$ both be parallel to l as in Figure 12.1. Prove that the angle bisector of $\sphericalangle N'AN$ is perpendicular to l.

12. Suppose that X and Y are on the same side of $\overline{AB}$. Let $\sphericalangle BAX$ and $\sphericalangle ABY$ be supplementary. Prove that $\overline{AX}$ is not parallel to $\overline{BY}$ and that the two lines do not intersect.

12.2 HOROCYCLES

In 1804, Farkas Bolyai sent Gauss what he thought was a proof of the Parallel Postulate. Gauss showed him his error in a later letter, but Farkas was nonetheless still hopeful of finding a proof and continued to study the subject (Kline 1972, 878). One of his attempts was his proof that the Parallel Postulate follows from the assumption

$$\text{three points that are not collinear lie on a circle.} \tag{12.2}$$

To prove this, take $\overline{AB}$ and points A' and B' on the same side of $\overline{AB}$ such that $\overline{BB'}$ and $\overline{AB}$ are perpendicular and $\sphericalangle BAA'$ is acute (Figure 12.3). We must show that $\overline{AA'}$ and $\overline{BB'}$ intersect on the same side of $\overline{AB}$ as both A' and B'. Take any point M on $\overline{AB}$. Find M' on the opposite side of $\overline{AA'}$ such that $\overline{AA'}$ is the perpendicular bisector of $\overline{MM'}$. Similarly, let M'' be on $\overline{AB}$ produced so that $\overline{BB'}$ is the perpendicular bisector of $\overline{MM''}$. We observe that M, M', and M'' are not collinear. Hence, they lie on a circle by Proposition 12.2. Both $\overline{AA'}$ and $\overline{BB'}$ are concurrent with radii of the circle, so they must intersect at the circle's center (Bonola 1912, 61).

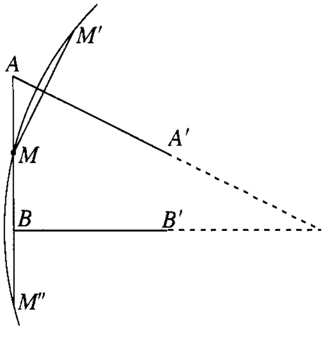


Figure 12.3 Farkas Bolyai's proof of the Parallel Postulate.

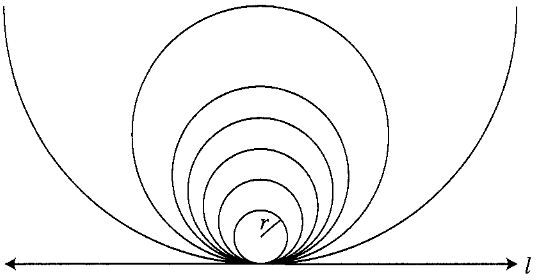

Figure 12.4 A circle with radius approaching infinity.

The problem with Farkas Bolyai's approach is that Proposition 12.2 is equivalent to the Parallel Postulate (Exercise 1). However, this result did inspire a student of Gauss by the name of Friedrich Ludwig Wachter. He also attempted to prove the Parallel Postulate. Despite believing otherwise, Wachter was not successful. In a letter written in 1816 to Gauss he described his efforts. He wrote concerning what he believed would happen when the radius of a sphere was allowed to approach infinity. Take a circle with radius r and let $r \to \infty$ as illustrated in Figure 12.4. The limit of the circles l is called the **circle with infinite radius**. If **HR** is assumed, l is a line; otherwise, l is a nonstraight curve. Now rotate the original circle about its diameter, forming a sphere. As $r \to \infty$ the sphere approaches the surface formed by revolving l about a point. When **HR** is assumed, the resulting surface is a plane, but under **HA** it will be a **sphere with infinite radius**. Wachter observed that even when working under the Hypothesis of the Acute Angle, **HR** held on the surface of rotation (Bonola 1912, 62–63). In this section we define a curve that is Wachter's circle with infinite radius. Later we consider his infinite sphere. Both of these played an important role in the work of Lobachevski and Bolyai.

Fundamentals

We begin with some required terminology. Take two parallel lines $\overline{A\Omega}$ and $\overline{B\Omega}$, where Ω is an ideal point (Figure 12.5). Join $\overline{AB}$. Construct the bisectors to $\sphericalangle BA\Omega$ and $\sphericalangle AB\Omega$. These two bisectors meet in a point E (Exercise 11). If we drop a perpendicular from E to $\overline{AB}$ intersecting it at F, then

$$\triangle AFE \cong \triangle ACE \text{ and } \triangle BFE \cong \triangle BDE$$

by AAS. Thus, $\overline{CE} \cong \overline{DE}$ because $\overline{CE} \cong \overline{FE}$ and $\overline{FE} \cong \overline{DE}$. Let $\overline{E\Omega}$ be parallel to both $\overline{A\Omega}$ and $\overline{B\Omega}$ (Exercise 10). This line is called the **line of symmetry** between the parallels $\overline{A\Omega}$ and $\overline{B\Omega}$. We note the following (Exercise 13):

- The line of symmetry bisects $\sphericalangle DEC$.
- The line of symmetry is equidistant between its two parallel lines.

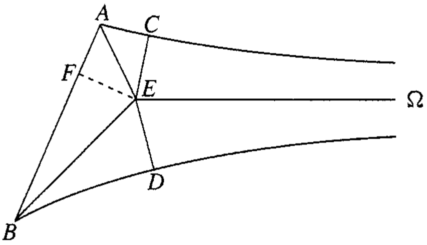

Figure 12.5 $\overline{E\Omega}$ is the line of symmetry between $\overline{A\Omega}$ and $\overline{B\Omega}$.

Furthermore, if we join C and D, the angles that $\overline{CD}$ makes with $\overline{A\Omega}$ and $\overline{B\Omega}$ are congruent (Exercise 12). We have a name for this (Wolfe 1945, 110–113).

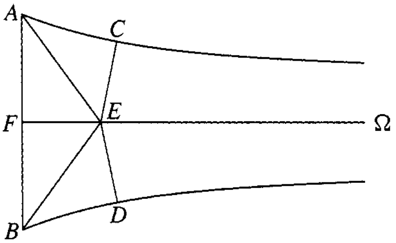
■ **DEFINITION 12.2.1** [*Appendix* 8]

If $\overline{C\Omega}$ is parallel to $\overline{D\Omega}$ and $\sphericalangle CD\Omega$ is congruent to $\sphericalangle DC\Omega$, the point C **corresponds** to the point D.

We now prove two basic results about corresponding points. The first involves finding the line of symmetry. The second states that given a point on one of two parallel lines, there is a unique point on the second parallel that corresponds to the given point.

■ **THEOREM 12.2.2**

[HA] If two points on different parallel lines correspond, the line of symmetry between the parallel lines is the perpendicular bisector of the segment joining the two points.

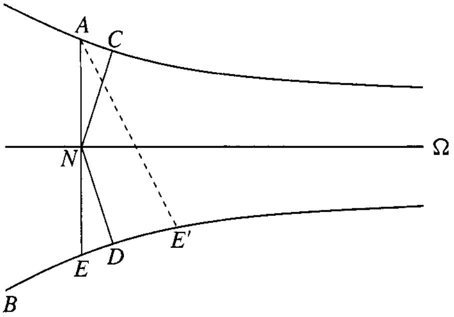


PROOF

Let $\overline{A\Omega}$ be parallel to $\overline{B\Omega}$ and suppose that A corresponds to B. Join $\overline{AB}$. Bisect $\sphericalangle BA\Omega$ and $\sphericalangle AB\Omega$ and let E be the intersection of the bisectors. Then $\overline{E\Omega}$ is the line of symmetry between $A\Omega$ and $B\Omega$. Extend it to intersect $\overline{AB}$ at F. Since A corresponds to B, $\sphericalangle BAE \cong \sphericalangle ABE$, and then $\overline{AE} \cong \overline{BE}$. Since $\overline{E\Omega}$ is the line of symmetry for the parallels, $\sphericalangle CE\Omega \cong \sphericalangle DE\Omega$. Thus, $\sphericalangle AEF \cong \sphericalangle BEF$. We now have $\triangle AFE \cong \triangle BFE$ by ASA. Therefore, $\overline{AF} \cong \overline{FB}$ and $\overline{F\Omega}$ is perpendicular to $\overline{AB}$ because $\sphericalangle AFE \cong \sphericalangle BFE$. ■

■ THEOREM 12.2.3

[HA] Given two parallel lines and any point on one of them, there exists exactly one point on the other line that corresponds to the first point.



PROOF

Let $\overline{A\Omega}$ and $\overline{B\Omega}$ have line of symmetry $\overline{N\Omega}$. Let N be chosen so that $\overline{AN}$ is perpendicular to $\overline{N\Omega}$. From N construct $\overline{NC}$ perpendicular to $\overline{A\Omega}$ at C and $\overline{ND}$ perpendicular to $\overline{B\Omega}$ at D. Because $\overline{N\Omega}$ is the line of symmetry for $\overline{A\Omega}$ and $\overline{B\Omega}$, we have $\overline{NC} \cong \overline{ND}$. Finally, find E on $\overline{B\Omega}$ so that E is between B and D and $\overline{AC} \cong \overline{ED}$. Since $\triangle ACN \cong \triangle EDN$ by SAS, we see that A, N, and E are collinear (Theorem 5.3.8) and

$$\sphericalangle EAC \cong \sphericalangle AED.$$

That is, A corresponds to E.

To see that the point E is unique, suppose that A also corresponds to the point E' on $\overline{B\Omega}$. This means that

$$\sphericalangle AE'\Omega \cong \sphericalangle E'A\Omega.$$

We now examine the angle sum of $\triangle AEE'$. Since

$$\mathrm{m}\sphericalangle AE'E = \pi - \mathrm{m}\sphericalangle AE'\Omega$$

and

$$\mathrm{m}\sphericalangle AEE' = \mathrm{m}\sphericalangle EAE' + \mathrm{m}\sphericalangle E'A\Omega,$$

we find that

$$\mathrm{m}\sphericalangle EAE' + \mathrm{m}\sphericalangle AEE' + \mathrm{m}\sphericalangle AE'E = 2\mathrm{m}\sphericalangle EAE' + \pi.$$

This contradicts the Saccheri-Legendre Theorem (11.2.7). ■

We are now ready to formally define the sphere of infinite radius. Bolyai did not give this curve a name, so we use Lobachevski's terminology.

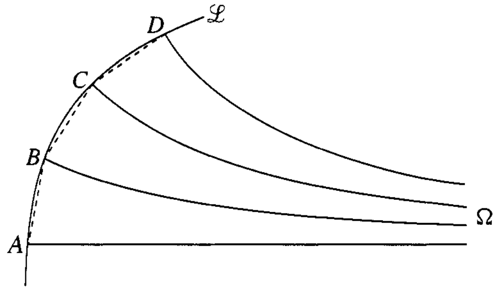


Figure 12.6 The horocycle $\mathscr{L}$ with corresponding points A, B, C, and D.

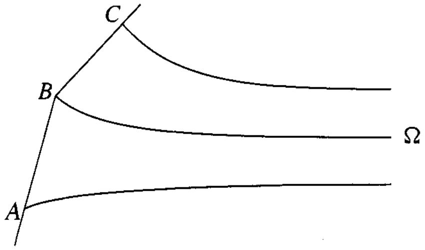
DEFINITION 12.2.4 [*Theory of Parallels* 31, *Appendix* 11]

Fix $\overline{A\Omega}$. The locus of all points B such that $\overline{B\Omega}$ is parallel to $\overline{A\Omega}$ and B corresponds to A is called a **horocycle** (or **boundary line**). The segment $\overline{A\Omega}$ is called the **axis** of the horocycle.

If we assume **HR**, the horocycle is a line. This is because when A and B are corresponding points on two parallel lines, they form interior angles on the same side that are congruent and supplementary. However, when we assume **HA**, the horocycle becomes a curve (Figure 12.6). This is the consequence of the next theorem.

THEOREM 12.2.5

[HA] If three points A, B, and C lie one on each of three mutually parallel lines such that A corresponds to B and B corresponds to C, the three points are not collinear.



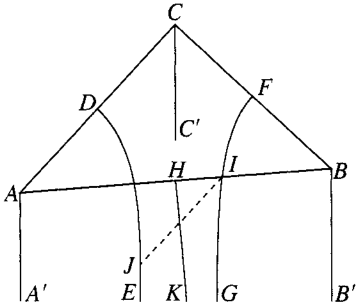
PROOF

Let A, B, and C be on distinct parallel lines through ideal point Ω. Let $\sphericalangle BA\Omega \cong \sphericalangle AB\Omega$ and $\sphericalangle CB\Omega \cong \sphericalangle BC\Omega$. Assume that A, B, and C are collinear. Then, $\sphericalangle AB\Omega$ and $\sphericalangle CB\Omega$ are supplementary. Hence, $\sphericalangle BA\Omega$ and $\sphericalangle BC\Omega$ are supplementary. This is impossible because we would have the angle sum of $\triangle AC\Omega$ at least as great as two right angles, so we conclude that A, B, and C cannot be collinear. ■

Not only is a horocycle $\mathcal{L}$ curved under **HA**, but any two points on $\mathcal{L}$ must correspond. This means that if a line drawn at a point on $\mathcal{L}$ is parallel to the defining axis of the horocycle, that line can be treated as the axis of the horocycle. For this reason we call every such line an **axis**. All of this follows from the next proposition.

■ **THEOREM 12.2.6** [*Theory of Parallels* **30**, *Appendix* **10**]

[HA] If three points A, B, and C lie one on each of three parallel lines, where A corresponds to C and B corresponds to C, A must correspond to B.



PROOF

Suppose that $\overline{AA'}$, $\overline{BB'}$, and $\overline{CC'}$ are parallel to each other with A and B corresponding with point C. Let $\overline{DE}$ be the line of symmetry between $\overline{AA'}$ and $\overline{CC'}$ and $\overline{FG}$ the line of symmetry between $\overline{CC'}$ and $\overline{BB'}$. Let $\overline{HK}$ be the perpendicular bisector of $\overline{AB}$ with H on $\overline{AB}$. We know that the two lines of symmetry are parallel to themselves and the three given lines (Theorem 12.1.3). Moreover, $\overline{HK}$ is parallel to $\overline{FG}$. To see this, let I be the intersection of $\overline{FG}$ and $\overline{AB}$ and let $\overline{IJ}$ be in the interior of $\sphericalangle HIG$. Since $\overline{DE}$ and $\overline{FG}$ are parallel, we may take J on $\overline{DE}$. Therefore, by Pasch's Postulate, $\overline{HK}$ must intersect $\overline{IJ}$. From this we may conclude that $\overline{HK}$ is parallel to both $\overline{AA'}$ and $\overline{BB'}$. Since $\overline{HK}$ is the perpendicular bisector to $\overline{AB}$, we have that $\sphericalangle A'AH$ is congruent to $m\sphericalangle B'BH$ because both have measure $\Pi(AH)$. Hence, the points A and B correspond to each other. ■

Concentric Horocycles

Let A be on horocycle $\mathcal{L}$ with axis $\overline{A\Omega}$ in a plane Λ. Let B be any other point on $\mathcal{L}$. By Definition 12.2.4, A corresponds with B on $\mathcal{L}$. Taking M to be the midpoint of $\overline{AB}$ implies that $\overline{M\Omega}$ is the line of symmetry between $\overline{A\Omega}$ and $\overline{B\Omega}$ and meets $\overline{AB}$ in a right angle (Theorem 12.2.2). Therefore, $m\sphericalangle MB\Omega = \Pi(AB/2)$, so we may describe $\mathcal{L}$ by

$$\mathcal{L} = \{X \in \Lambda : m\sphericalangle AX\Omega = \Pi(AX/2)\}. \tag{12.3}$$

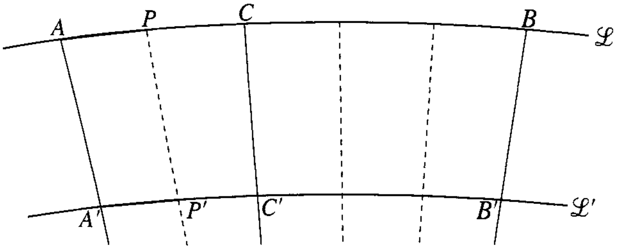
Furthermore, since all of the points on a horocycle correspond to each other, any of the parallels at a given point along the curve could have been chosen as the axis upon which to define $\mathcal{L}$. This means that the curvature of the horocycle is constant at every point. In fact, since the horocycle is defined with Π, all horocycles have the same curvature, allowing us to conclude that any two are congruent. Therefore, if two horocycles in a plane have a common axis, they will share all of their axes and the two horocycles will be equidistant as measured along them. Such a pair of horocycles are called **concentric**. Suppose that $\mathscr{L}$ and $\mathscr{L}'$ are concentric with A on $\mathscr{L}$ and B on $\mathscr{L}'$. If B is between A and the ideal point Ω on a common axis, we say that $\mathscr{L}$ is the **outer horocycle** with respect to $\mathscr{L}'$.

In concentric horocycles a pair of axes will intercept arcs that have lengths that depend only on the distance that separates the horocycles. To prove this, we need two lemmas.

■ LEMMA 12.2.7

Let $\mathscr{L}$ and $\mathscr{L}'$ be concentric horocycles. Take A, B, and C on $\mathscr{L}$ and A', B', and C' on $\mathscr{L}'$ such that $\overline{AA'}$, $\overline{BB'}$, and $\overline{CC'}$ are common axes. If $\overset{\frown}{AB}$ and $\overset{\frown}{AC}$ are commensurable, then

$$\frac{\mathrm{m}\overset{\frown}{A'C'}}{\mathrm{m}\overset{\frown}{AC}} = \frac{\mathrm{m}\overset{\frown}{A'B'}}{\mathrm{m}\overset{\frown}{AB}}.$$



PROOF

We assume that the lengths of arcs of a horocycle are additive and we measure the arcs by measuring their intercepted line segments. Let r and s be positive integers such that

$$\mathrm{m}\overset{\frown}{AC} = r(\mathrm{m}\overset{\frown}{AP}) \text{ and } \mathrm{m}\overset{\frown}{AB} = s(\mathrm{m}\overset{\frown}{AP}),$$

where P is some point on $\mathscr{L}$. In the diagram, $r = 2$ and $s = 5$. Without loss of generality, P is on $\overset{\frown}{AC}$. Now join $\overline{AC}$ and $\overline{A'C'}$. Notice that P is the midpoint of $\overset{\frown}{AC}$. Draw the axis to $\mathscr{L}$ at P and let it intersect $\mathscr{L}'$ at P'. Therefore, $\overline{PP'}$ is perpendicular to $\overline{AC}$. Since A corresponds to C and A' corresponds to C', $\sphericalangle A'AC \cong \sphericalangle C'CA$ and $\sphericalangle AA'C' \cong \sphericalangle CC'A'$. Finally, $\overline{AA'} \cong \overline{CC'}$ since the horocycles are concentric. Hence, $APP'A' \cong CPP'C'$. From this we conclude that $\overset{\frown}{A'P'} \cong \overset{\frown}{P'C'}$, so $\mathrm{m}\overset{\frown}{A'P'} = \mathrm{m}\overset{\frown}{P'C'}$ and

$$\mathrm{m}\overset{\frown}{A'C'} = r(\mathrm{m}\overset{\frown}{A'P'}).$$

Similarly, $\mathrm{m}\overset{\frown}{A'B'} = s(\mathrm{m}\overset{\frown}{A'P'})$. Since this argument generalizes to all positive integers r and s, we conclude that $\mathrm{m}\overset{\frown}{A'C'}/\mathrm{m}\overset{\frown}{AC} = \mathrm{m}\overset{\frown}{A'B'}/\mathrm{m}\overset{\frown}{AB}$. ■

The second lemma is needed here and in a future application.

■ **LEMMA 12.2.8**

Let f be a continuous, positive-valued function such that $f(1) < 1$ and

$$f(nx) = [f(x)]^n$$

for every $x > 0$ and positive integer n. Then there exists $k > 0$ such that $f(x) = e^{-kx}$ for all $x > 0$.

PROOF

Let $x > 0$ and take positive integers r and s. Observe that

$$f\left(\frac{r}{s}x\right) = f\left(r\frac{x}{s}\right) = \left[f\left(\frac{x}{s}\right)\right]^r$$

and

$$\left[f\left(\frac{x}{s}\right)\right]^s = f\left(s\frac{x}{s}\right) = f(x).$$

Therefore,

$$f\left(\frac{r}{s}x\right) = \left[f\left(\frac{x}{s}\right)\right]^r = \left[f\left(\frac{x}{s}\right)^s\right]^{r/s} = [f(x)]^{r/s}. \tag{12.4}$$

Now let $a > 0$ be a real number. There exist positive rational numbers $q_1, q_2, q_3, \ldots$ such that

$$\lim_{i\to\infty} q_i = a.$$

By Equation 12.4 we know that

$$f(q_i x) = [f(x)]^{q_i}$$

for all $i = 1, 2, 3, \ldots$. Therefore, since f is continuous,

$$f(ax) = \lim_{i\to\infty} f(q_i x) = \lim_{i\to\infty} [f(x)]^{q_i} = [f(x)]^a.$$

Finally, choose $k > 0$ so that $f(1) = e^{-k}$. Then

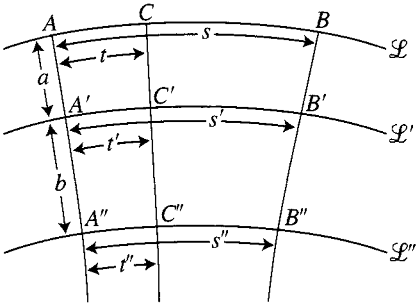
$$f(x) = [f(1)]^x = e^{-kx}. \blacksquare$$

We can now prove the main result.

■ **THEOREM 12.2.9** [*Theory of Parallels* 33]

Given concentric horocycles $\mathcal{L}$ and $\mathcal{L}'$ such that $\mathcal{L}$ is outer with respect to $\mathcal{L}'$, there exists $k > 0$ such that for all $\overline{AA'}$ and $\overline{BB'}$ that are shared axes of $\mathcal{L}$ and $\mathcal{L}'$ with A and B on $\mathcal{L}$ and A' and B' on $\mathcal{L}'$,

$$\mathrm{m}\widehat{A'B'} = \mathrm{m}\widehat{AB} \cdot e^{-k(AA')}.$$



PROOF

Let $\mathcal{L}''$ be a third horocycle concentric with $\mathcal{L}$ and $\mathcal{L}''$. Take any C on $\widehat{AB}$ and let the axis through C intersect $\mathcal{L}'$ at C' and $\mathcal{L}''$ at C''. Make the following assignments:

$$s = \mathrm{m}\widehat{AB}, s' = \mathrm{m}\widehat{A'B'}, s'' = \mathrm{m}\widehat{A''B''}$$

and

$$t = \mathrm{m}\widehat{AC}, t' = \mathrm{m}\widehat{A'C'}, t'' = \mathrm{m}\widehat{A''C''}.$$

Assume that s and t are commensurable. Since the horocycles are concentric, we know by Lemma 12.2.7 that

$$\frac{t'}{t} = \frac{s'}{s}, \frac{t''}{t'} = \frac{s''}{s'}, \text{ and } \frac{t''}{t} = \frac{s''}{s}.$$

Since these ratios remain constant, provided that the distance between the horocycles remains constant, we conclude that we can define a function $f(x)$ that equals the value of the ratio of the smaller arc to the larger one when the distance between the horocycles is x. Based on the above, we have

$$f(a) = \frac{s'}{s}, f(b) = \frac{s''}{s'}, \text{ and } f(a+b) = \frac{s''}{s}.$$

Therefore,

$$f(a)f(b) = \frac{s'}{s}\frac{s''}{s'} = \frac{s''}{s} = f(a+b).$$

Since a and b were chosen arbitrarily, we conclude that for all $x > 0$ and positive integers n,

$$\begin{aligned} f(nx) &= f([n-1]x + x) \\ &= f([n-1]x)f(x) \\ &= f([n-2]x)[f(x)]^2 \\ &\vdots \\ &= [f(x)]^n. \end{aligned}$$

Since f is certainly a continuous function and $f(x) < 1$, Lemma 12.2.8 allows us to conclude that for some $k > 0$, $f(x) = e^{-kx}$ for every $x > 0$. Hence,

$$e^{-k(AA')} = f(AA') = \mathrm{m}\widehat{A'B'}/\mathrm{m}\widehat{AB}. \blacksquare$$

Exercises

1. Prove that the Parallel Postulate implies that three points determine a circle.

2. Show that Theorem 12.2.3 also holds for **HR**.

3. Prove: If $\overline{AB}$ is parallel to $\overline{CD}$, $\sphericalangle CAB \cong \sphericalangle ACD$, and $\overline{EF}$ is the perpendicular bisector of $\overline{AC}$, then $\overline{EF}$ is parallel to both $\overline{AB}$ and $\overline{CD}$.

4. Prove:
   (a) If perpendiculars are drawn at the midpoints of the sides of a triangle and two of them are parallel, all three are parallel.
   (b) If perpendiculars are drawn at the midpoints of the sides of a triangle such that no two are parallel but they do not intersect each other, they are all perpendicular to the same line.

5. In a plane, how many horocycles pass through two given points? Explain.

6. Prove that a horocycle is determined uniquely by three distinct points.

7. Describe a mechanical device that could be used to draw a horocycle.

8. Let $\overline{A\Omega}$ be an axis of horocycle $\mathscr{L}$. Show that if $\overline{AT}$ is perpendicular to $\overline{A\Omega}$, then $\overline{AT}$ is tangent to $\mathscr{L}$. Is the converse true?

9. If a horocycle is revolved about any two of its axes, explain why the resulting surfaces are congruent. Are the two surfaces the same surface?

10. Let $\overline{A\Omega}$ be parallel to $\overline{B\Omega}$. Let C be a point not on either of these two parallel lines. Prove that there exists a line through C parallel to both $\overline{A\Omega}$ and $\overline{B\Omega}$.

11. In Figure 12.5, prove that the bisectors of $\sphericalangle BA\Omega$ and $\sphericalangle AB\Omega$ intersect in E.

12. Show that C and D are corresponding points in Figure 12.5.

13. Let n be the line of symmetry between l and m. There are two ways to interpret that n is equidistant between l and m.
    (a) Let A be on l and find B on n such that $\overline{AB}$ is perpendicular to l. Next find C on m such that $\overline{BC}$ is perpendicular to m. Show that $\overline{AB} \cong \overline{BC}$.
    (b) Let B be on n. Find A on l and C on m such that $\overline{AB}$ and $\overline{BC}$ are perpendicular to n. Prove that $\overline{AB} \cong \overline{BC}$.

14. Prove that the line of symmetry between two parallel lines is unique.

15. Let $\mathscr{L}$ and $\mathscr{L}'$ be concentric horocycles. Let A and B be on $\mathscr{L}$ and A' and B' be on $\mathscr{L}'$ such that $\overline{AA'}$ and $\overline{BB'}$ are common axes. Prove that if $\mathscr{L}$ is the outer horocycle with respect to $\mathscr{L}'$, then $AB > A'B'$.

16. Show that the area enclosed by two horocycles and two common axes is proportional to the distance between the horocycles. (*Hint:* First determine how to measure this area.)

17. Assume **HR**. Let $\overset{\frown}{AB}$, $\overset{\frown}{A'B'}$, and $\overset{\frown}{A''B''}$ be on concentric circles such that $\overline{AA'A''}$ and $\overline{BB'B''}$ are common radii and $\overline{AA'} \cong \overline{A'A''}$. Show that

$$\frac{\mathrm{m}\overset{\frown}{AB}}{\mathrm{m}\overset{\frown}{A'B'}} \neq \frac{\mathrm{m}\overset{\frown}{A'B'}}{\mathrm{m}\overset{\frown}{A''B''}}.$$

18. Let f and g be real-valued, continuous functions. Answer the following and justify your responses.
   (a) If $f(n) = g(n)$ for all integers n, does $f = g$?
   (b) If $f(x) = g(x)$ for all rational numbers x, does $f = g$?
   (c) If $f(x) = g(x)$ for all irrational numbers x, does $f = g$?

19. Given $\overline{AB}$ and $k > 0$. The set of all points P such that the perpendicular distance from P to $\overline{AB}$ equals k is called an **equidistant curve**. $\overline{AB}$ is called the **baseline**, and any segment between the curve and the baseline that is perpendicular to the baseline is an **axis**.
   (a) Explain why each equidistant curve has two **branches**, one "below" the baseline and one "above."
   (b) Draw an equidistant curve assuming **HR** and then assuming **HA**.
   (c) Assuming **HA**, draw two equidistant curves to $\overline{AB}$, one with distance k_1 and the other with distance $k_2 > k_1$.

20. Prove the following about equidistant curves:
   (a) A line intersects an equidistant curve at most twice.
   (b) A line that intersects an equidistant curve at P and is perpendicular to the axis at P is tangent to the curve.

21. Let l be a line and $\mathscr{C}$ an equidistant curve to l. Let $\overline{AB}$ be an axis with A on $\mathscr{C}$ and B on l. Prove that for any two distinct points C and D on $\mathscr{C}$ such that $\overline{CA} \cong \overline{AD}$, there exist C' and D' on l such that $\sphericalangle C'CA \cong \sphericalangle D'DA$ and $\sphericalangle CC'B \cong \sphericalangle DD'B$. Can the construction be redone so that $\sphericalangle C'CA \cong \sphericalangle CC'B$?

22. Conjecture why the horocycle is viewed as a circle of infinite radius.

12.3 THE SURFACE OF A SPHERE

Thus far our introduction to non-Euclidean geometry has involved references to spheres. Lambert conjectured that his new geometry could be interpreted as existing on the surface of a sphere with an imaginary radius. Wachter wrote to Gauss about his sphere of infinite radius. In each of these cases, the surface of the sphere is what was important, so in this section we survey some of the results concerning this surface in Euclidean space. These results will later be generalized to help us understand the geometry of the Hypothesis of the Acute Angle.

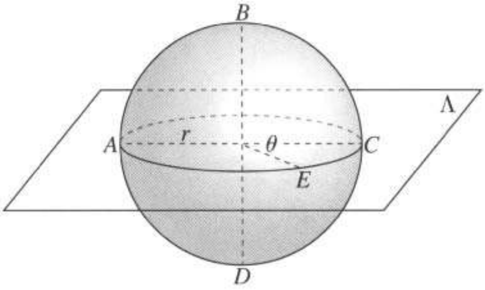


Figure 12.7 The sphere $ABCD$ cut by plane Λ forming a great circle.

The Area of a Triangle

Fix a sphere of radius r. The points of the geometry will be standard points on the surface of this sphere. The lines will be **great circles**. These are the circles formed by the intersection of the sphere with a plane that contains the sphere's center, as in Figure 12.7. A line segment in this geometry will be an arc of a great circle. Hence, the length of a segment is given by

$$\text{arc length} = \text{sphere's radius} \times \text{arc's central angle}, \tag{12.5}$$

where all angles are measured in radians. For example, in Figure 12.7 the length of $\overset{\frown}{EC}$ is $r\theta$.

As lines in the plane can be used to construct angles and triangles, the same is true for great circles on the surface of the sphere. Let Λ and K be two planes that cut the sphere, forming two great circles, as in Figure 12.8. Suppose that B is a point of intersection of the two great circles and assume that the plane A_1BC_1 is tangent to the sphere at B. We will denote the **spherical angle** formed by points A, B, and C by our usual angle notation, and its measure will be defined as the measure of $\sphericalangle A_1BC_1$. In some cases three great circles will meet to form a triangle. Such a figure is called a

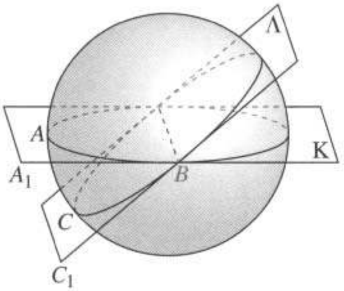

Figure 12.8 The measure of $\sphericalangle ABC$ equals the measure of $\sphericalangle A_1BC_1$.

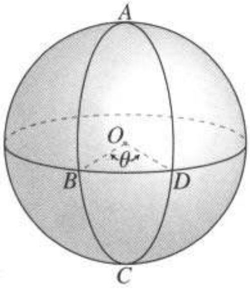

Figure 12.9 The lune $ABCD$.

spherical triangle, and again we will not change notation. The type of triangle will be clear from context. As opposed to the situation with triangles constructed under **HA**, triangles on the surface of a sphere have a positive angle excess. This means that for spherical $\triangle ABC$,

$$\text{angle excess} = (\mathrm{m}\sphericalangle A + \mathrm{m}\sphericalangle B + \mathrm{m}\sphericalangle C) - \pi > 0.$$

The proposition that allows us to conclude this is called **Girard's Theorem.** Albert Girard was Flemish and lived from 1590 to 1633. He is noted for his early promotion of algebraic symbolism, and he was the first to formulate the Fundamental Theorem of Algebra (Boyer and Merzbach 1991, 303, 319; Burton 1985, 512). His work in trigonometry led him to prove the theorem that bears his name. The proof given below, however, is due to Euler (Rosenfeld 1988, 31–32). He proved it using lunes. A **lune** is the region on the surface of a sphere that lies between two great circles. (Compare this definition with that of Exercise 3 in Section 4.3.) The great circles intersect at the endpoints of a diameter of the sphere. These two points are called **antipodal.**

Let us find the area of a lune on a sphere with center O and radius r. Suppose that A, B, and C lie on a great circle and A, D, and C lie on another great circle (Figure 12.9). Let $\theta = \mathrm{m}\sphericalangle BOD$. The ratio of the area of the lune swept out by θ to the surface area of the sphere is $\theta/2\pi$. Thus,

$$\text{area}(\text{lune } ABCD) = \frac{\theta}{2\pi} \cdot 4\pi r^2 = 2\theta r^2$$

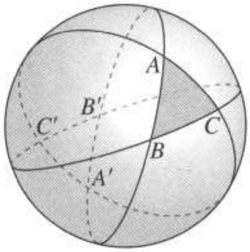
because the surface area of the sphere is $4\pi r^2$. On the unit sphere the equation simplifies to

$$\text{area}(\text{lune } ABCD) = 2\theta.$$

This is what is needed in Euler's proof.

■ THEOREM 12.3.1 [Girard]

The area of a spherical triangle equals its angle excess.



PROOF

Begin by choosing a sphere with unit radius. Let $\triangle ABC$ be on the sphere's surface. Let A', B', and C' be antipodal, respectively, to A, B, and C. Write

$$\alpha = \text{m}\sphericalangle BAC,\ \beta = \text{m}\sphericalangle ABC, \text{ and } \delta = \text{m}\sphericalangle ACB.$$

Then

$$\text{area}(ABA'C) = 2\alpha,\ \text{area}(BCB'A) = 2\beta, \text{ and area}(CAC'B) = 2\delta.$$

Notice that $S = \text{area}(\triangle ABC)$ is the area of the intersection of all three lunes. Therefore, the areas of the lunes without $\triangle ABC$ are $2\alpha - S$, $2\beta - S$, and $2\delta - S$. Observe that there are four pairs of congruent triangles on the sphere:

$$\begin{aligned}\triangle ABC &\cong \triangle A'B'C',\\ \triangle AB'C' &\cong \triangle A'BC,\\ \triangle BA'C' &\cong \triangle B'AC,\\ \triangle CA'B' &\cong \triangle C'AB.\end{aligned}$$

Moreover, these triangles cover the sphere, so their total sum must equal 4π. Hence,

$$2S + 4(\alpha + \beta + \delta) - 6S = 4\pi,$$

and then

$$S = (\alpha + \beta + \delta) - \pi.$$

The generalization to an arbitrary sphere is left to Exercise 6. ■

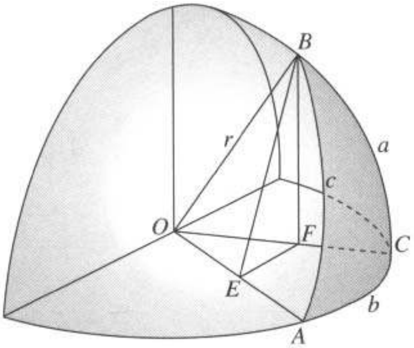
Identities

We shall use the convention that in $\triangle ABC$, the lowercase letters a, b, and c represent the lengths of the sides opposite the angles A, B, and C, respectively, and both McCleary (1994, 3–9) and Granville (1909, 193f) were used as sources. We begin with some fundamental identities.

THEOREM 12.3.2

If $\triangle ABC$ is on a sphere of radius r and $\sphericalangle C$ is the only right angle, then

- $\sin a/r = \sin c/r \sin A$.
- $\sin b/r = \sin c/r \sin B$.
- $\cos A = \cos a/r \sin B$.
- $\cos B = \cos b/r \sin A$.
- $\cos c/r = \cos a/r \cos b/r$.



PROOF

We will prove the first and the last, leaving the others to Exercise 2. Let O be the center of the sphere and from B drop a perpendicular to $\overline{OC}$ at F and then find E on $\overline{OA}$ so that $\overline{EF}$ is perpendicular to $\overline{OA}$. First notice that

$$m\sphericalangle BOF = \frac{a}{r}, \sphericalangle EOF = \frac{b}{r}, \text{and } m\sphericalangle BOE = \frac{c}{r}.$$

Then

$$\sin\frac{a}{r} = \frac{BF}{OB}, \sin\frac{c}{r} = \frac{BE}{OB}, \text{ and } \sin A = \sin\sphericalangle BEF = \frac{BF}{BE}.$$

Hence, $\sin a/r = \sin c/r \sin A$. We also have

$$\cos\frac{c}{r} = \frac{OE}{OB}, \cos\frac{a}{r} = \frac{OF}{OB}, \text{ and } \cos\frac{b}{r} = \frac{OE}{OF}.$$

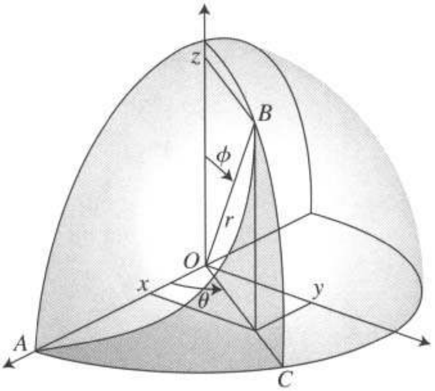
Thus, $\cos c/r = \cos a/r \cos b/r$. ■

The remaining theorems that we will prove concerning spherical triangles all have corresponding plane versions. We begin with the spherical analog to the Pythagorean Theorem.

■ **THEOREM 12.3.3 [Spherical Pythagorean Theorem]**

If $\sphericalangle C$ is the only right angle in $\triangle ABC$ on a sphere of radius r, then

$$\cos\frac{c}{r} = \cos\frac{a}{r}\cos\frac{b}{r}.$$



PROOF

We may assume by rotating the sphere, if necessary, that the coordinates of A are $(r,\ 0,\ 0)$ and C lies in the xy-plane. Recall that any point B on the sphere can be identified by the point $(r,\ \phi,\ \theta)$ in spherical coordinates. The point B can then be converted to Cartesian coordinates using the equations

$$x = r\sin\phi\cos\theta,\ y = r\sin\phi\sin\theta,\ \text{and}\ z = r\cos\phi,$$

where $\phi = \pi/2 - a/r$ and $\theta = b/r$. Therefore,

$$\begin{aligned} B &= \left(r\sin\left[\frac{\pi}{2}-\frac{a}{r}\right]\cos\frac{b}{r},\ r\sin\left[\frac{\pi}{2}-\frac{a}{r}\right]\sin\frac{b}{r},\ r\cos\left[\frac{\pi}{2}-\frac{a}{r}\right]\right) \\ &= \left(r\cos\frac{a}{r}\cos\frac{b}{r},\ r\cos\frac{a}{r}\sin\frac{b}{r},\ r\sin\frac{a}{r}\right) \end{aligned}$$

and

$$C = \left(r\cos\frac{b}{r},\ r\sin\frac{b}{r},\ 0\right).$$

Now apply some linear algebra and view $A(r,\ 0,\ 0)$ and $B(x,\ y,\ z)$ as vectors originating from the origin. Since the angle between these two vectors is $\sphericalangle AOB$ and the measures of this angle is c/r, we can apply the dot product to write

$$A \bullet B = \|A\|\,\|B\|\cos\frac{c}{r}.$$

Thus,

$$\cos\frac{c}{r} = \frac{A \bullet B}{\|A\|\,\|B\|} = \frac{r^2\cos a/r\cos b/r}{r^2} = \cos\frac{a}{r}\cos\frac{b}{r}. \blacksquare$$

The previous theorem is called the Spherical Pythagorean Theorem for two reasons. First, it gives a relationship between the sides of a spherical right triangle. Secondly, and more important, it is the Pythagorean Theorem when examined correctly. Using the Maclaurin series,

$$\cos x = \sum_{n=0}^{\infty} (-1)^n \frac{x^{2n}}{(2n)!},$$

we see that the Spherical Pythagorean Theorem becomes

$$\sum_{n=0}^{\infty} (-1)^n \frac{(c/r)^{2n}}{(2n)!} = \left(\sum_{n=0}^{\infty} (-1)^n \frac{(a/r)^{2n}}{(2n)!}\right) \cdot \left(\sum_{n=0}^{\infty} (-1)^n \frac{(b/r)^{2n}}{(2n)!}\right).$$

By multiplying the series on the right, subtracting one from both sides, and multiplying through by $-2r^2$, we find that there exists infinite series $S(r)$ and $T(r)$ such that

$$c^2 + S(r) = a^2 + b^2 + T(r), \tag{12.6}$$

where both $S(r) \to 0$ and $T(r) \to 0$ as $r \to \infty$. We conclude that as the radius of the sphere increases without bound, the equation of the Spherical Pythagorean Theorem approaches that of the standard Pythagorean Theorem. In other words, as the volume of the sphere increases, the geometry on its surface becomes more Euclidean.

The Law of Sines for plane trigonometry states that

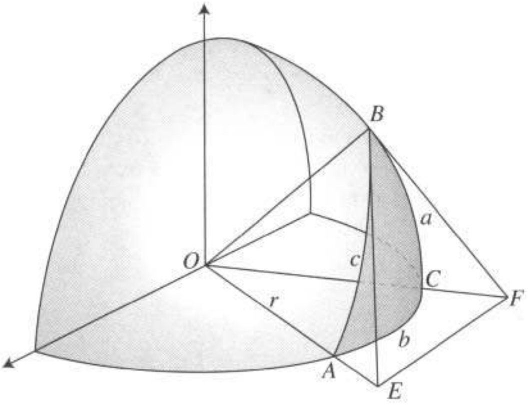
$$\frac{a}{\sin A} = \frac{b}{\sin B} = \frac{c}{\sin C}.$$

The following is the analogous theorem for the sphere.

■ THEOREM 12.3.4 [Spherical Law of Sines]

In $\triangle ABC$ on a sphere of radius r,

$$\frac{\sin(a/r)}{\sin A} = \frac{\sin(b/r)}{\sin B} = \frac{\sin(c/r)}{\sin C}.$$



PROOF

We will prove the theorem for right triangles first and then generalize. Let $\sphericalangle C$ in $\triangle ABC$ be right on the surface of a sphere with center O and radius r. Let plane EBF be tangent to the sphere at B. Assume that $\overline{OA}$ is produced to E and $\overline{OC}$ produced to F. Since $\overline{EB}$ and $\overline{BF}$ are tangent to the sphere, $\sphericalangle OBE$ and $\sphericalangle OBF$ are right angles. Hence, appealing to Pythagoras we see that

$$OE^2 = BE^2 + OB^2$$

and

$$OF^2 = BF^2 + OB^2.$$

Observe that planes EBF and OBF are perpendicular, so $\sphericalangle OFE$ is right. We then conclude that

$$OE^2 = EF^2 + OF^2.$$

Therefore,

$$EF^2 = OE^2 - OF^2 = (BE^2 + OB^2) - (BF^2 + OB^2),$$

and then

$$BE^2 = EF^2 + BF^2.$$

Therefore, $\sphericalangle EFB$ is right, and we then have

$$\sin \sphericalangle AOC = \frac{EF}{OE} = \frac{EF}{BE} \cdot \frac{BE}{OE} = \sin B \sin \sphericalangle AOB.$$

Since $b/r = \mathrm{m}\sphericalangle AOC$,

$$\frac{\sin(b/r)}{\sin B} = \sin \sphericalangle AOB.$$

Similarly, we could redraw the plane parallel at A instead of at B and find that

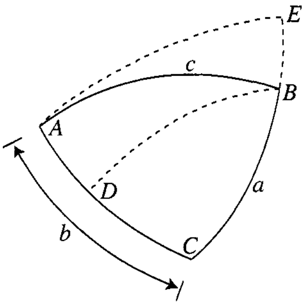
$$\frac{\sin(a/r)}{\sin A} = \sin \sphericalangle AOB.$$

Because $\sin C = 1$ and $c/r = \mathrm{m}\sphericalangle AOB$, we have

$$\frac{\sin(a/r)}{\sin A} = \frac{\sin(b/r)}{\sin B} = \frac{\sin(c/r)}{\sin C}.$$

Now take $\triangle ABC$ to be an arbitrary spherical triangle. Drop $\overline{BD}$ perpendicular to $\overline{AC}$. By examining $\triangle ABD$ and $\triangle CBD$, the equation for right triangles yields

$$\sin \frac{a}{r} \sin C = \sin \frac{BD}{r} = \sin \frac{c}{r} \sin A. \tag{12.7}$$



Extend $\overline{CB}$ to E such that $\overline{AE}$ joined is perpendicular to $\overline{EC}$. When we examine $\triangle ACE$ and $\triangle ABE$, we find that

$$\sin\frac{b}{r}\sin C = \sin\frac{AE}{r} = \sin\frac{c}{r}\sin(\pi - B) = \sin\frac{c}{r}\sin B. \tag{12.8}$$

These equations complete the proof. ■

The last theorem of this section is the spherical version of the Law of Cosines. Recall that the plane version states that in any $\triangle ABC$,

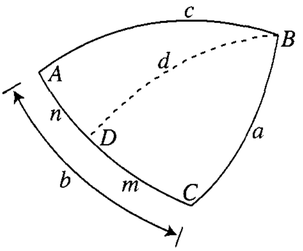
$$c^2 = a^2 + b^2 - 2ab\cos C.$$

When we examine the following result when r is small, we will find that it approximates the plane version (Exercise 11).

■ THEOREM 12.3.5 [Spherical Law of Cosines]

In $\triangle ABC$ on a sphere of radius r,

$$\cos\frac{a}{r} = \cos\frac{b}{r}\cos\frac{c}{r} + \sin\frac{b}{r}\sin\frac{c}{r}\cos A.$$



PROOF

Leaving the generalization to Exercise 10, we will prove the case when $r = 1$. Take spherical $\triangle ABC$ and drop an altitude from B to D on $\overline{AC}$. When we apply the Spherical Pythagorean Theorem (12.3.3) to $\triangle BCD$, letting $d = DB$, $m = DC$, and $n = AD$, we find that

$$\cos a = \cos d \cos m = \cos d \cos(b - n) = \cos d(\cos b \cos n + \sin b \sin n).$$

Therefore,

$$\cos a = \cos d \cos b \cos n + \cos d \sin b \sin n. \tag{12.9}$$

When we apply Theorem 12.3.3 to $\triangle BAD$, we get $\cos c = \cos d \cos n$, and substituting this into Equation 12.9 we see that

$$\cos a = \cos b \cos c + \cos d \sin b \sin n. \tag{12.10}$$

Furthermore, by Theorem 12.3.2 we have

$$\cos d = \frac{\cos c}{\cos n}.$$

Multiplying both sides of this equation by $\sin n$ we obtain

$$\cos d \sin n = \cos c \tan n. \tag{12.11}$$

However,

$$\cos A = \tan n \cot c \tag{12.12}$$

by Exercise 9, so $\tan n = \tan c \cos A$. We now substitute this into Equation 12.11 to find

$$\cos d \sin n = \cos c \tan c \cos A = \sin c \cos A,$$

and we may complete the proof by substituting into Equation 12.10. ■

Exercises

1. What would a triangle on the sphere look like if it had two right angles? Is it possible for a spherical triangle to have three right angles? Explain.

2. Let $\triangle ABC$ be on sphere of radius r with $\sphericalangle C$ the only right angle. Show the following identities.
   (a) $\sin b/r = \sin c/r \sin B$.
   (b) $\cos A = \cos a/r \sin B$.
   (c) $\cos B = \cos b/r \sin A$.

3. Let $\triangle ABC$ be on the unit sphere with $\sphericalangle C$ as the only right. Prove:
   (a) $\cos A = \tan b \cot c$.
   (b) $\sin b = \tan a \cot A$.
   (c) $\cos c = \cot A \cot B$
   (d) $\sec a = \sec A \sin B$

4. Find the remaining sides and angles (in degrees) of the spherical triangles given the following. Assume that C is the only right angle of the triangle.
   (a) $c = 110°, A = 80°$.
   (b) $c = 100°, b = 115°$.
   (c) $c = 120°, a = 20°$.
   (d) $B = 150°, b = 160°$.
   (e) $B = 150°, a = 110°$.

5. Prove that the following geometric results hold for $\triangle ABC$ on the unit sphere.
   (a) $a < b + c$.
   (b) If $a \neq b$, then $A \neq B$.
   (c) $a < b$ if and only if $A < B$.
   (d) $a + b + c < 2\pi$.
   (e) $\pi < A + B + C < 3\pi$.

6. Given (r, ϕ, θ) in spherical coordinates, show that the corresponding point in Cartesian coordinates is given by

$$\begin{aligned} x &= r \sin\phi \cos\theta, \\ y &= r \sin\phi \sin\theta, \\ z &= r \cos\phi. \end{aligned}$$

7. Prove Equation 12.12 in the proof of Theorem 12.3.5.

8. Generalize the proof of Theorem 12.3.5 to a sphere with any radius.

9. Use the Maclaurin series for sine and cosine to show that the Spherical Law of Cosines (12.3.5) yields an equation that approximates the plane Law of Cosines for small spherical triangles.

10. Prove Girard's Theorem (12.3.1) for a sphere of any radius.

11. Confirm Equations 12.7 and 12.8 from the proof of Theorem 12.3.4.

12. Verify for $\triangle ABC$ on the unit sphere:
    (a) $\cos A = \cos a \sin B \sin C - \cos B \cos C$.
    (b) $\cot A \sin C + \cos b \cos C = \cot a \sin b$.

12.4 HOROSPHERES

Both Bolyai and Lobachevski defined a three-dimensional analog to the horocycle. Bolyai did it by selecting a point A in space and an ideal point Ω (*Appendix* 11). He defined

$$\mathcal{F} = \{X : \sphericalangle AX\Omega \cong \sphericalangle XA\Omega\}.$$

The line $\overleftrightarrow{A\Omega}$ we will call the **axis** of $\mathcal{F}$. Like horocycles, at each point on $\mathcal{F}$ there is a line that is parallel to the axis. Each of these lines is parallel to each other (Exercise 6 in Section 12.1), so we can also view them as axes.

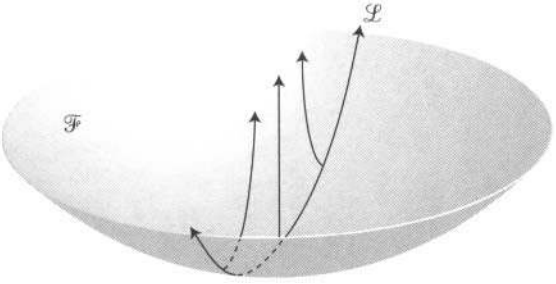


Figure 12.10 The horosphere $\mathcal{F}$ with generating horocycle $\mathcal{L}$.

If we let $B \in \mathcal{F}$, the plane Λ that contains A, B, and Ω intersects $\mathcal{F}$, resulting in a horocycle $\mathcal{L}$ as described in Equation 12.3. If we revolve Λ about $\overline{A\Omega}$, then we see that Bolyai's definition is equivalent to Lobachevski's.

■ **DEFINITION 12.4.1** [*Theory of Parallels* 34]

A **horosphere** (or **boundary surface**) is the surface $\mathcal{F}$ formed by revolving a horocycle about one of its axes.

Notice that due to the constant curvature of horocycles, if Λ instead makes an angle with $\overline{A\Omega}$, it will determine a circle on the surface of $\mathcal{F}$ (Exercise 3). Since a horocycle under **HR** is a line, the horosphere is a plane in Euclidean geometry. Under **HA** it looks more like Figure 12.10.

Induced Euclidean Geometry

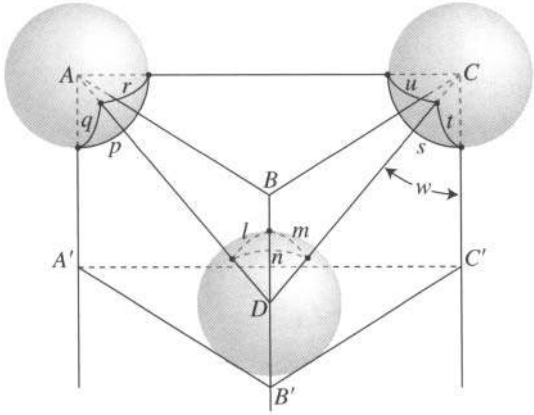
Despite assuming the Hypothesis of the Acute Angle, there is a natural interpretation of the term *line* that yields a Euclidean geometry on the surface of a horosphere. We first need to prove a theorem.

■ **THEOREM 12.4.2** [*Theory of Parallels* 28]

[HA] If three planes intersect each other in parallel lines, the sum of the angles that the planes make with each other equals two right angles.

PROOF

Suppose that three planes intersect in $\overline{AA'}$, $\overline{BB'}$, and $\overline{CC'}$ and that the three lines are parallel. These planes make angles with each other of measure x at $\overline{AA'}$, y at $\overline{BB'}$, and z at $\overline{CC'}$ (not identified in the diagram on page 426). Take D on $\overline{BB'}$ and pass through it a plane containing A and C. This fourth plane intersects $ABB'A'$ in $\overline{AD}$ and $CBB'C'$ in $\overline{CD}$. Denote the angle of inclination of plane ACD with $ACC'A'$ by w. We now construct three spheres, one each



centered at A, C, and D. This results in three spherical triangles:

- The vertices of the spherical triangle at A are the intersections of $\overline{AA'}$, $\overline{AD}$, and $\overline{AC}$ with the sphere. Let its area be α and its sides have length p, q, and r. Observe that the measure of the angle opposite q is w, the angle opposite r is x, and by Girard's Theorem (12.3.1) the angle opposite p has measure $\alpha - w - x + \pi$. This is summarized in the following table:

length	opposite angle
p	$\alpha - w - x + \pi$
q	w
r	x

- Similarly, the sphere at C intersects $\overline{AC}$, $\overline{CD}$, and $\overline{CC'}$, forming a spherical triangle of area β:

length	opposite angle
s	$\beta - w - z + \pi$
t	w
u	z

- Let δ be the area of the spherical triangle formed by the sphere at D. We note that the angle opposite l in the diagram is supplementary to the angle opposite s in the sphere at C. This is because they both have one side in the plane ACD and their other side in the plane $BCC'B'$, but these sides are on opposite sides of ACD. Similarly, the angle opposite m and the angle opposite p are also supplementary. Therefore, we describe the spherical triangle at D by a table:

length	opposite angle
l	$w + z - \beta$
m	$w + x - \alpha$
n	y

Therefore,

$$\delta = (x + y + z - \pi) + 2w - \beta - \alpha$$

by Girard's Theorem. Now let $w \to 0$. We see that both $q \to 0$ and $t \to 0$, so $\alpha \to 0$ and $\beta \to 0$. Also, the sides l and m approach zero, which means that $\delta \to 0$. But the angles x, y, and z remain fixed. Hence, $x + y + z = \pi$. ■

On a horosphere $\mathcal{F}$ let the word *point* refer to a regular point and let the word *line* refer to a horocycle. These choices impart a geometric system upon $\mathcal{F}$ called the **induced Euclidean geometry**. Let A, B, and C be points on $\mathcal{F}$ but not all on the same horocycle. Call the three horocycles determined by these points AB, BC, and AC. Take three planes that each contain an axis of $\mathcal{F}$ and also intersect the horosphere in AB, BC, and AC, respectively. Define the angle between any two of these horocycles to be the angle between their corresponding planes. (This is similar to how we defined the measure of angles on a sphere.) By Theorem 12.4.2, the sum of the internal angles of $\triangle ABC$ on $\mathcal{F}$ is equal to two right angles. This means that the Parallel Postulate holds true in the induced geometry by Corollary 11.2.12.

■ **THEOREM 12.4.3** [*Theory of Parallels* 34, *Appendix* 21]

The induced geometry on a horosphere is Euclidean.

The last result means that inside a geometry that satisfies **HA**, there is a surface that can naturally be interpreted as a Euclidean plane. The German mathematician David Hilbert showed that there is no such copy of **HA** in Euclidean geometry (Bonola 1912, 145).

Spherical Trigonometry and HA

As we study the sphere with infinite radius under **HA**, it is natural to ask about the status of a sphere with finite radius under the same hypothesis. The answer will involve two technical results, the second requires two horospheres.

Let $\triangle ABC$ be such that $m\sphericalangle A = \Pi(\alpha)$, $m\sphericalangle B = \Pi(\beta)$, and $\sphericalangle C$ is a right angle (Figure 12.11). Find A' in space so that $\overline{AA'}$ is perpendicular to the plane ABC. In addition, find B' and C' so that $\overline{BB'}$ and $\overline{CC'}$ are parallel to $\overline{AA'}$. These lines are also mutually parallel and are the intersections of three planes that make angles with each other with the following measures:

$$\Pi(\alpha) \text{ at } \overline{AA'},\ \Pi(\alpha') \text{ at } \overline{BB'}, \text{ and } \pi/2 \text{ at } \overline{CC'},$$

where α' is chosen so that

$$\Pi(\alpha) + \Pi(\alpha') = \pi/2$$

by Theorem 12.4.2. At B construct a unit sphere. Let B_1, B_2, and B_3 be the intersections of the sphere with $\overline{BC}$, $\overline{BA}$, and $\overline{BB'}$, respectively. Then the measurements of spherical $\triangle B_1B_2B_3$ are

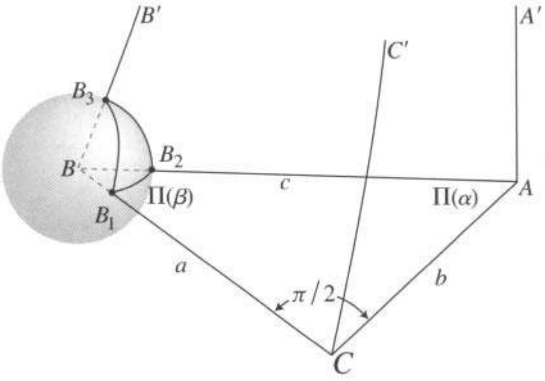


Figure 12.11 Deriving a spherical triangle from a plane triangle.

vertex	measure	opposite side
B_1	$\Pi(b)$	$\Pi(c)$
B_2	$\pi/2$	$\Pi(a)$
B_3	$\Pi(\alpha')$	$\Pi(\beta)$

We will return to this shortly, but first we prove the following.

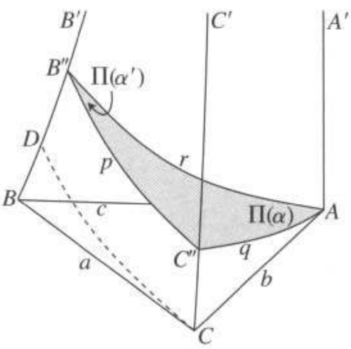
THEOREM 12.4.4 [*Theory of Parallels* 35]

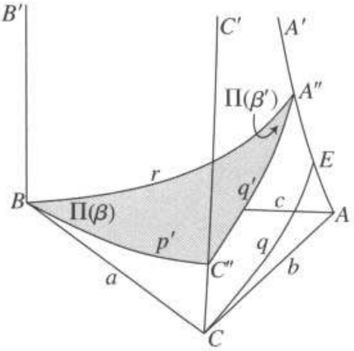
[HA] If m$\sphericalangle A = \Pi(\alpha)$, m$\sphericalangle B = \Pi(\beta)$, and $\sphericalangle C$ is right in $\triangle ABC$, then:

- $\sin \Pi(c) = \sin \Pi(a) \sin \Pi(b)$.
- $\sin \Pi(\beta) = \cos \Pi(\alpha) \sin \Pi(a)$.
- $\sin \Pi(\alpha) = \cos \Pi(\beta) \sin \Pi(b)$.
- $\cos \Pi(b) = \cos \Pi(c) \cos \Pi(\alpha)$.
- $\cos \Pi(a) = \cos \Pi(c) \cos \Pi(\beta)$.

PROOF

Let $\triangle ABC$ be as described in the hypothesis of the theorem. Let $\overline{AA'}$ be perpendicular to ABC at A and let $\overline{BB'}$ and $\overline{CC'}$ be parallel to $\overline{AA'}$. With axis $\overline{AA'}$ describe a horosphere that contains A and intersects $\overline{BB'}$ at B'' and $\overline{CC'}$ at C''. These three points are joined by horocycles. Each is the intersection of the horosphere with a plane that contains an axis of the horosphere. Since the angle between two of these horocycles is defined to be the angle between the two planes and letting $p = B''C''$, $q = AC''$, and $r = AB''$, we see that $\triangle AB''C''$ on the surface of the horosphere can be described by





vertex	measure	opposite side
A	$\Pi(\alpha)$	p
B''	$\Pi(\alpha')$	q
C''	$\pi/2$	r

We may apply plane trigonometry because the induced geometry on the horosphere is Euclidean (Theorem 12.4.3) and write

$$q = r \cos \Pi(\alpha). \tag{12.13}$$

Now reverse the setup by erecting the perpendicular at B, but still let $\overline{AA'}$, $\overline{BB'}$, and $\overline{CC'}$ be parallel. Place a horosphere with axis $\overline{BB'}$ at B and let it intersect $\overline{AA'}$ at A'' and $\overline{CC'}$ at C''. Let $q' = C''A''$ and $p' = BC''$. Since all horocycles have the same curvature, $BA'' = r$. Place a horocycle at C so that it is concentric with $C''A''$. Its length is q. Since all horocycles are congruent, there exists a function f that measures the distance from the plane ABC to a horocycle along an axis. That is, $f(b) = AE$, $f(a) = CC'' = EA''$, and we may conclude that

$$f(c) = AA'' = AE + EA'' = f(a) + f(b). \tag{12.14}$$

Then by Theorem 12.2.9, $q = q'e^{kf(a)}$ for some $k > 0$, and again since the induced geometry on a horosphere is Euclidean, we have $q' = r \sin \Pi(\beta)$, so that

$$q = re^{kf(a)} \sin \Pi(\beta). \tag{12.15}$$

Therefore, setting Equation 12.13 equal to Equation 12.15 gives

$$\cos \Pi(\alpha) = e^{kf(a)} \sin \Pi(\beta). \tag{12.16}$$

A similar construction of $\triangle ABC$ with the two nonright angles having measures $\Pi(b')$ and $\Pi(c)$ will yield

$$\sin \Pi(b) = e^{kf(a)} \sin \Pi(c). \tag{12.17}$$

because $\cos \Pi(b') = \sin \Pi(b)$ (Exercise 5). Therefore, by multiplying both sides of Equation 12.17 by $e^{kf(b)}$, we have

$$e^{kf(b)} \sin \Pi(b) = e^{kf(c)} \sin \Pi(c)$$

by Equation 12.14. An argument similar to the above will yield

$$e^{kf(a)} \sin \Pi(a) = e^{kf(b)} \sin \Pi(b).$$

Finally, we note that the lengths of a and b may be chosen independently of each other. Hence, since $f(0) = 0$ and $\Pi(0) = \pi/2$, let $b = 0$ and conclude that

$$\sin \Pi(a) = e^{-kf(a)}.$$

Therefore, by Equation 12.17,

$$\sin \Pi(c) = \sin \Pi(a) \sin \Pi(b),$$

and then by Equation 12.16,

$$\sin \Pi(\beta) = \cos \Pi(\alpha) \sin \Pi(a).$$

The remaining three identities follow by a "mutation of the letters." ■

We close the section with the remarkable result that the geometry on the surface of a sphere where *line* is interpreted as *great circle* is independent of the hypothesis chosen. We accomplish this by examining the sphere described in Figure 12.11 and the corresponding table at the top of page 36.

■ **COROLLARY 12.4.5 [*Theory of Parallels* 35, *Appendix* 26]**

The geometry on the surface of a sphere is the same whether **HR** or **HA** is assumed.

PROOF

If we assign $a = \Pi(c)$, $b = \Pi(\beta)$, $c = \Pi(a)$, $A = \Pi(b)$, and $B = \Pi(\alpha')$ for the dimension of a triangle on a unit sphere, the identities of Theorem 12.4.4 are seen to be identical to the identities of Theorem 12.3.2. ■

Exercises

1. Let A, B, and C be points on a horosphere $\mathcal{F}$ but not all on the same horocycle. The three horocycles through these points form a triangle on $\mathcal{F}$. Show that if $\sphericalangle C$ is right, then $AB^2 = AC^2 + BC^2$.

2. Let $\mathcal{L}$ be a horocycle on the surface of a horosphere $\mathcal{F}$ with axis $\overline{A\Omega}$. Let B be on $\mathcal{F}$ but not on $\mathcal{L}$. Prove:
   (a) B corresponds with A.
   (b) B corresponds with every other point on $\mathcal{F}$.

3. Take A, B, and C to be points on the surface of a horosphere but not all on the same horocycle. Show that A, B, and C lie on a circle on the horosphere. (*Hint:* Find the intersection of the lines that are the perpendicular bisectors of the sides of the triangle.)

4. Redo Exercise 3 using another method.

5. Let $\triangle ABC$ be as in the proof of Theorem 12.4.4 but such that $\text{m}\sphericalangle A = \Pi(b')$, $\text{m}\sphericalangle B = \Pi(c)$, $\text{m}\sphericalangle C = \pi/2$, $BC = a$, $AC = \alpha$, and $AB = \beta$.
   (a) Show $\cos \Pi(b') = \sin \Pi(b)$.
   (b) Use $\triangle ABC$ to demonstrate Equation 12.17.

6. Suppose that spherical $\triangle B_1B_2B_3$ in Figure 12.11 was, instead, constructed at A. Provided that $\overline{AA'}$ is still perpendicular to plane ABC, find the measures of the angles and sides of $\triangle B_1B_2B_3$, where B_3 is the intersection of $\overline{AA'}$ with the sphere.

7. Let f be the function defined in the proof of Theorem 12.4.4. In the first diagram of that theorem, draw a horocycle through C that is concentric to the horocycle $B''C''$ and intersects $\overline{BB''}$ at D. Using B, B'', and D, show that $f(c) = f(a) + f(b)$.

8. Give the details for the "mutation of letters" from the proof of Theorem 12.4.4:
   (a) $\sin \Pi(\alpha) = \cos \Pi(\beta) \sin \Pi(b)$.
   (b) $\cos \Pi(b) = \cos \Pi(c) \cos \Pi(\alpha)$.
   (c) $\cos \Pi(a) = \cos \Pi(c) \cos \Pi(\beta)$.

9. Provide the details for the steps labeled as "similar" in the proof of Theorem 12.4.4.

12.5 EVALUATING THE PI FUNCTION

We have seen that Lobachevski's Π function has some very nice properties. In this section we derive a formula for it. The proof given is by Lobachevski with some modification by Manning (1901, 45–46, 58).

■ **LEMMA 12.5.1**

If n is a positive integer and

$$f(x) = \frac{f(2x)}{f(x)} = \frac{f(3x)}{f(2x)} = \cdots = \frac{f(nx)}{f([n-1]x)},$$

then $f(nx) = [f(x)]^n$.

PROOF

By hypothesis we conclude that

$$f(nx) = \frac{[f([n-1]x)]^2}{f([n-2]x)},\ f([n-1]x) = \frac{[f([n-2]x)]^2}{f([n-3]x)},\ \ldots,$$

$$f(3x) = \frac{[f(2x)]^2}{f(x)},\ f(2x) = [f(x)]^2.$$

Hence,

$$f(nx) = \frac{[f([n-1]x)]^2}{f([n-2]x)} = f([n-1]x)\frac{f([n-1]x)}{f([n-2]x)} = f([n-1]x)f(x),$$

with the last equality holding by the hypothesis. By a similar argument,

$$f([n-1]x) = f([n-2]x)f(x),$$

so

$$f(nx) = f([n-2]x)[f(x)]^2.$$

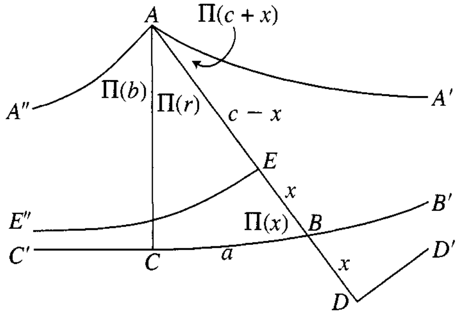
Continuing, we find that $f(nx) = [f(x)]^n$. ■

The next theorem contains the exact relationship between the length of a segment and its corresponding angle of parallelism. Lobachevski's formula did not include the constant k. Instead, he modified the units along the x-axis so that the constant could be taken to equal 1. Bolyai did not do this, so the constant remained an important part of his equation. His father was very much troubled that his son could never find a way to remove the constant. Farkas believed that the final description of the new geometry should be able to determine the value of k. János was content to leave it undetermined (Bonola 1912, 99).

■ **THEOREM 12.5.2** [*Theory of Parallels* **36**, *Appendix 29*]

[HA] There exists $k > 0$ such that for all $x \geqslant 0$,

$$\tan\frac{1}{2}\Pi(x) = e^{-kx}.$$



PROOF

We first note that if $x = 0$,

$$\tan\frac{1}{2}\Pi(0) = \tan\pi/4 = 1$$

because $\Pi(0) = \pi/2$, so the equation holds. So, let $x > 0$ and form $\triangle ABC$ with $m\sphericalangle ABC = \Pi(x)$ and $\sphericalangle ACB$ right. Further, since Π is onto (Theorem 12.1.6), there exists $r > 0$ such that $m\sphericalangle BAC = \Pi(r)$. To ease our calculations later, let $a = BC$, $b = AC$, and $c = AB$. Notice that the diagram assumes that $c > x$. Next extend $\overline{AB}$ to point D, where $BD = x$. Find D' so that $\overline{DD'}$ is perpendicular to $\overline{AD}$. Producing $\overline{CB}$ to B', we see that $\overline{BB'}$ is parallel to $\overline{DD'}$ because $m\sphericalangle B'BD = \Pi(x)$. Finally, draw $\overline{AA'}$ so it is parallel to $\overline{DD'}$. This gives us $m\sphericalangle A'AD = \Pi(c+x)$. Thus, by Theorem 12.1.1 and Theorem 12.1.3, $\overline{AA'}$ is also parallel to $\overline{CB'}$ and $m\sphericalangle A'AC = \Pi(b)$. Hence,

$$\Pi(b) = \Pi(r) + \Pi(c+x). \tag{12.18}$$

There are now two cases to consider. Either $c > x$ or it is not. Suppose that $c > x$ and find E on $\overline{AB}$ such that $AE = c - x$ and $EB = x$. At E construct $\overline{EE'}$ so that it meets $\overline{AB}$ in right angles and produce $\overline{BC}$ to C'. We see that $\overline{BC'}$ and $\overline{EE'}$ are parallel since $m\sphericalangle ABC = \Pi(x)$. Draw $\overline{AA''}$ parallel to $\overline{CC'}$. This means that we have $m\sphericalangle CAA' = \Pi(b)$. Therefore, $\overline{AA'}$ is parallel to $\overline{EE'}$ by Theorem 12.1.3. Thus, $m\sphericalangle EAA' = \Pi(c-x)$, and we conclude that

$$\Pi(b) = \Pi(c-x) - \Pi(r). \tag{12.19}$$

That this equation holds when $c \leqslant x$ is left to Exercise 2.

We may now combine Equations 12.18 and 12.19 to find that

$$\begin{aligned} 2\Pi(b) &= \Pi(c-x) + \Pi(c+x), \\ 2\Pi(r) &= \Pi(c-x) - \Pi(c+x). \end{aligned}$$

Therefore,

$$\frac{\cos\Pi(b)}{\cos\Pi(r)} = \frac{\cos\frac{1}{2}[\Pi(c-x)+\Pi(c+x)]}{\cos\frac{1}{2}[\Pi(c-x)-\Pi(c+x)]}.$$

By Theorem 12.4.4,

$$\cos\Pi(c) = \frac{\cos\Pi(b)}{\cos\Pi(r)},$$

and if we let $\theta = \frac{1}{2}\Pi(c-x)$ and $\phi = \frac{1}{2}\Pi(c+x)$, we find

$$\cos\Pi(c) = \frac{\cos(\theta+\phi)}{\cos(\theta-\phi)},$$

from which some trigonometric identities give

$$2\cos^2\tfrac{1}{2}\Pi(c) = \frac{\cos(\theta+\phi)+\cos(\theta-\phi)}{\cos(\theta-\phi)},$$

and then

$$\sec^2\tfrac{1}{2}\Pi(c) - 1 = \frac{\sin\theta\sin\phi}{\cos\theta\cos\phi}.$$

Therefore,

$$\tan^2\tfrac{1}{2}\Pi(c) = \tan\tfrac{1}{2}\Pi(c-x)\tan\tfrac{1}{2}\Pi(c+x).$$

For all positive integers n, let $y = c - nx$ so that

$$\tan^2 \tfrac{1}{2}\Pi(y + nx) = \tan \tfrac{1}{2}\Pi(y + (n-1)x) \tan \tfrac{1}{2}\Pi(y + (n+1)x),$$

and then

$$\frac{\tan \frac{1}{2}\Pi(y+x)}{\tan \frac{1}{2}\Pi(y)} = \frac{\tan \frac{1}{2}\Pi(y+2x)}{\tan \frac{1}{2}\Pi(y+x)} = \cdots = \frac{\tan \frac{1}{2}\Pi(y+nx)}{\tan \frac{1}{2}\Pi(y+(n-1)x)}.$$

Because $\tan \frac{1}{2}\Pi(0) = 1$, letting $y = 0$ yields

$$\tan \tfrac{1}{2}\Pi(x) = \frac{\tan \frac{1}{2}\Pi(2x)}{\tan \frac{1}{2}\Pi(x)} = \cdots = \frac{\tan \frac{1}{2}\Pi(nx)}{\tan \frac{1}{2}\Pi([n-1]x)}.$$

Hence, by Lemma 12.5.1,

$$\tan \tfrac{1}{2}\Pi(nx) = \tan^n \tfrac{1}{2}\Pi(x)$$

for all positive integers n. Since $\Pi(x) < \pi/2$, we have $\tan \frac{1}{2}\Pi(x) < 1$. Therefore, by Lemma 12.2.8 there exists $k > 0$ such that

$$\tan \tfrac{1}{2}\Pi(x) = e^{-kx}. \blacksquare$$

Since Π is undefined for negative numbers, Lobachevski extended the domain of Π to all real numbers by defining

$$\Pi(x) + \Pi(-x) = \pi. \tag{12.20}$$

With this definition we can show that $\tan \frac{1}{2}\Pi(x) = e^{-kx}$ for all real numbers x (Exercise 3).

The Graph of Pi

The Theorem 12.5.2 allows us to compute values for Π, for it follows quickly that

$$\Pi(x) = 2\tan^{-1} e^{-kx}.$$

The graph of this function is given in Figure 12.12 for $k = 1$. Notice that this confirms the basic properties of Π listed in Section 12.1.

We should now observe that there is a relationship between Π and the **hyperbolic functions**. For any real number x, define **hyperbolic cosine** and **hyperbolic sine** as

$$\cosh x = \frac{e^x + e^{-x}}{2},$$

$$\sinh x = \frac{e^x - e^{-x}}{2}.$$

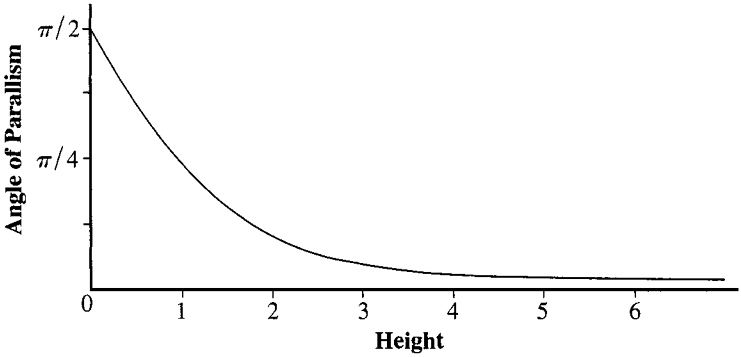


Figure 12.12 The graph of $\Pi(x) = 2\tan^{-1} e^{-x}$.

The hyperbolic versions of tangent, cotangent, secant, and cosecant are defined as their trigonometric counterparts. In addition, there are hyperbolic identities such as

$$1 - \tanh^2 x = \operatorname{sech}^2 x. \tag{12.21}$$

The hyperbolic functions can be used to help evaluate expressions that involve the composition of standard trigonometric functions and Π. For example, to evaluate $\cos \Pi(x)$, first note that

$$e^{-2kx} = \tan^2 \tfrac{1}{2}\Pi(x) = \frac{1 - \cos \Pi(x)}{1 + \cos \Pi(x)}.$$

Therefore,

$$\cos \Pi(x) + e^{-2kx} \cos \Pi(x) = 1 - e^{-2kx},$$

and then

$$\cos \Pi(x) = \frac{1 - e^{-2kx}}{1 + e^{-2kx}} = \frac{e^{kx} - e^{-kx}}{e^{kx} + e^{-kx}} = \frac{\sinh kx}{\cosh kx},$$

and we may conclude that

$$\cos \Pi(x) = \tanh kx. \tag{12.22}$$

We use this last equation to evaluate $\sin \Pi(x)$. From

$$\cos^2 \Pi(x) + \sin^2 \Pi(x) = 1$$

we may substitute and use Equation 12.21 to find

$$\sin^2 \Pi(x) = 1 - \cos^2 \Pi(x) = 1 - \tanh^2 kx = \operatorname{sech}^2 kx.$$

Therefore,

$$\sin \Pi(x) = \operatorname{sech} kx. \tag{12.23}$$

Pi in Space

Beginning in 1818 there was a large effort to map the entire Kingdom of Hanover. The interest in geodesy at the time was partly a theoretical one to use the methods of calculus to determine the shape of the globe and partly a practical one to create accurate maps to the benefit of commerce and the military. It was Gauss who was asked to lead the initial effort. He had previously made some geodetic studies after his return to Brunswick, so he was interested when he was offered the leadership position. Over a period of three summers, Gauss spent most of his time traveling. He led a small team of military men who took the measurements with a device called a heliotrope, which Gauss had invented (Bühler 1981, 95–98).

The work allowed Gauss an opportunity to conduct an experiment that would hopefully determine whether it was Euclidean or non-Euclidean geometry that was true. He decided that a check of the angle sum of a large triangle would provide a perfect test, so Gauss chose a triangle near Göttingen. Its vertices were mountain tops that had been surveyed previously, and its sides were approximately 40 miles long. Measured in degrees, the calculations yielded an angle sum for the triangle that was less than 2 seconds short of two right angles. This was well within the margin of error of the instruments that Gauss used, so he concluded that as far as measurement was concerned, it was safe to assume that the geometry near earth was Euclidean. However, since the defect did not calculate to zero, there was still some question (Burton 1985, 552).

Although not influenced directly by Gauss, Lobachevski shared his belief that empirical methods should determine the truth of the Parallel Postulate. Like Gauss, he rejected the prevalent Kantian philosophy of his day and believed that whether Euclid's geometry was true or not must be determined by experiment. Our senses must be allowed to inform our beliefs regarding mathematics. Our intuition and any notions that we may have pre-wired in our brains must not be trusted. To find his evidence, Lobachevski decided that he would need to examine large triangles. He did not use mountains; instead, Lobachevski found his large triangles in space (Rosenfeld 1988, 208).

Take the vertices of the triangle to be the points A, B, and C in Figure 12.13. Locate them at the centers of the earth, the sun, and a distant star, respectively. Assume that $\overline{AB}$ is perpendicular to $\overline{BC}$. With this setup Lobachevski used the

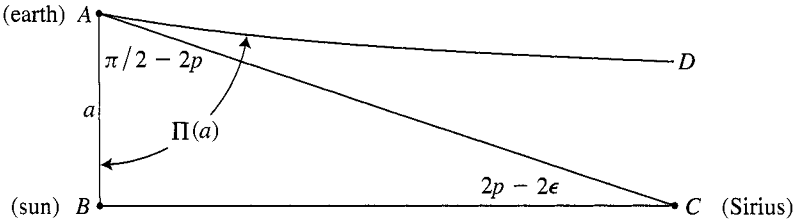

Figure 12.13 Lobachevski testing the geometry of space.

parallax angle, which is $\sphericalangle BCA$ in Figure 12.13, to measure how close to being Euclidean is space. Lobachevski chose Sirius for his calculations. Let $a = AB$,

$$\mathrm{m}\sphericalangle BAC = \frac{\pi}{2} - 2p, \text{ and } \mathrm{m}\sphericalangle BCA = 2p - 2\epsilon,$$

where $\epsilon \geqslant 0$ to allow for a possible positive defect in the triangle. Choose D so that $\sphericalangle BAD$ is the angle of parallelism. We conclude that

$$\Pi(a) > \frac{\pi}{2} - 2p,$$

and then

$$e^{-ka} = \tan\frac{1}{2}\Pi(a) > \tan\left(\frac{\pi}{4} - p\right) = \frac{1 - \tan p}{1 + \tan p}$$

for some constant k. Therefore, we conclude that

$$e^{ka} < \frac{1 + \tan p}{1 - \tan p}.$$

We know from calculus that if $|x| < 1$, then

$$\ln\frac{1+x}{1-x} = 2\left(x + \frac{x^3}{3} + \frac{x^5}{5} + \cdots + \frac{x^{2n+1}}{2n+1} + \cdots\right).$$

Since $0 < p < \pi/4$, we have $\tan p < 1$, and hence

$$ka < \ln\frac{1 + \tan p}{1 - \tan p} = 2\left(\tan p + \frac{\tan^3 p}{3} + \frac{\tan^5 p}{5} + \cdots + \frac{\tan^{2n+1} p}{2n+1} + \cdots\right).$$

Moreover,

$$2(\tan p + \tan^3 p + \tan^5 p + \cdots + \tan^{2n+1} p + \cdots) = \frac{2\tan p}{1 - \tan^2 p} = \tan 2p,$$

and we finally have that

$$ka < \tan 2p.$$

Lobachevski took the parallax of Sirius to be 1.24 arcseconds, but we know that it is closer to .375 arcseconds. Using the value of 93 million miles for the radius of earth's orbit, a little calculation yields

$$k < 1.95 \times 10^{-14}.$$

Therefore, Lobachevski drew the same conclusion as Gauss. Since $k = 0$ means that $\Pi(x) = \pi/2$ for all x, the very small k tells us that if the universe is not Euclidean, it is nearly so (Bonola 1912, 94–96).

The Imaginary

Lambert believed that his geometry would hold true on a sphere of imaginary radius (page 360). He did not explain how to visualize this, but if we take Lobachevski's equations and replace radius r with radius ir, we obtain familiar formulas from spherical geometry. To see how this works, we must make two notes. First, since the length of an arc of a circle with real radius r and central angle θ is $r\theta$,

> the length of an arc of a great circle on a sphere of imaginary radius is $ri\theta$.

Second, we need to extend the domain of Π to include any complex number. We already know that $\Pi(x) = 2\tan^{-1} e^{-kx}$. Without going into the details, to calculate $\Pi(a+bi)$, use the power series expansion for $2\tan^{-1} e^{-kx}$ and then substitute $a+bi$ in for x.

We now apply trigonometric functions to $\Pi(xi)$. We prove the first formula and leave the other two to Exercise 9. Using the power series for hyperbolic cosine, we have

$$\begin{aligned}\cosh xi &= 1 + \frac{(xi)^2}{2!} + \frac{(xi)^4}{4!} + \frac{(xi)^6}{6!} + \cdots \\ &= 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \cdots \\ &= \cos x.\end{aligned}$$

Therefore, by Equation 12.23,

$$\sin\Pi(xi) = \sec kx.$$

The other two substitutions are

$$\begin{aligned}\cos\Pi(xi) &= i\tan kx, \\ \tan\Pi(xi) &= -i\csc kx.\end{aligned}$$

Lobachevski used these equations to translate his trigonometric equations into those of spherical trigonometry. He showed (*Theory of Parallels* 37) that

$$\sin A\tan\Pi(a) = \sin B\tan\Pi(b), \tag{12.24}$$

$$\cos A\cos\Pi(b)\cos\Pi(c) + \frac{\sin\Pi(b)\sin\Pi(c)}{\sin\Pi(a)} = 1, \tag{12.25}$$

$$\cot A\sin C\sin\Pi(b) + \cos C = \frac{\cos\Pi(b)}{\cos\Pi(a)}, \tag{12.26}$$

$$\cos A + \cos B\cos C = \frac{\sin B\sin C}{\sin\Pi(a)}. \tag{12.27}$$

Then on a sphere of imaginary radius the second equation becomes

$$\cos A \cos \Pi(bi) \cos \Pi(ci) + \frac{\sin \Pi(bi) \sin \Pi(ci)}{\sin \Pi(ai)} = 1.$$

Using the substitutions above we obtain

$$\cos A(i \tan kb)(i \tan kc) + \frac{\sec kb \sec kc}{\sec ka} = 1,$$

which gives

$$-\cos A \cdot \frac{\sin kb \sin kc}{\cos kb \cos kc} + \frac{\cos ka}{\cos kb \cos kc} = 1.$$

Multiplying through by $\cos kb \cos kc$ yields

$$-\cos A \sin kb \sin kc + \cos ka = \cos kb \cos kc.$$

Thus,

$$\cos ka = \cos kb \cos kc + \sin kb \sin kc \cos A,$$

and this is Theorem 12.3.5. It is left to Exercise 10 to show that similar work with Lobachevski's trigonometric formulas gives

$$\sin A \sin kb = \sin B \sin ka$$

and

$$\cos A = \cos ka \sin B \sin C - \cos B \cos C.$$

These equations are the spherical trigonometry identities found in Theorem 12.3.4 and Exercise 12 of Section 12.3. This is what it means for this new geometry to be found on the surface of a sphere of imaginary radius.

Exercises

1. Confirm the following using the equation for $\Pi(x)$ given by Theorem 12.5.2.
    (a) Equation 12.1
    (b) Π is a strictly decreasing continuous function.

2. Prove Equation 12.19 for the cases $c = x$ and $c < x$.

3. Use Lobachevski's extension of Π in Equation 12.20 to show that for all real numbers x, $\tan \frac{1}{2}\Pi(x) = e^{-kx}$.

4. Draw the following, paying careful attention to all measurements.
    (a) The graph of Π when $k = .1, k = .5, k = 2, k = 10$.
    (b) A 60 – 90 omega triangle ($k = 1$).
    (c) $\triangle ABC$ where $m\sphericalangle C = 90°$, $m\sphericalangle B = 60°$, and $AC = 1$ ($k = 1$).

5. The area of $\triangle ABC$ is $k^2(\pi - A - B - C)$. Use this to explain why the maximum area of a triangle πk^2?

6. Find the area of $\triangle ABC$ where $m\sphericalangle C = 90°$, $m\sphericalangle B = 60°$, and $AC = 1$ $(k = 1)$.
7. Give a formula for the area of a quadrilateral $ABCD$ and find its maximum area.
8. Use the value of 93 million miles for the radius of earth's orbit about the sun.
   (a) Confirm that if the parallax of Sirius is .375 arcseconds, $k < 1.95 \times 10^{-14}$.
   (b) Find the maximum value of k using Lobachevski's value of 1.24 arcseconds for the parallax of Sirius.
   (c) Calculate $\Pi(1)$ using both of these k values.
   (d) Find the distance to Sirius assuming Euclidean geometry and assuming that $k = 1.95 \times 10^{-14}$. Is the difference significant?
9. Confirm that the following hold.
   (a) $\cos \Pi(xi) = i \tan kx$.
   (b) $\tan \Pi(xi) = i \csc kx$.
10. Show that for triangles on a sphere of imaginary radius,
   (a) $\sin A \sin kb = \sin B \sin ka$.
   (b) $\cos A = \cos ka \sin B \sin C - \cos B \cos C$.
11. The circumference of a circle with radius r is

$$C = \frac{2\pi}{k} \sinh kr,$$

and its area is

$$A = \frac{4\pi}{k^2} \sinh^2 2kr.$$

Confirm that these equations approach the Euclidean formulas as $k \to 0$.

12. For very small values of x,

$$\cos \Pi(x) \approx kx, \sin \Pi(x) \approx 1 - \frac{k^2x^2}{2}, \text{ and } \cot \Pi(x) \approx kx.$$

   (a) Confirm that this is the case.
   (b) Use these approximations to show that Lobachevski's trigonometric equations (12.24–12.27) are equivalent to

$$b \sin A = a \sin B,$$

$$a^2 = b^2 + c^2 - 2bc \cos A,$$

$$a \sin(A + C) = b \sin A,$$

$$\cos A + \cos(B + C) = 0.$$

   (c) Use these results to show that the angle sum of very small triangles is approximately equal to two right angles, showing that in the geometry of Lobachevski and Bolyai, very small regions of the plane are essentially Euclidean.

CHAPTER 13

BERNHARD RIEMANN

Riemann was born in Breselenz in Hanover on September 17, 1826. His full name was Georg Friedrich Bernhard Riemann, and he was the son of a Lutheran pastor. Following his father's wishes, he moved to Göttingen in 1846 to study theology and philosophy. After attending various mathematics courses, he realized that he had an aptitude for the subject, so after receiving permission from his father, Riemann switched fields. Unfortunately, he found himself unhappy at the university. Despite Gauss holding a chair in mathematics, Riemann was disappointed in the level of academic rigor of the courses. Because of this he moved to Berlin and studied mathematics with such notables as Dirichlet, Eisenstein, and Jacobi (Burton 1985, 563; Boyer and Merzbach 1991, 545).

In 1848, revolution embroiled Berlin, and Riemann found himself in the middle of something that was quite foreign to his nature. Riemann was a frail, unassuming person, but evidently motivated by a sense of duty to his country, he joined a group of students who were loyal to the crown. His activities for the group included a two-day stint in which he stood guard at the royal palace. This proved to be too much excitement for Riemann. He decided that it was time to leave, and in 1849 he returned to Göttingen to finish his doctoral degree. With Gauss as his dissertation advisor, he worked on a topic that was new and significant. It involved surfaces

Revolutions of Geometry. By Michael O'Leary
Copyright © 2010 John Wiley & Sons, Inc.

over the complex plane that we now call **Riemann surfaces**. The dissertation also included equations that were discovered independently by Augustin-Louis Cauchy. They are called the **Cauchy-Riemann equations**, and the proposition states that if f is a complex differentiable function of the form

$$f(x, y) = u(x, y) + iv(x, y),$$

then

$$\frac{\partial u}{\partial x} = \frac{\partial v}{\partial y} \text{ and } \frac{\partial v}{\partial x} = -\frac{\partial u}{\partial y}.$$

Gauss recognized in his student exceptional ability and was pleased with his results (Burton 1985, 563–564; Boyer and Merzbach 1991, 545).

Over the next few years Riemann continued his research. Besides his mathematical pursuits, he studied physics as an assistant to Wilhelm Weber. As a result of his work, Riemann published numerous papers. The topics included heat, light, gases, magnetism, gravitation, fluid dynamics, and acoustics. Riemann even conjectured that space was curved and that this was the reason that gravity works on objects at a distance (Kline 1972, 655–656; Gray 2007, 189).

Then in 1854 Riemann was ready to become a *privatdozent* at Göttingen. For his *Habilitationsschrift*, Riemann gave three topics to Gauss. The first involved using a trigonometric series to represent a function. The second dealt with quadratic equations. The last was titled *On the Hypotheses Which Lie at the Bases of Geometry*. Riemann was quoted as being surprised at Gauss going against the "usual convention" by picking his last suggestion, but Riemann should not have been surprised at the choice. The first two were too elementary for the presentation. Moreover, there is evidence that Riemann was both willing and ready for the topic (Laugwitz 1999, 219–220; Gray 2007, 189).

On June 10, 1854 Riemann gave his talk. Since mathematics was housed in the school of philosophy at Göttingen, the audience included both mathematicians and philosophers. For this reason his essay (Riemann 1854) and the accompanying presentation focused on big-picture issues and provided little detail. Despite the subject being geometry, Riemann included no diagrams and only two equations. Nonetheless, in this one presentation, Riemann gave a completely new definition of geometry. From the time of Euclid geometry had been the study of objects in space, and it is the choice of postulates that determines the behavior of these objects. Up until the time of Gauss, these postulates were viewed as self-evident truths. Gauss's work, along with that of Lobachevski and Bolyai, showed otherwise by proving that the Parallel Postulate may or may not describe space accurately. Its truth is now an empirical question, one Riemann, as Lobachevski before him (page 436), believed would be answered by astronomy (Burton 1985, 565).

The goal of Riemann's redefinition was to generalize the system of Euclid. He did not simply change the postulate set as did Lobachevski and Bolyai. In fact, it is doubtful that he knew their work. Instead, Riemann set his focus on the two different types of problems of the geometer. The first seeks to determine the intrinsic properties of a surface. An **intrinsic** property is one that requires no information about the encompassing space. Imagine little creatures living on a surface. They would not need to leave the surface to determine an intrinsic property. An example is the measure of angles. One of the creatures can easily take a little protractor and find the measure of any given angle without ever leaving home. The second type of geometric problem involves the examination of the various methods by which one surface can be mapped onto another. Sometimes these functions distort the surface by bending or warping it, but sometimes the maps simply superimpose one surface on top of the other. We do this, for example, when we study congruent figures. Congruence means that the figures look identical in size and shape so that one can be lined up on top of the other (Gray 2004, 85; Laugwitz 1999, 237).

Since geometry assumes that surfaces exist in three dimensions, Riemann needed a new geometric notion that could generalize the Euclidean concept of space. He accomplished this with what he called a **manifoldness** (Riemann 1854, I.1, 57). A manifoldness was a multidimensional space consisting of points. These points were identified by the use of coordinates, and the number of coordinates needed gave the number of dimensions of the space. Today we use the term *manifold* instead of *manifoldness*, and we define a **manifold** to be a topological space that has the property that every point is contained within a neighborhood that is essentially Euclidean. The primary example of a manifold is $\mathbb{R}^n$. Other examples include the surfaces of spheres, cylinders, and tori.

Riemann's manifoldness had the additional property that the length of any curve in the space was **rectifiable**; that is, its length could be measured. This was done using infinitesimally small rulers. Hence, instead of geometric postulates Riemann used the methods of calculus to study his manifolds. This field of mathematics that studies curves and surfaces using calculus is called **differential geometry** (Gray 2004, 85).

13.1 METRIC SPACES

Riemann taught that all that is needed for a geometry are its points and a function to compute distances. Since there are infinitely many such functions, there are infinitely many geometries. This implies the concept of a metric space (O'Leary 2002, 325–348; Marsden and Hoffman 1993; Simmons 1963). Although it came after Riemann's work, a metric space shares two main features with his manifoldness, namely, a set of points and a distance function.

■ DEFINITION 13.1.1

Let M be a nonempty set and $d : M \times M \to \mathbb{R}$ a function such that for all $x, y, z \in M$:

- $d[x, y] \geqslant 0$.
- $d[x, y] = 0$ if and only if $x = y$.
- $d[x, y] = d[y, x]$.
- $d[x, y] \leqslant d[x, z] + d[z, y]$.

The pair (M, d) is called a **metric space**. The function d is the distance function, and it is called a **metric**. The last condition is called the **Triangle Inequality**.

There are many examples of metric spaces. For example, $(\mathbb{R}, d)$ is a metric space where

$$d[x, y] = |x - y|.$$

The check of the first three conditions is left to Exercise 1. To see that the Triangle Inequality holds, notice that for all $a, b \in \mathbb{R}$,

$$-|a| \leqslant a \leqslant |a| \text{ and } -|b| \leqslant b \leqslant |b|.$$

Adding these inequalities yields

$$-(|a| + |b|) \leqslant a + b \leqslant |a| + |b|.$$

Therefore,

$$|a + b| \leqslant |a| + |b|. \tag{13.1}$$

Similarly, if we define the distance function d as

$$d[X, Y] = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2}$$

for all $X = (x_1, y_1)$ and $Y = (x_2, y_2)$, we see that $(\mathbb{R}^2, d)$ is a metric space (Exercise 1). This metric can be generalized to any dimension. For all

$$X = (x_1, x_2, \ldots, x_n),$$
$$Y = (y_1, y_2, \ldots, y_n),$$

define

$$d[X, Y] = \sqrt{(x_1 - y_1)^2 + (x_2 - y_2)^2 + \cdots + (x_n - y_n)^2}.$$

Then $(\mathbb{R}^n, d)$ is a metric space. These distance functions are known as the **standard metrics** on $\mathbb{R}^n$, and unless otherwise noted, they will be the assumed metrics for these spaces.

For another example of a metric space, let $C[a, b]$ be the set of all functions continuous on $[a, b]$ and define for all $f, g \in C[0, 1]$,

$$d[f, g] = \int_0^1 |f(x) - g(x)|\, dx.$$

This is a natural definition for the distance between two functions because the closer two functions are to each other, the smaller the area between them will be (Figure 13.1). For instance, to measure the distance between $f(x) = x^2$ and $g(x) = x$ over the interval $[0, 1]$, we compute

$$d[f, g] = \int_0^1 |x^2 - x|\, dx = 1/6.$$

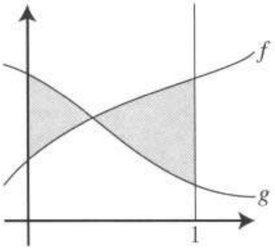

Figure 13.1 Measuring the distance between two functions using area.

Now check that $(C[0,\ 1],\ d)$ is a metric space. Since it is the most involved, we will check first that the Triangle Inequality works. Take $f,\ g,\ h \in C[0,\ 1]$ and calculate:

$$\begin{aligned}
d[f,\ g] &= \int_0^1 |f(x) - g(x)|\,dx \\
&= \int_0^1 |f(x) - h(x) + h(x) - g(x)|\,dx \\
&\leqslant \int_0^1 (|f(x) - h(x)| + |h(x) - g(x)|)\,dx \\
&= \int_0^1 |f(x) - h(x)|\,dx + \int_0^1 |h(x) - g(x)|\,dx \\
&= d[f,\ h] + d[h,\ g].
\end{aligned}$$

The inequality holds due to Equationl13.1. For the other three:

- Since $|f(x) - g(x)| \geqslant 0$ for all x,
$$d[f,\ g] = \int_0^1 |f(x) - g(x)|\,dx \geqslant 0.$$
- If $d[f,\ g] = 0$, this means that the area under the curve $y = |f(x) - g(x)|$ on the interval $[0,\ 1]$ equals 0. Since $|f(x) - g(x)|$ is never negative, the only way that this can happen is when $f = g$. Conversely, if $f = g$, then $|f(x) - g(x)| = 0$ for all x. Hence, $d[f,\ g] = 0$.
- Because $|f(x) - g(x)| = |g(x) - f(x)|$, we have that $d[f,\ g] = d[g,\ f]$.

Therefore, $(C[0,\ 1],\ d)$ is a metric space.

Open Sets

Manifolds have the property that the nearby region surrounding any point of the space resembles $\mathbb{R}^n$. In the one-dimensional case, this means that the region looks like an open interval. To generalize this to higher dimensions, we need our first definition.

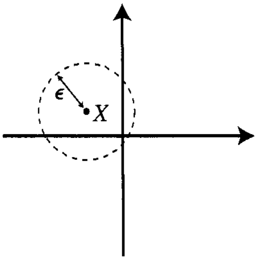

Figure 13.2 The open disk $D(x, \epsilon)$ in $\mathbb{R}^2$.

■ DEFINITION 13.1.2

Let (M, d) be a metric space and take $x \in M$. For all $\epsilon > 0$, define

$$D_M(x, \epsilon) = \{y \in M : d[x, y] < \epsilon\}.$$

This set is called an **open disk** about x in M.

If the metric space M is clear from context, we can write $D(x, \epsilon)$ for $D_M(x, \epsilon)$. For example, if $M = \mathbb{R}$ with the standard metric,

$$D(x, \epsilon) = (x - \epsilon, x + \epsilon),$$

and if $M = \mathbb{R}^2$ with the standard metric, $D(X, \epsilon)$ is the interior of a circle excluding its circumference. This is illustrated in Figure 13.2, where the dashed lines represent the exclusion of the circumference of the circle.

The open disk will allow us to make our main definition.

■ DEFINITION 13.1.3

Let M be a metric space. A subset U of M is called **open** in M if for all $x \in U$, there exists $\epsilon > 0$ such that $D_M(x, \epsilon) \subseteq U$.

We should note that for any metric space M, both M and $\varnothing$ are open. The is because $D_M(x, \epsilon)$ is a subset of M for any $x \in M$ and $\epsilon > 0$. As for the empty set, the proposition

$$\text{if } x \in \varnothing, \text{ then there exists } \epsilon > 0 \text{ such that } D_M(x, \epsilon) \subseteq \varnothing$$

is true for all x because $x \in \varnothing$ is always false (see page 38).

Here are some other examples of open sets.

- Let $a, b \in \mathbb{R}$. To prove that (a, b) is open, let $a < x < b$. We must isolate x inside an open interval within (a, b). To do this, find the distance from x to each endpoint and let ϵ be the minimum of the two distances. The notation that we will use for this is:

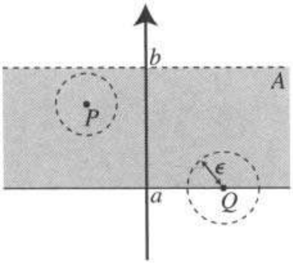

Figure 13.3 The set A is not open.

$$\epsilon = \min\{x - a,\ b - x\}.$$

Now let $y \in D(x,\ \epsilon)$. This means that $x - \epsilon < y < x + \epsilon$, and we may conclude that

$$a = x - (x - a) \leqslant x - \epsilon < y < x + \epsilon \leqslant x + (b - x) = b.$$

Therefore, $D(x,\ \epsilon) = (x - \epsilon,\ x + \epsilon) \subseteq (a,\ b)$.

- We can use the strategy of the previous example on other sets. Let A equal the set $(1,\ 2) \cup (4,\ 7)$. To show that A is open, pick a real number x such that $1 < x < 2$ or $4 < x < 7$. Define

  $$\epsilon = \min\{x - 1,\ 2 - x,\ x - 4,\ 7 - x\}.$$

  With this definition, $(x - \epsilon,\ x + \epsilon) \subseteq A$.

To show that a set A is not open in a metric space M, we must prove that there exists $x \in A$ such that $D(x,\ \epsilon)$ is not a subset of A for all $\epsilon > 0$. For this example, let $a,\ b \in \mathbb{R}$ so that $a < b$. The set

$$A = \{(x,\ y) \in \mathbb{R}^2 : a \leqslant y < b\}$$

is not open in $\mathbb{R}^2$ (Figure 13.3). Any point P that is on the interior of A can be surrounded by a disk that is a subset of A. However, this is not true for a point on the bottom border, so take Q to be $(3,\ a)$. Then for all $\epsilon > 0$,

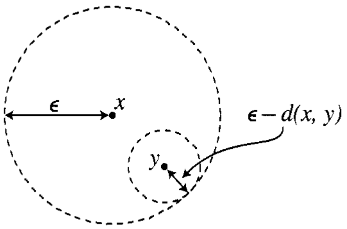
$$D((3,\ a),\ \epsilon)\backslash A \neq \varnothing$$

because $(3,\ a - \epsilon/2)$ is a member of $D((a,\ 3),\ \epsilon)$ but not of A.

Now that we have seen examples of open and nonopen sets, we should prove that the disk is actually open and justify its name. The proof is a generalization of the fact that $(a,\ b)$ is open in $\mathbb{R}$.

■ THEOREM 13.1.4

$D(x,\ \epsilon)$ is open for any x in a metric space M.



PROOF

We must show that we can isolate any element of $D(x, \epsilon)$ inside an open disk. So let $y \in D(x, \epsilon)$. The open disk about y that we want is

$$D(y, \epsilon - d[x, y]).$$

To show that this disk is included in $D(x, \epsilon)$, let $z \in D(y, \epsilon - d[x, y])$. This means that

$$d[y, z] < \epsilon - d[x, y],$$

and hence

$$d[x, z] \leqslant d[x, y] + d[y, z] < \epsilon$$

by the Triangle Inequality. We conclude that $z \in D(x, \epsilon)$. ■

An application of the definition is one way to prove that a set is open. Other ways include the next two theorems of the section.

■ THEOREM 13.1.5

Let M be a metric space.

- The union of a collection of open sets is open.
- The intersection of a finite collection of open sets is open.

PROOF

To prove the first part, let $\mathcal{F} = \{U_i : i \in I\}$ be a family of open sets. Take $x \in \bigcup \mathcal{F}$. This means that there exists $i \in I$ such that $x \in U_i$. Since U_i is open, we have $\epsilon > 0$, so that $D(x, \epsilon) \subseteq U_i$, but this implies that $D(x, \epsilon) \subseteq \bigcup \mathcal{F}$.

For the second part let $x \in U_1 \cap U_2 \cap \cdots \cap U_k$, where k is a positive integer ($k \in \mathbb{Z}^+$). By definition, x is an element of each U_i. Since each of these is open, there exists $\epsilon_i > 0$ so that $D(x, \epsilon_i)$ is a subset of U_i for $i = 1, 2, \ldots, k$. Define

$$\epsilon = \min\{\epsilon_1, \epsilon_2, \ldots, \epsilon_k\}.$$

Then $\epsilon \leqslant \epsilon_i$ for all i, and this means that $D(x, \epsilon) \subseteq D(x, \epsilon_i)$. Hence, $D(x, \epsilon)$ is a subset of the intersection. ■

To see that the finiteness condition is necessary for the intersection of open sets to be open, consider $\{(-1/n, 1/n) : n \in \mathbb{Z}^+\}$. This is a family of open sets in $\mathbb{R}$.

However,

$$\bigcap_{n=1}^{\infty}(-1/n,\ 1/n) = \{0\},$$

which is not open in $\mathbb{R}$.

The next definition relies on Theorem 13.1.5.

DEFINITION 13.1.6

If M is a metric space and A a subset of M, define

$$\text{int}(A) = \bigcup\{U : U \text{ is open in } M \text{ and } U \subseteq A\}.$$

This set is called the **interior** of A.

Since it is the union of open sets, the interior of a set A is open. Moreover, it must be the largest open subset of A (Exercise 14). As examples, $\text{int}([0,\ 1]) = (0,\ 1)$ and $\text{int}(\mathbb{Z}) = \varnothing$ in $\mathbb{R}$, because the empty set is the only open subset of $\mathbb{Z}$. In $\mathbb{R}^2$,

$$\text{int}([0,\ 1] \times [2,\ 4]) = (0,\ 1) \times (2,\ 4)$$

and

$$\text{int}(\{(x,\ y) \in \mathbb{R}^2 : xy \leqslant 1\}) = \{(x,\ y) \in \mathbb{R}^2 : xy < 1\}.$$

One way to identify the points in a set's interior is to use the next theorem.

THEOREM 13.1.7

If A is a subset of a metric space, then $x \in \text{int}(A)$ if and only if there exists $\epsilon > 0$ so that $D(x,\ \epsilon) \subseteq A$.

PROOF

First let $x \in \text{int}(A)$. This means that there exists an open subset U of A that contains x. So there exists $\epsilon > 0$ such that $D(x,\ \epsilon) \subseteq U \subseteq A$.

Conversely, if $D(x,\ \epsilon) \subseteq A$ for some $\epsilon > 0$, then x must be an element of the interior because $D(x,\ \epsilon)$ is open. ■

For instance, define $\mathbb{Z} = \{\ldots,\ -2,\ -1,\ 0,\ 1,\ 2,\ \ldots\}$ and view it as a metric space with the standard metric from $\mathbb{R}$. Let $A = \{2k : k \in \mathbb{Z}\}$, the set of even integers. The interior of A is A. To see this, let $n \in \mathbb{Z}$. Then

$$D_{\mathbb{Z}}(2n,\ 1) = \{m \in \mathbb{Z} : |2n - m| < 1\} = \{2n\}.$$

Therefore, $2n \in \text{int}(A)$, which implies that $A \subseteq \text{int}(A)$. Since we already know that $\text{int}(A) \subseteq A$, we conclude that $\text{int}(A) = A$. This means that A is open in $\mathbb{Z}$.

Closed Sets

The difference between an open interval and a closed one lies with the endpoints. Open intervals do not contain the endpoints. Instead, the endpoints belong to the complement of the open interval. A closed interval will contain its endpoints. We will take this idea and define what it means for a set to be closed in an arbitrary metric space and then prove some results.

DEFINITION 13.1.8

A subset A of a metric space M is **closed** in M if $M \backslash A$ is open in M.

Both M and $\varnothing$ are closed because $M \backslash M = \varnothing$ and $M \backslash \varnothing = M$ and both of these are open. Letting $A^c = M \backslash A$, here are some examples of closed sets.

- $[a, b]$ is closed in $\mathbb{R}$ for all real numbers $a < b$.
- Since $D(x, \epsilon)$ is open, $D(x, \epsilon)^c$ is closed.
- In $\mathbb{R}^2$ the set $\{(x, y) \in \mathbb{R}^2 : xy \geqslant 1\}$ is closed.

There are sets that are neither open nor closed. In $\mathbb{R}$, $(0, 1]$ provides a simple example. The set $A = \{(x, y) \in \mathbb{R}^2 : a \leqslant x < b\}$ is such an example in $\mathbb{R}^2$. Here is a more interesting one. Let $A = \{1/k : k \in \mathbb{Z}^+\}$.

- To see that A is not open, let n be a positive integer and consider
$$D(1/n, \epsilon) = (1/n - \epsilon, 1/n + \epsilon)$$
for any $\epsilon > 0$. Since there exists $m \in \mathbb{R}$ such that
$$\max\left\{\frac{1}{n+1}, \frac{1}{n} - \epsilon\right\} < m < \frac{1}{n},$$
$m \in D(1/n, \epsilon)$ but $m \notin A$. Hence, A is not open.
- To check that A is not closed, we show that A^c is not open. Suppose that $\epsilon > 0$. Then there exists a positive integer n such that $1/n < \epsilon$. Thus, $D(0, \epsilon) \cap A \neq \varnothing$, which means that $D(0, \epsilon)$ is not a subset of A^c even though $0 \in A^c$.

We shall see shortly that there is another way to show that $\{1/n : n \in \mathbb{Z}^+\}$ is not closed.

To emphasize the point of the examples, remember that although the complement of an open set is closed and the complement of a closed set is open, the terms are not negations of each other. There are sets that are both open and closed, and there are sets that are neither. Hence, we cannot show that a set is closed by proving that it is not open. Similarly, we cannot show that a set is open by showing that it is not closed. However, for the closed case the next theorems can help.

THEOREM 13.1.9

In any metric space:

- The intersection of a collection of closed sets is closed.
- The union of a finite collection of closed sets is closed.

PROOF

Let $\{C_i : i \in I\}$ be a family of closed sets. To prove that $\bigcap_{i\in I} C_i$ is closed, we must show that its complement is open. Since each C_i is closed, C_i^{c} is open. Therefore,

$$\left(\bigcap_{i\in I} C_i\right)^{\mathrm{c}} = \bigcup_{i\in I} C_i^{\mathrm{c}}$$

is open by Theorem 13.1.5.

Similarly, if I is a finite index set equal to $\{1, 2, \ldots, k\}$, then

$$C_1 \cup C_2 \cup \cdots \cup C_k$$

is closed because its complement

$$C_1^{\mathrm{c}} \cap C_2^{\mathrm{c}} \cap \cdots \cap C_k^{\mathrm{c}}$$

is open. ■

The largest open set within a set is its interior. Corresponding to this is the smallest closed set that contains a given set. This is our next definition.

■ DEFINITION 13.1.10

Let A be a subset of a metric space M. Define

$$\mathrm{cl}(A) = \bigcap\{F : F \text{ is closed in } M \text{ and } A \subseteq F\}$$

and call this set the **closure** of A.

In $\mathbb{R}$, $\mathrm{cl}((0, 1)) = [0, 1]$ and $\mathrm{cl}(\mathbb{Z}) = \mathbb{Z}$. In $\mathbb{R}^2$,

$$\mathrm{cl}((0, 1) \times (2, 4)) = [0, 1] \times [2, 4]$$

and

$$\mathrm{cl}(\{(x, y) \in \mathbb{R}^2 : xy < 1\}) = \{(x, y) \in \mathbb{R}^2 : xy \leqslant 1\}.$$

We note that the closure of a set is closed. To see this, examine the complement of $\mathrm{cl}(A)$:

$$\mathrm{cl}(A)^{\mathrm{c}} = \left(\bigcap\{F : F \text{ is closed and } A \subseteq F\}\right)^{\mathrm{c}} = \bigcup\{F^{\mathrm{c}} : F \text{ is closed and } A \subseteq F\}.$$

Since each F is closed, each F^{c} is open. Therefore, the union is open (Theorem 13.1.5). We should also note that a set A is closed in a metric space M if and only if $\mathrm{cl}(A) = A$. The proof of this is left as Exercise 15.

The way to picture a closed set is to think of it like a closed interval. A closed set contains all of the points of its interior plus all of the points that form a boundary around its interior. We therefore need a definition that will name all of these points.

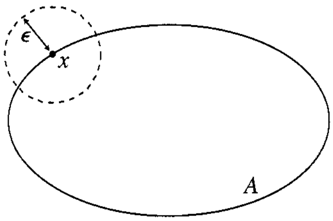


Figure 13.4 x is an accumulation point of A.

■ DEFINITION 13.1.11

Let A be a subset of a metric space M. An element $x \in M$ is an **accumulation point** of A if for all $\epsilon > 0$,

$$(D(x, \epsilon)\backslash\{x\}) \cap A \neq \varnothing.$$

Basically, an accumulation point of a set A has the property that there are points in A that are arbitrarily close to it (see Figure 13.4). We exclude the accumulation point from the criterion since it is always very close to itself!

Here is an example. Define $A = \{(x, y) \in \mathbb{R}^2 : 0 < x < 2\}$. The interior point $(1, 0)$ is an accumulation point. To prove that $(0, 0)$ is also an accumulation point, let $\epsilon > 0$ and take $a \in \mathbb{R}$ so that $0 < a < \min\{1, \epsilon\}$. Then,

$$(a, 0) \in [D((0, 0), \epsilon)\backslash\{(0, 0)\}] \cap A,$$

which means that the desired intersection is nonempty.

The last example shows that an accumulation point need not be an element of the set. In the metric space $\mathbb{R}$, we see that 0 is an accumulation point for both $(0, 1)$ and $[0, 1]$. For $\mathbb{R}^2$, $(1, 0)$ is an accumulation point for the open disk

$$\{(x, y) \in \mathbb{R}^2 : x^2 + y^2 < 1\}$$

and the line

$$\{(x, x - 1) : x \in \mathbb{R}\}.$$

On the other hand, a set need not have any accumulation points. Take the metric space $\mathbb{Z} \times \mathbb{Z}$ with the standard metric from $\mathbb{R}^2$. Then for all $a, b \in \mathbb{Z}$, (a, b) cannot be an accumulation point because

$$D_{\mathbb{Z}\times\mathbb{Z}}((a, b), 1/2)\backslash\{(a, b)\} = \varnothing.$$

We are now ready for our last test for closure.

■ THEOREM 13.1.12

A set is closed if and only if it contains its accumulation points.

PROOF

Let A be a subset of a metric space M. Assume that A is closed. Let x be an accumulation point of A. To obtain a contradiction, assume that $x \notin A$. This means that $x \in A^{\mathrm{C}}$, but this set is open. Hence, there is an $\epsilon > 0$ with the property that $D(x, \epsilon) \subseteq A^{\mathrm{C}}$. Therefore,

$$D(x, \epsilon) \cap A = \varnothing,$$

contradicting the fact that x is an accumulation point.

Now suppose that A contains all its accumulation points. We must show that A^{C} is open. Take $x \in A^{\mathrm{C}}$. By hypothesis, x cannot be an accumulation point of A. This means that there exists $\epsilon > 0$ such that $D(x, \epsilon) \cap A = \varnothing$. Therefore, $D(x, \epsilon)$ is a subset of A^{C}. ■

Exercises

Let (M, d) be a metric space.

1. Prove that $\mathbb{R}$, $\mathbb{R}^2$, and $\mathbb{R}^n$ when paired with the standard metrics are metric spaces.

2. Prove that for all $x, y \in M$ such that $x \neq y$, there exists $\epsilon > 0$ such that $D(x, \epsilon) \cap D(y, \epsilon) = \varnothing$.

3. Suppose that $\epsilon_1 \leqslant \epsilon_2$. Prove for any $x \in M$, $D(x, \epsilon_1) \subseteq D(x, \epsilon_2)$.

4. Define

$$d'(x, y) = \frac{d[x, y]}{1 + d[x, y]}.$$

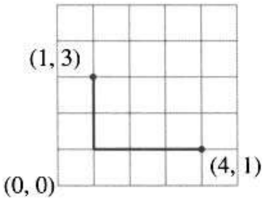
Show that d' is a metric on M.

5. For all $x, y \in M$, let $d[x, y] = 0$ if and only if $x = y$, else $d[x, y] = 1$. Show that d is a metric on M.

6. Define the following metric on $\mathbb{R}^2$: For all $(x, y), (x', y') \in \mathbb{R}^2$,

$$d[(x, y), (x', y')] = |x - x'| + |y - y'|.$$

Let $N = \{(x, y) : x, y \in \mathbb{Z} \text{ and } x, y \geqslant 0\}$. Show that (N, d) is a metric space. (The function d is called the **taxicab** metric on N because N is viewed as the grid of a downtown area like Chicago. If a taxi is boarded at intersection $(1, 3)$ and ridden to intersection $(4, 1)$, the total number of blocks traveled is $|1 - 4| + |3 - 1| = 5$.)



7. Sometimes a set will be open in one metric space but not open in another. Let A be the set of points that lie on the real line between 1 and 2, exclusive.
   (a) Explain why A is open in $\mathbb{R}$.
   (b) Describe A as a subset of $\mathbb{R}^2$.
   (c) Explain why A is not open in $\mathbb{R}^2$.

8. Prove that the following are open in the metric spaces indicated. Assume the usual metric for each space.
   (a) $\mathbb{R}\backslash\{0\}$ in $\mathbb{R}$
   (b) $\mathbb{R}^2\backslash\{(0, 0)\}$ in $\mathbb{R}^2$
   (c) $\mathbb{R}^2\backslash\{(x, y) \in \mathbb{R}^2 : y = 2x - 1\}$ in $\mathbb{R}^2$
   (d) $\{(x, y) \in \mathbb{R}^2 : x + y < 1\}$ in $\mathbb{R}^2$
   (e) $\{(x, y, z) \in \mathbb{R}^3 : x^2 + y^2 < 1\}$ in $\mathbb{R}^3$

9. Prove that $\{(x, y) \in \mathbb{R}^2 : a < x < b\}$ is open in $\mathbb{R}^2$.

10. Prove that every subset of M is open if and only if $\{a\}$ is open for all $a \in M$.

11. View $\mathbb{R}$ as a metric space with the standard metric. Verify Theorem 13.1.5 by directly proving the following propositions.
   (a) $\displaystyle\bigcup_{n=1}^{\infty} D(0, 1/n)$ is open.
   (b) $\displaystyle\bigcap_{n=1}^{k} D(0, 1/n)$ is open for all $k \in \mathbb{Z}^+$.
   (c) $\displaystyle\bigcap_{n=1}^{\infty} D(0, 1/n)$ is not open.

12. Describe the interior of each of the following subsets of $\mathbb{R}$: $\{0\}$, $(0, 2]$, $[0, 2]$, and $(0, 2) \cup \{-1, 3\}$.

13. Describe the interior of each of the given sets in $\mathbb{R}^2$:
   (a) $\{(x, y) \in \mathbb{R}^2 : x^2 + y^2 < 1\}$
   (b) $\{(x, y) \in \mathbb{R}^2 : x^2 + y^2 \leqslant 1\}$
   (c) $\{(x, y) \in \mathbb{R}^2 : y \leqslant 1/x\}$

14. Let $A \subseteq M$. Show that $\text{int}(A)$ is the largest open subset of A by proving that if $U \subseteq A$ is open, then $U \subseteq \text{int}(A)$.

15. Let M be a metric space. Prove that $A \subseteq M$ is closed in M if and only if $\text{cl}(A) = A$.

16. Let $x \in M$. Prove $\{x\}$ is closed in M.

17. Show that the following are closed in the given metric spaces.
   (a) $\{0\}$ in $\mathbb{R}$
   (b) $\{(0, 0)\}$ in $\mathbb{R}^2$

(c) $\{(x, y) \in \mathbb{R}^2 : y = 2x - 1\}$ in $\mathbb{R}^2$
(d) $\{(x, y) \in \mathbb{R}^2 : 5 \leqslant x \leqslant 7\}$ in $\mathbb{R}^2$
(e) $\{(x, y) \in \mathbb{R}^2 : x + y \leqslant 1\}$ in $\mathbb{R}^2$
(f) $\{(x, y, 1) : x, y \in \mathbb{R}\}$ in $\mathbb{R}^3$

18. Let $A \subseteq M$. Show that $A \setminus \text{int}(A)$ is closed.

19. Take $a \in M$. Prove that $\{b \in M : d[a, b] \leqslant 1\}$ is closed using both the definition and Theorem 13.1.12.

20. Let $A \subseteq B \subseteq M$. Prove that if a is an accumulation point of A, it is an accumulation point of B.

21. Suppose that A and B are subsets of M. Prove the following about the closure:
   (a) $A \subseteq \text{cl}(A)$.
   (b) If $A \subseteq B$, then $\text{cl}(A) \subseteq \text{cl}(B)$.
   (c) $\text{cl}(\varnothing) = \varnothing$.
   (d) $\text{cl}(A) = \text{cl}(\text{cl}(A))$.
   (e) $\text{cl}(A)^{\text{C}} = \text{int}(A^{\text{C}})$.

22. Describe the set of accumulation points of each of the following as subsets of the given metric space:
   (a) $(0, 2)$ in $\mathbb{R}$
   (b) $(0, 2]$ in $\mathbb{R}$
   (c) $(0, 2) \cup \{-1, 3\}$ in $\mathbb{R}$
   (d) $\{(x, y) \in \mathbb{R}^2\ x^2 + y^2 < 1\}$ in $\mathbb{R}^2$

23. Let f be a continuous function on $[0, 1]$. Prove that $\{f \in C[0, 1] : \|f\| < 1\}$ is open in $C[0, 1]$ with the metric defined on page 446, and the **norm** $\|f\|$ defined by

$$\|f\| = \int_0^1 |f(x)|\, dx.$$

13.2 TOPOLOGICAL SPACES

Let us begin by recalling the definition of a continuous function from calculus. Suppose that $f : \mathbb{R} \to \mathbb{R}$ is continuous at $x = x_0$. This means that for all real numbers x and $\epsilon > 0$, there exists $\delta > 0$ such that

$$\text{if } |x - x_0| < \delta, \text{ then } |f(x) - f(x_0)| < \epsilon. \tag{13.2}$$

Let d be the standard metric on $\mathbb{R}$ and observe that we may write Sentence 13.2 as

$$\text{if } d[x, x_0] < \delta, \text{ then } d[f(x), f(x_0)] < \epsilon. \tag{13.3}$$

However, the x values that satisfy $d[x, x_0] < \delta$ are exactly the elements of $D(x_0, \delta)$. Therefore, we may rewrite Sentence 13.3 as

$$\text{if } x \in D(x_0, \delta), \text{ then } f(x) \in D(f(x_0), \epsilon). \tag{13.4}$$

These three sentences all describe continuity based on the standard metric on $\mathbb{R}$. To generalize the definition of continuity to other metric spaces, all that is needed is to drop the assumption that d is the standard metric. Sentences 13.3 and 13.4 are then definitions for continuity in any metric space. However, can we generalize further and define what it means for a function to be continuous without using a metric? Consider the following. Let $f : M \to N$ be a function where (M, d) and (N, d') are metric spaces. Assume that for all subsets V of N,

$$\text{if } V \text{ is an open in } N\text{, then } f^{-1}[V] \text{ is open in } M. \tag{13.5}$$

The set $f^{-1}[V] = \{x \in M : f(x) \in V\}$ is called the **inverse image** of V under f. We will now show that Sentence 13.5 is equivalent to Sentence 13.4.

- Assume Sentence 13.4 holds for all elements of M. Let V be open in N. To show that $f^{-1}[V]$ is open in M, take $x_0 \in f^{-1}[V]$. This means that $y_0 = f(x_0)$ is an element of V. Since V is open in N, there exists $\epsilon > 0$ such that $D_N(y_0, \epsilon) \subseteq V$. By hypothesis there exists $\delta > 0$ so that for all x,

  $$\text{if } x \in D_M(x_0, \delta)\text{, then } f(x) \in D_N(y_0, \epsilon).$$

  However, letting a be an element of $D_M(x_0, \delta)$, we find that $f(a)$ is an element of $D_N(y_0, \epsilon)$, which is a subset of V. Thus, $a \in f^{-1}[V]$, and this shows that we have $D_M(x_0, \delta) \subseteq f^{-1}[V]$.

- Now suppose that Sentence 13.5 is true. Let $x_0 \in M$ and $\epsilon > 0$. Write $y_0 = f(x_0)$. Since $D_N(y_0, \epsilon)$ is open in N, we know that $f^{-1}[D_N(y_0, \epsilon)]$ is open in M. Thus, we have $D_M(x_0, \delta) \subseteq f^{-1}[D_N(y_0, \epsilon)]$ for some $\delta > 0$. This is the δ that we want because if $x \in D_M(x_0, \delta)$, then $x \in f^{-1}[D_N(y_0, \epsilon)]$, and this means that $f(x) \in D_N(y_0, \epsilon)$.

Since the metric definition of continuity is equivalent to the definition given in Sentence 13.5, we may use the new sentence instead. Furthermore, notice that the new definition only requires an examination involving the open sets of the space. Therefore, a complete generalization of the concept of continuity will involve excluding the metric from the space in favor of an identification of the space's open sets. For this reason we make the following definition.

■ DEFINITION 13.2.1

Let X be a nonempty set. A collection $\mathcal{T}$ of subsets of X is called a **topology** on X if:

- $\varnothing$ and X are both elements of $\mathcal{T}$.
- the union of every collection of sets from $\mathcal{T}$ is an element of $\mathcal{T}$.
- the intersection of every finite collection of sets from $\mathcal{T}$ is again in $\mathcal{T}$.

The pair $(X, \mathcal{T})$ is called a **topological space**. The subsets found in $\mathcal{T}$ are defined to be the **open** sets of X, and the elements of X are called **points**.

The definition is chosen so that the metric space (M, d) can be viewed naturally as a topological space. Define $\mathcal{T}$ to be the open sets of M in the sense of Definition 13.1.3. Then by Theorem 13.1.5, $\mathcal{T}$ is a topology on M. A topology defined on a metric space M in this manner is called the **induced topology** on M.

Another example is the **discrete topology**. Let X be a set and let $\mathcal{T}$ be the set of subsets of X. Since the union and intersection of subsets of X is a subset of X, $\mathcal{T}$ is a topology on X. On the other extreme, if $\mathcal{T}' = \{\varnothing, X\}$, then $\mathcal{T}'$ is the smallest possible topology on X and is called the **trivial topology**. A more general example is the next theorem.

■ THEOREM 13.2.2

The intersection of two topologies on a set X is a topology on X.

PROOF

Let X be a set and $\mathcal{T}$ and $\mathcal{T}'$ be topologies on X. To show that $\mathcal{T} \cap \mathcal{T}'$ is a topology on X, we must check the three conditions.

- $X, \varnothing \in \mathcal{T} \cap \mathcal{T}'$ since $X, \varnothing \in \mathcal{T}$ and $X, \varnothing \in \mathcal{T}'$.
- Let $\mathcal{F} \subseteq \mathcal{T} \cap \mathcal{T}'$. Then, $\mathcal{F} \subseteq \mathcal{T}$ and $\mathcal{F} \subseteq \mathcal{T}'$. Therefore, $\bigcup \mathcal{F} \in \mathcal{T}$ and $\bigcup \mathcal{F} \in \mathcal{T}'$, and we conclude that
$$\bigcup \mathcal{F} \in \mathcal{T} \cap \mathcal{T}'.$$
- Let $\{U_1, U_2, \ldots, U_k\} \subseteq \mathcal{T} \cap \mathcal{T}'$. From this $U_i \subseteq \mathcal{T}$ and $U_i \subseteq \mathcal{T}'$ for all i. Therefore,
$$U_1 \cap U_2 \cap \cdots \cap U_k \in \mathcal{T},$$
and
$$U_1 \cap U_2 \cap \cdots \cap U_k \in \mathcal{T}'.$$
Hence,
$$U_1 \cap U_2 \cap \cdots \cap U_k \in \mathcal{T} \cap \mathcal{T}'. \blacksquare$$

Our generalization of continuity is complete with the next definition.

■ DEFINITION 13.2.3

Let X and Y be topological spaces. A function $f : X \to Y$ is called **continuous** when $f^{-1}[V]$ is open in X for all open subsets V of Y.

From our work above, any function between metric spaces that is continuous under the metric definition is continuous under the topological definition provided that the set has the induced topology.

For another example, let X be a set and let $f : X \to X$ be a function. View X as a topological space using the discrete topology. Let V be a subset of X. Under the discrete topology, since every subset of X is open, both V and $f^{-1}[V]$ are open. Therefore, in this case every function on X is continuous. This is also true when X

is given the trivial topology. Since only $\varnothing$ and X are the only open sets in X using this topology, $f^{-1}[X] = X$ and $f^{-1}[\varnothing] = \varnothing$ show that f is continuous.

We know from calculus that the composition of two continuous functions is continuous. The same result holds for the topological definition.

■ THEOREM 13.2.4

The composition of continuous functions is a continuous function.

PROOF

Let X, Y, and Z be topological spaces. Assume that $f : X \to Y$ and $g : Y \to Z$ are continuous functions. Let $V \subseteq Z$. We first observe that

$$(g \circ f)^{-1}[V] = f^{-1}[g^{-1}[V]].$$

To prove this, let $x \in (g \circ f)^{-1}[V]$. This means that there exists $z \in V$ such that $g(f(x)) = z$. Let $y = f(x)$ and write $z = g(y)$. Therefore, $y \in g^{-1}[V]$, and we conclude that $x \in f^{-1}[g^{-1}[V]]$. The other inclusion is left for Exercise 1.

To prove that the composition is continuous, let $V \subseteq Z$ be open. Since g is continuous, $g^{-1}[V]$ is open in Y, and since f is continuous, $f^{-1}[g^{-1}[V]]$ is open in X, so $(g \circ f)^{-1}[V]$ is open in X. Therefore, the composition is continuous. ■

We need one more test for continuity. We start by observing that the open disks of a metric space serve as the building block for all of the open sets of the metric space. To understand what this means in general, let X be a metric space and $\mathcal{B}$ the set of open disks in X. Let U be an open subset of X. For all $x \in X$, there exists $\epsilon_x > 0$ such that $D(x, \epsilon_x) \subseteq U$. Then

$$U = \bigcup_{x \in U} D(x, \epsilon_x). \tag{13.6}$$

Therefore, every open subset of X is the union of sets in $\mathcal{B}$. We now generalize this idea to topological sets.

■ DEFINITION 13.2.5

Let $(X, \mathcal{T})$ be a topological space. An **open base** for X is a set $\mathcal{B}$ with the property that every open set in $\mathcal{T}$ is the union of sets of $\mathcal{B}$. The sets of $\mathcal{B}$ are called **basic open sets**.

The reason that we need an open base is that it will make showing that a function is continuous more straightforward.

■ THEOREM 13.2.6

Let X and Y be topological spaces and $f : X \to Y$ a function. If $\mathcal{B}$ is an open base for Y, f is continuous if and only if the inverse image of each basic open set in $\mathcal{B}$ is open in X.

PROOF

Since sufficiency is clear, we shall let $\mathcal{B}$ be an open base for Y such that for all $B \in \mathcal{B}$, $f^{-1}[B]$ is open in X. To prove that f is continuous, take V to be an open subset of Y. Then there exists $\{B_i : i \in I\} \subseteq \mathcal{B}$ such that $V = \bigcup_{i\in I} B_i$. Thus,

$$f^{-1}[V] = f^{-1}\left[\bigcup_{i\in I} B_i\right] = \bigcup_{i\in I} f^{-1}[B_i].$$

Since the union of opens sets is open, $f^{-1}[V]$ is open. ■

Homeomorphisms

We should note that simply because $f : X \to Y$ is continuous and a one-to-one correspondence, it need not be the case that f^{-1} is continuous. If it is, by definition $f[U]$ is open for every open subset U of X. This is because $(f^{-1})^{-1} = f$. In this case we say that f **preserves** open sets and call f an **open mapping**.

■ **DEFINITION 13.2.7**

A **homeomorphism** is a continuous, one-to-one correspondence between two topological spaces that preserves open sets.

If there exists a homeomorphism between the topological spaces $(X, \mathcal{T})$ and $(Y, \mathcal{T}')$, we say that X and Y are **homeomorphic**. What this means is that the sets are the same size, or have the same **cardinality**, because there is a one-to-one correspondence between them, and there is a correspondence between the two spaces that associates the open sets of the one space with the open sets of the other. Essentially the two spaces look the same as topological spaces. For example, the function

$$f : (0, 1) \to \mathbb{R}$$

defined by $f(x) = \cot \pi x$ is a homeomorphism. We also have the following, whose proof we leave to Exercise 10.

■ **THEOREM 13.2.8**

The inverse of a homeomorphism is a homeomorphism. The composition of homeomorphisms is a homeomorphism.

We need an observation for our last definition. Let $(X, \mathcal{T})$ be a topological space and $Y \subseteq X$. Define

$$\mathcal{T}' = \{Y \cap U : U \in \mathcal{T}\}.$$

This set is a topology on Y. We will check the details:

- Since $Y = Y \cap X$ and $\varnothing = Y \cap \varnothing$, both Y and $\varnothing$ are elements of $\mathcal{T}'$.
- Let $\{U_i : i \in I\}$ be a collection of open sets from $\mathcal{T}$. Then because

$$\bigcup_{i\in I}(Y \cap U_i) = Y \cap \bigcup_{i\in I} U_i$$

and $\bigcup_{i\in I} U_i \in \mathcal{T}$, we have $\bigcup_{i\in I}(Y \cap U_i) \in \mathcal{T}'$.

- Now let $U_1, U_2, \ldots, U_k$ be sets in $\mathcal{T}$. Because
  $(Y \cap U_1) \cap (Y \cap U_2) \cap \cdots \cap (Y \cap U_k) = Y \cap (U_1 \cap U_2 \cap \cdots \cap U_k)$
  and $U_1 \cap U_2 \cap \cdots \cap U_k \in \mathcal{T}$, we may conclude that
  $$(Y \cap U_1) \cap (Y \cap U_2) \cap \cdots \cap (Y \cap U_k) \in \mathcal{T}'.$$

$\mathcal{T}'$ is called the **relative topology** on Y, and Y is said to be a **subspace** of X. Therefore, every subset of a topological space can itself be viewed as a topological space with the relative topology. Also, if $f : X \to Z$ is continuous, then $g : Y \to Z$ is also continuous when we define $g(x) = f(x)$ for all $x \in Y$. However, there is no reason to expect g to be a homeomorphism when f is.

We need the concept of a homeomorphism to make the last definition of the section.

■ DEFINITION 13.2.9

A topological space X is **Euclidean** if it is homeomorphic to a subspace of $\mathbb{R}^n$.

We may then define a topological space X to be **locally Euclidean** if for all $x \in X$, there exists a Euclidean open set containing x. A **manifold** is a locally Euclidean topological space. Examples of spaces that are manifolds include the conic sections and surfaces of spheres, tori, conoids, and spheroids.

Exercises

Unless otherwise noted, $(X, \mathcal{T})$ *and* $(Y, \mathcal{T}')$ *are topological spaces and* $\mathbb{R}^n$ *has the induced topology.*

1. Let X, Y, and Z be sets. If $f : X \to Y$ and $f : Y \to Z$ are functions, then for all subsets V of Z,
$$f^{-1}[g^{-1}[V]] \subseteq (g \circ f)^{-1}[V].$$

2. Let $\mathcal{T}$ and $\mathcal{T}'$ be topologies on X. Give an example which shows that $\mathcal{T} \cup \mathcal{T}'$ may not be a topology on X.

3. Take X to be $\{a, b, c\}$ and $\mathcal{T} = \{\varnothing, \{a\}, \{a, b\}, X\}$. Check that $(X, \mathcal{T})$ is a topological space and find all other topologies on X.

4. Let $Z \subseteq Y \subseteq X$. Let $\mathcal{S}$ be the topology of Z relative to X and $\mathcal{S}'$ the topology of Z relative to Y. Show that $\mathcal{S} = \mathcal{S}'$.

5. Confirm that $\mathcal{T} = \{U : \mathbb{R}\backslash U \text{ is finite}\} \cup \{\varnothing\}$ is a topology on $\mathbb{R}$.

6. Let $f, g : \mathbb{R} \to \mathbb{R}$ be two continuous functions. Prove that $f + g$ and fg are continuous using the metric definition of continuity. Can the topological definition be used for this problem?

7. Suppose that f, $g : \mathbb{R} \to \mathbb{R}$ are continuous functions. Prove using the metric definition of continuity that $f \circ g$ is continuous.

8. Prove Equation 13.6.

9. Let $\mathcal{B} \subseteq \mathbb{R}^2$ be the set of open squares, so

$$\mathcal{B} = \{(a, b) \times (c, d) : a < b, c < d\},$$

where × denotes the Cartesian product. Prove that $\mathcal{B}$ is an open base for $\mathbb{R}^2$.

10. Prove Theorem 13.2.8.

11. Find an example of a continuous one-to-one correspondence between topological spaces that is not a homeomorphism.

12. Let $\mathcal{B}$ be an open base for X. Prove that $f : X \to Y$ is an open mapping if and only if $f[U]$ is open for all $U \in \mathcal{B}$.

13. Suppose that $\mathcal{B} = \{U_i : i \in I\}$ and $\mathcal{B}' = \{U_i' : i \in I\}$ are open bases for X and Y, respectively. Prove that if f is a one-to-one correspondence such that $f[U_i] = U_i'$, then f is a homeomorphism.

14. Show that $\{(x, x^2) : x \in \mathbb{R}\}$ is homeomorphic to $\mathbb{R}$ by finding two bases and a homeomorphism as described in the previous problem.

15. Show that $(0, 1)$ is homeomorphic to both $(5, 6)$ and $\mathbb{R}$.

16. Let $\mathcal{C} = \{(x, y, z) \in \mathbb{R}^3 : x^2 + y^2 = 1\}$ be a subset of $\mathbb{R}^3$.
    (a) Give a geometric description for $\mathcal{C}$.
    (b) Show that $\mathcal{C} \setminus \{(1, 0, z) : z \in \mathbb{R}\}$ is homeomorphic to $(-1, 1) \times \mathbb{R}$.
    (c) Is $\mathcal{C}$ homeomorphic to $(-1, 1) \times \mathbb{R}$ or even $\mathbb{R}^2$? Explain.

17. Define a subset C of X to be **closed** in X if $X \setminus C$ is open. Prove:
    (a) X and $\varnothing$ are closed.
    (b) The intersection of closed sets is closed.
    (c) The union of finitely many closed sets is closed.

18. Let $f : X \to Y$ be a homeomorphism. Show:
    (a) If C is closed in X, then $f[C]$ is closed in Y.
    (b) If C is closed in Y, then $f^{-1}[C]$ is closed in X.

19. The **closure** of a subset A of X is the intersection of all closed subsets of X that contain A. This is the same definition as for metric spaces (Definition 13.1.10). Prove that A is closed if and only if $\text{cl}(A) = A$.

20. Let $f : X \to Y$ be a function. Prove that the following are equivalent:
    (a) f is continuous.
    (b) $f^{-1}[F]$ is closed in X for all F closed in Y.
    (c) $f[\text{cl}(A)] \subseteq \text{cl}(f[A])$ for each $A \subseteq X$.
    (d) $\text{cl}(f^{-1}[B]) \subseteq f^{-1}[\text{cl}(B)]$ for each $B \subseteq Y$.

13.3 STEREOGRAPHIC PROJECTION

Because of Exercise 16(b) of Section 13.2, we know that the surface of a cylinder is locally Euclidean. Therefore, it is a manifold. Like the cylinder, the surface of a sphere is also a locally Euclidean topological space, making it a manifold.

Take a sphere with center O and radius $\overline{ON}$. Construct $\overline{OU}$ and $\overline{OV}$ such that $\overline{ON}$, $\overline{OU}$, and $\overline{OV}$ are perpendicular to each other, setting up a coordinate system with O as the origin, $\overline{OU}$ as the x-axis, $\overline{OV}$ as the y-axis, and $\overline{ON}$ as the z-axis, as in Figure 13.5. With these axes the equation for the sphere is

$$x^2 + y^2 + z^2 = r^2, \tag{13.7}$$

where $r = ON$. Let $\mathcal{S}$ be the surface of the sphere without N and let $\mathcal{P}$ be the xy-plane. So we have

$$\mathcal{S} = \left\{ \left(x,\ y,\ \pm\sqrt{r^2 - x^2 - y^2} \right) : x \neq 0 \text{ or } y \neq 0 \right\} \cup \{(0,\ 0,\ -r)\}$$

and

$$\mathcal{P} = \{(x,\ y,\ 0) : x,\ y \in \mathbb{R}\}.$$

We wish to define a one-to-one correspondence between the points on the sphere (excluding N) and the points on the plane.

■ DEFINITION 13.3.1

A **stereographic projection** of a sphere $\mathcal{S}$ with **center of projection** N and **plane of projection** $\mathcal{P}$ is a function $\phi : \mathcal{S} \to \mathcal{P}$ that associates every point P on $\mathcal{S}$ with the point P' on $\mathcal{P}$ such that N, P, and P' are collinear.

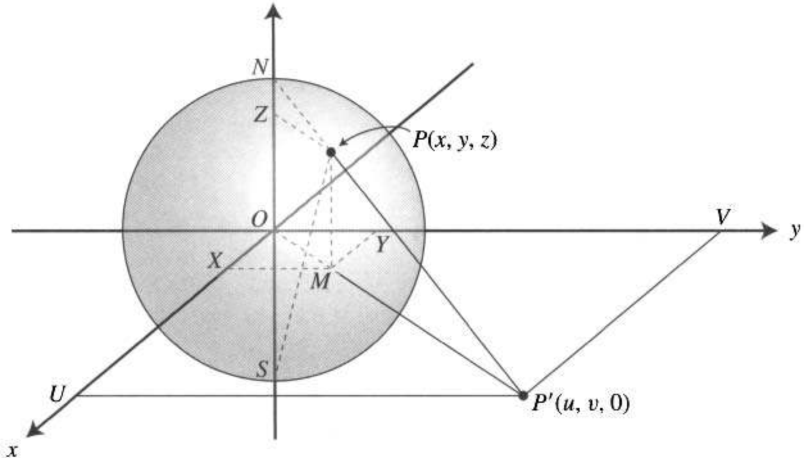


Figure 13.5 The stereographic projection maps P to P'.

Transformation Equations

We will follow Sommerville (1958, 172–174). Let N have coordinates $(0,\ 0,\ r)$ and S have coordinates $(0,\ 0,\ -r)$ using the labels of Figure 13.5. Let $\phi(P) = P'$, where P has coordinates $(x,\ y,\ z)$ and P' has $(u,\ v,\ 0)$. Because $\triangle OUP'$ is similar to $\triangle OXM$, we have

$$\frac{u}{x} = \frac{v}{y} = \frac{OP'}{OM},$$

and if we take Z on $\overline{NS}$ such that $\overline{ZP}$ is parallel to $\overline{OM}$,

$$\frac{OP'}{OM} = \frac{OP'}{ZP} = \frac{NP'}{NP} = \frac{NO}{NZ} = \frac{r}{r-z}$$

because $\triangle NOP' \sim \triangle NZP$ and $\overline{OM} \cong \overline{ZP}$. Observe that since $\sphericalangle NPS$ and $\sphericalangle NOP'$ are right angles, $\triangle NPS$ is similar to $\triangle NOP'$. Therefore,

$$NP \cdot NP' = NO \cdot NS = 2r^2.$$

Solving for NP' and substituting, we find that

$$\frac{NP'}{NP} = \frac{2r^2}{NP^2} = \frac{2r^2}{OM^2 + NZ^2} = \frac{2r^2}{x^2 + y^2 + (r-z)^2}.$$

Similarly, when we solve for NP we conclude that

$$\frac{NP'}{NP} = \frac{(NP')^2}{2r^2} = \frac{(OP')^2 + ON^2}{2r^2} = \frac{u^2 + v^2 + r^2}{2r^2}.$$

Therefore,

$$\frac{u}{x} = \frac{v}{y} = \frac{2r^2}{x^2 + y^2 + (r-z)^2} \tag{13.8}$$

and

$$\frac{u}{x} = \frac{v}{y} = \frac{r}{r-z} = \frac{u^2 + v^2 + r^2}{2r^2}, \tag{13.9}$$

These two equations can be used to give us parametric equations that will allow us to transform a point on the sphere to the projected point on the plane, and conversely. In particular, if $(x,\ y,\ z)$ is any point on the sphere other than N and $(u,\ v,\ 0)$ is its projection, then by solving for x, y, and z in Equation 13.9, we obtain

$$x = \frac{2r^2 u}{u^2 + v^2 + r^2}, \tag{13.10}$$

$$y = \frac{2r^2 v}{u^2 + v^2 + r^2}, \tag{13.11}$$

$$z = \frac{r(u^2 + v^2 + r^2) - 2r^3}{u^2 + v^2 + r^2}, \tag{13.12}$$

and by using Equation 13.8 we see that the stereographic projection ϕ is given by the equation

$$\phi(x, y, z) = \left(\frac{2r^2x}{x^2 + y^2 + (r - z)^2}, \frac{2r^2y}{x^2 + y^2 + (r - z)^2}, 0\right),$$

but since $x^2 + y^2 + (r - z)^2 = 2r^2 - 2rz$, we may simplify this formulation to

$$\phi(x, y, z) = \left(\frac{rx}{r - z}, \frac{ry}{r - z}, 0\right). \tag{13.13}$$

Images

We will find the image of circles on the surface of the sphere under the stereographic projection given by Equation 13.13. We want to do this for two reasons. First, the great circles of a sphere are considered to be the lines in the geometry found on its surface (page 415), so we would like to know their images. Second, we want to show that the sphere is locally Euclidean.

■ THEOREM 13.3.2

The stereographic projection maps a circle on the surface of the sphere onto

- a circle in the plane of projection if the circle does not contain the center of projection.
- a line in the plane of projection if the circle contains the center of projection.

PROOF

Circles on the sphere can be identified by slicing the surface with a plane. We will take the resulting circle, find its image in the plane of projection, and examine the equation that describes the image. Let

$$ax + by + cz = d$$

be a plane that intersects the sphere forming a circle and assume that (x, y, z) is on the surface of the sphere. Using the transformation Equations 13.10, 13.11, and 13.12, we conclude that d equals

$$a\left(\frac{2r^2u}{u^2 + v^2 + r^2}\right) + b\left(\frac{2r^2v}{u^2 + v^2 + r^2}\right) + c\left(\frac{r(u^2 + v^2 + r^2) - 2r^3}{u^2 + v^2 + r^2}\right).$$

Factoring out some common terms yields

$$(2r^2)(au + bv - cr) + cr(u^2 + v^2 + r^2) = d(u^2 + v^2 + r^2),$$

and from here we put the equation into the form of a general conic section with indeterminants u and v as

$$(cr - d)(u^2 + v^2) + (2r^2)(au + bv) - dr^2 - cr^3 = 0. \qquad (13.14)$$

If $cr - d \neq 0$, the coefficients on the two square terms are equal, and this conic is a circle. Its center and radius are found in Exercise 1. If $cr - d = 0$, then $(0, 0, r)$ is on the circle. In this case $(cr - d)(u^2 + v^2)$ drops out, and we are left with the equation for a line. ■

The function ϕ is a one-to-one correspondence because it has an inverse (Equations 13.10, 13.11, and 13.12). It is continuous because $f(x, z) = rx/(r - z)$ is continuous for $r \neq 0$. Since ϕ sends open disks to open disks as a result of Theorem 13.3.2, and since the set of open disks on the sphere serves as a base for its standard topology, ϕ is an open map (Theorem 13.2.6). We may then conclude the next two corollaries.

■ **COROLLARY 13.3.3**

The sphere without a point is homeomorphic to $\mathbb{R}^2$.

■ **COROLLARY 13.3.4**

The sphere is locally Euclidean.

Conformal Functions

A function that preserves angle measure is called **conformal**. We now show that the stereographic projection is a conformal map. What this means for the stereographic projection takes some explanation. Take, for instance, the planes Λ and K, and let them intersect the sphere in two great circles (Figure 13.6). To simplify our diagram, assume that the great circle that contains points A and B lies in the plane of projection K, so that it is projected onto itself. The great circle that contains C and D in Λ intersects the first great circle in B and E and is projected onto K, making the circle that contains C', D', F', and G'. The two projected circles meet in points B and E. We have two choices for the angle between the two great circles. We may choose

$$\theta = \mathrm{m}\sphericalangle ABC = \mathrm{m}\sphericalangle A_1B_1C_1$$

or its supplement ψ. Since both θ and ψ can be used to measure the the angle between planes Λ and K, they also measure the angle formed by the normal vectors of these two planes.

With this setup we can now examine the angles formed by the projected circles. Looking down from above N (Figure 13.7) we see two circles meeting in points B and E. Their centers are O and Q. We have two good options on how to measure the angle at B.

- Use $\sphericalangle OBQ$. This is equivalent to finding the angle between the vector normal to $\odot O$ at B and the vector normal to $\odot Q$ at B.

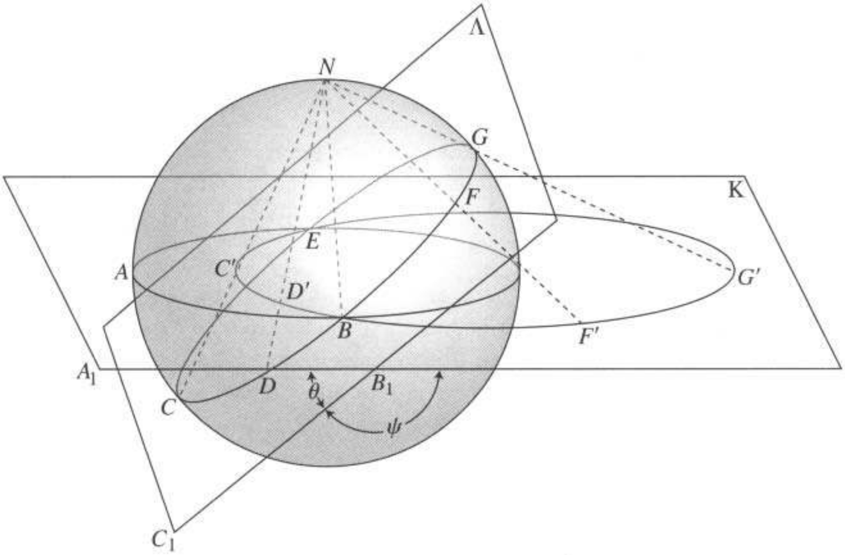

Figure 13.6 The stereographic projection of great circles onto the plane.

- Use $\measuredangle PBR$. This is the angle formed by the tangent to $\odot O$ at B and the tangent to $\odot Q$ at B. This angle is the supplement to $\measuredangle OBQ$ (Exercise 6).

The next theorem shows that $\theta = \text{m}\measuredangle OBQ$ and $\psi = \text{m}\measuredangle PBR$.

■ THEOREM 13.3.5

The stereographic projection maps angles between great circles on the surface of the sphere onto angles of equal measure in the plane of projection.

PROOF

To simplify our calculations, we will assume that the sphere has radius $r = 1$ and neither circle contains N. Take two planes that contain the center of the sphere in Figure 13.6. Assuming that the center also serves as the origin of a coordinate system, let the equations of the planes be

$$ax + by + cz = 0$$

and

$$dx + ey + fz = 0$$

and suppose that

$$a^2 + b^2 + c^2 = 1 \text{ and } d^2 + e^2 + f^2 = 1. \tag{13.15}$$

By Equations 13.15 these planes cut two great circles that form an angle of measure

$$\theta = \cos^{-1}(ad + be + cf).$$

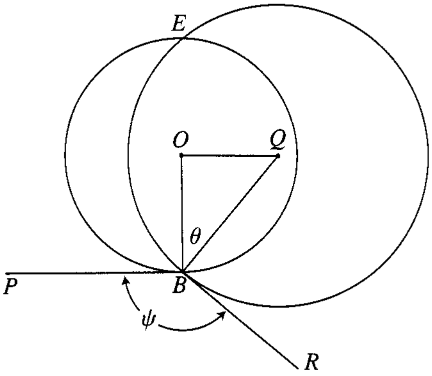

Figure 13.7 The top view of the images in the plane of two great circles.

By Equation 13.14 the projection of the two great circles onto the plane are the circles $\odot O$ and $\odot Q$ with

$$cu^2 + cv^2 + 2au + 2bv - c = 0 \tag{13.16}$$

and

$$fu^2 + fv^2 + 2du + 2ev - f = 0 \tag{13.17}$$

as their equations. Again due to Equations 13.15, we can complete the square on both of these last two equations to find

$$\left(u + \frac{a}{c}\right)^2 + \left(v + \frac{b}{c}\right)^2 = \frac{1}{c^2}$$

and

$$\left(u + \frac{d}{f}\right)^2 + \left(v + \frac{e}{f}\right)^2 = \frac{1}{f^2}.$$

Therefore, $OB = 1/c$ and $QB = 1/f$. We will obtain $\mathrm{m}\measuredangle OBQ$ by using the law of cosines. We first need to compute the distance between the two centers of the circles. It is

$$OQ = \sqrt{\left(\frac{a}{c} - \frac{d}{f}\right)^2 + \left(\frac{b}{c} - \frac{e}{f}\right)^2}.$$

By the law of cosines,

$$\left(\frac{a}{c} - \frac{d}{f}\right)^2 + \left(\frac{b}{c} - \frac{e}{f}\right)^2 = \frac{1}{c^2} + \frac{1}{f^2} - \frac{2\cos B}{cf}.$$

Square the binomials to find that

$$\frac{a^2}{c^2} - \frac{2ad}{cf} + \frac{d^2}{f^2} + \frac{b^2}{c^2} - \frac{2be}{cf} + \frac{e^2}{f^2} = \frac{1}{c^2} + \frac{1}{f^2} - \frac{2\cos B}{cf}.$$

When we gather terms on the left we see that

$$-\frac{2ad}{cf} - \frac{2be}{cf} + \frac{a^2 + b^2 - 1}{c^2} + \frac{d^2 + e^2 - 1}{f^2} = -\frac{2\cos B}{cf}.$$

Because of Equations 13.15, we obtain

$$-\frac{2ad}{cf} - \frac{2be}{cf} - 2 = \frac{-2\cos B}{cf},$$

which finally yields

$$ad + be + cf = \cos B.$$

Therefore, $m\sphericalangle OBQ = \theta$, and since $\sphericalangle OBQ$ and $\sphericalangle PBR$ are supplements, $m\sphericalangle PBR = \psi$. ■

Exercises

1. Find the center and radius of the circle given in Equation 13.14.

2. Suppose that the sphere in Figure 13.5 has unit radius. Find equations for the images of the given circles under ϕ.
   (a) $\{(x, 0, z) : x^2 + z^2 = 1\}$
   (b) $\{(x, y, 0) : x^2 + y^2 = 1\}$
   (c) $\{(x, y, 1/2) : x^2 + y^2 = 3/4\}$
   (d) $\{(x, y, -1/2) : x^2 + y^2 = 3/4\}$
   (e) The circle through $(2/3, 2/3, 1/3)$, $(-2/3, 2/3, 1/3)$, and $(0, \sqrt{3}/2, 1/2)$
   (f) The intersection of the plane $x + y + z = 0$ and the sphere

3. The points $A(2/3, 2/3, 1/3)$, $B(-2/3, 2/3, 1/3)$, and $C(0, \sqrt{3}/2, 1/2)$ also describe an angle on the surface of the unit sphere centered at the origin. Let A be the vertex of this angle.
   (a) Find the equations for the planes whose intersections with the unit sphere are the great circles that contain $\overset{\frown}{AB}$ and $\overset{\frown}{AC}$.
   (b) Find the lengths of $\overset{\frown}{AB}$ and $\overset{\frown}{AC}$.
   (c) Find the measure of spherical $\sphericalangle BAC$.
   (d) Find measure of the angle in $\mathbb{R}^2$ formed by $\phi[\overset{\frown}{AB}]$ and $\phi[\overset{\frown}{AC}]$.

4. What on the surface of the sphere projects onto the y-axis under the stereographic projection? What projects onto the circle $x^2 + y^2 = 4$?

5. What is the image of the upper hemisphere under ϕ, and what is the image of the front hemisphere?

6. Show that $\sphericalangle OBQ$ and $\sphericalangle PBR$ in Figure 13.7 are supplementary.

7. Find the angle formed by the circles $x^2 + y^2 - 2y = 0$ and $x^2 + y^2 - 2y - 5 = 0$.

8. Define ϕ' to be the stereographic projection of a sphere onto a plane that is tangent to the sphere at its south pole. Find parametric equations that describe ϕ'.

9. Reprove Theorem 13.3.5 assuming that at least one of the great circles contains N.

13.4 CONSISTENCY OF NON-EUCLIDEAN GEOMETRY

During the last five years of Gauss's life, his health deteriorated due to severe heart problems, yet there were periods when he fought his illness successfully and showed increased stamina. One such time was upon publication of Riemann's *Habilitationsschrift*. Although he expressed excitement about the results, his failing memory and trouble concentrating left him unable and unwilling for deep mathematical conversation. When able, he did involve himself with some simple problems, but he seems to have preferred reading newspapers and other popular literature. During this time, Gauss expressed a belief in God. He was not a Christian but would be better described as a deist who believed in an afterlife. He thought that when one died, one would perceive more clearly the geometric nature of the universe. Gauss evidently hoped that it would be non-Euclidean, since he liked the concept of an absolute measure of length. On February 23, 1855, Gauss died in his home. It is said that his watch stopped moments after his death (Bühler 1981, 152–155).

Two years later, in 1857, Riemann joined the regular faculty at Göttingen, and after another two years he was promoted to the chair of mathematics that had been held by Gauss. Unfortunately, Riemann had contacted tuberculosis. His doctor recommended a warmer climate, so he moved to Italy. He died there near Lake Maggiore on July 20, 1866 at the age of 39. Dying at such a young age, Riemann did not live to see what just a few years later would follow from his work (Gray 2007, 189; Bühler 1981, 152–155; Burton 1985, 564).

Beltrami Models

Lobachevski wrote his geometry using algebra, trigonometry, and calculus, so he believed that his new system was without contradiction. However, he did not provide a proof. The first to put the new geometry on a sound logical footing was Eugenio Beltrami. He was born in Cremona, Italy on November 16, 1835. Many of his relatives were talented in various forms of art, including the engraving of cameos and the painting of miniatures. Beltrami himself enjoyed music and would eventually study its relationship to mathematics. Beltrami was a student from 1853 to 1856 at the University of Pavia, but financial problems would take him away from his academic life to work as a secretary for the railroad in Verona. His new occupation would later take him to Milan, where in his free time he resumed his mathematical pursuits. His early interests were greatly influenced by both Gauss and Riemann and included differential geometry. Beltrami gained a solid reputation for mathematics and would eventually hold various positions in algebra, geometry, and mechanics at universities throughout Italy, including Bologna, Pisa, and Rome. No biography of Beltrami is complete, even one as short as this, without mentioning that it was he who was responsible for rediscovering Saccheri's *Euclides Vindicatus* (Struik 1970a, 599-600; Gray 2006, 79; Stillwell 1996, 3).

Building on Riemann's work, Beltrami was the first to prove that the Parallel Postulate was not provable. He did this by allowing the terms *point* and *line* to be reinterpreted, such as when great circles are considered to be the lines on a sphere. Any example that satisfies the postulates under the new interpretation will be called a **model** of the postulates. If we find such a model, we conclude that the postulates are consistent (page 324). Finding a model yields consistency because we believe that neither mathematics nor the physical world are self-contradictory, so any set of statements interpreted within either of these contexts could not lead to a contradiction.

Beltrami's first consistency proof is found in his "Essay on the Interpretation of Noneuclidean Geometry" (*Saggio di Interpretazione della Geometria Non-euclidea*). In this paper, Beltrami modeled the new geometry using geodesics on a surface of constant negative curvature. The notion of curvature was developed by Gauss in his *Disquisitiones Circa Superficies Curvas* of 1827. It is an intrinsic property of a surface and is measured with real numbers. Spheres have constant positive curvature, while planes and cylinders are considered flat, having zero curvature. The advantage of having any kind of constant curvature is that shapes can be moved on the surface without deforming. An example of a surface with constant negative curvature was studied by Gauss's student Ferdinand Minding in 1840. All of the trigonometric formulas of Lobachevski and Bolyai held true on this surface, so it was a logical candidate for interpreting non-Euclidean geometry (Stillwell 1996, 1–2; Boyer and Merzbach 1991, 505–506).

Minding's surface is brought about by revolving a particular curve about the y-axis. Attach a rope to a relatively heavy object sitting on the ground. While holding the rope, walk away from it until the rope is taught. Now start to pull the object by turning right and walking along the straight line that is perpendicular to the rope. As you do this, the object will be dragged along a path known as a **tractrix** (Figure 13.8). This curve was originally described by Leibnitz. Some have used the German word *hundkurve* to describe it because we can imagine the curve representing the path that a dog would take as it goes on a walk with a leash (Steinhaus 1999, 250–251).

To derive the equation for the tractrix, place the object along the x-axis at $x = a$. Let O be the origin and P an arbitrary point along the curve. Let T represent the point of intersection between the y-axis and the tangent to the tractrix at P. As the object is pulled (or the dog led), the rope is represented by that tangent, so $PT = a$. If the coordinates of P are (x, y) and $x \leqslant a$, then

$$OT = y + \sqrt{a^2 - x^2}$$

and

$$\frac{dy}{dx} = -\frac{\sqrt{a^2 - x^2}}{x}.$$

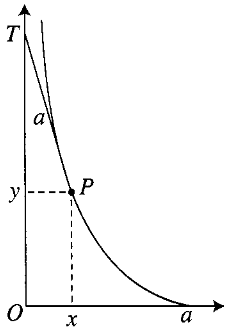

Figure 13.8 The tractrix.

To solve this differential equation we write

$$\int dy = -\int \frac{\sqrt{a^2 - x^2}}{x}\, dx.$$

Focusing our work on the right-hand side of the equation, we substitute $x = a \sin\theta$:

$$\int \frac{\sqrt{a^2 - x^2}}{x}\, dx = a \int \frac{\cos^2\theta}{\sin\theta}\, d\theta = a \int (\csc\theta - \sin\theta)\, d\theta.$$

Because

$$\int (\csc\theta - \sin\theta)\, d\theta = -\ln\left|\frac{a}{x} + \frac{\sqrt{a^2 - x^2}}{x}\right| + \frac{\sqrt{a^2 - x^2}}{a} + C$$

and $y = 0$ when $x = a$, we conclude that

$$y = a \ln\left(\frac{a + \sqrt{a^2 - x^2}}{x}\right) - \sqrt{a^2 - x^2}. \tag{13.18}$$

The original derivation of the equation for the tractrix is due to James Bernoulli (Kline 1972, 473–474).

Now take the tractrix and rotate it about its asymptote. The result is a solid called a **pseudosphere** (Figure 13.9). This surface is the simplest that has constant negative curvature. However, since the pseudosphere has a single point at infinity, it cannot represent the entire Lobachevskian plane. Instead, it models a portion that is bounded by two parallel lines and an arc of a horocycle. The surface that Beltrami used to show the consistency of **HA** was essentially a covering that wrapped around the pseudosphere infinitely many times. With minor modification this can be made to represent an arbitrarily large portion of the non-Euclidean plane (Stillwell 1996, 2; Sommerville 1958, 169–170).

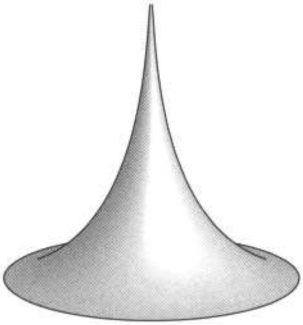

Figure 13.9 The pseudosphere.

In another of his papers, entitled "Fundamental Theory of Spaces of Constant Curvature" (*Teoria fondamentale degli spazii di curvatura constante*), Beltrami generalized his results to n dimensions. He also gave early versions of models that are now named after Henri Poincaré and Felix Klein and one that we will call Beltrami's **hemisphere model** (Figure 13.10). Take the hemisphere in $\mathbb{R}^3$ given by the equation

$$x^2 + y^2 + z^2 = r^2$$

and let $z > 0$. The surface of the hemisphere is interpreted to be the plane, *points* are regular points on the surface, and *lines* are the geodesics formed by slicing the model with vertical planes. The great circle $z = 0$ represents the line ω at infinity. To find the parallel lines of this model, let l be an arc formed by cutting the hemisphere with perpendicular plane Λ and let P be a point on the surface but not on l. Turn Λ until it intersects P by using the perpendicular to one of the endpoints of l as an axis. The resulting arc contains P and intersects l at a point on ω. This arc is considered parallel to l. If Λ had been turned using the other endpoint of l, the result would be the other parallel to l through P (Stillwell 1996, 35–37).

Both of Beltrami's models show that the geometries of Lobachevski and Bolyai are consistent by transferring the question to one within Euclidean geometry. If

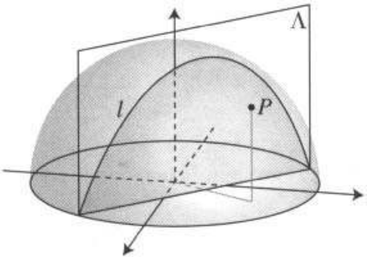

Figure 13.10 The hemisphere model.

there is an interpretation of non-Euclidean geometry that satisfies the negation of the Parallel Postulate, then non-Euclidean geometry is without contradiction if the system in which it is being interpreted has no contradictions. Since mathematicians were confident in the consistency of Euclid's system, they should now have confidence in the new geometry. This concept is known as **relative consistency**. All consistency proofs are actually proofs of relative consistency.

Poincaré Models

There are two models associated with Poincaré that can be obtained from Beltrami's hemisphere model. Obtain the first by stereographically projecting the hemisphere onto the plane $z = 0$ by completing the bottom half of the sphere and using the south pole as the center of projection (Definition 13.3.1). Let $\mathscr{C}$ be the circle with equation

$$x^2 + y^2 = r^2.$$

The images of points from the hemisphere lie within $\mathscr{C}$ and are the *points* of the model. The images of the arcs of the hemisphere will be projected onto either segments within $\mathscr{C}$ or half-circles within $\mathscr{C}$ that intersect the circle at right angles (Theorem 13.3.2). These are the *lines* of the model. Two lines are said to be parallel in this model if they intersect at $\mathscr{C}$. This means that $\mathscr{C}$ is interpreted as the line at infinity. The image of the hemisphere within the circle $\mathscr{C}$ is called the **Poincaré disk model** (Figure 13.11). Poincaré published this model in 1882 (Stillwell 1996, 35–36).

The second model is known as the **Poincaré half-plane model**. Take a plane Λ that is tangent to the Beltrami hemisphere at Q but perpendicular to the plane $z = 0$ (Figure 13.12). Let P be on the hemisphere opposite Q so that $\overline{PQ}$ is perpendicular to Λ. The image on the upper half of Λ of the hemisphere under the stereographic projection with center P is Poincaré's model. Points and lines are interpreted as in the Poincaré disk, and the intersection of Λ and $z = 0$ is the line at infinity (Stillwell 1996, 36–37).

The mathematician responsible for these two models earned a reputation that approached that of Gauss. Poincaré was born in Nancy, France on April 29, 1854.

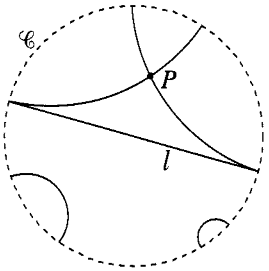

Figure 13.11 The Poincaré disk.

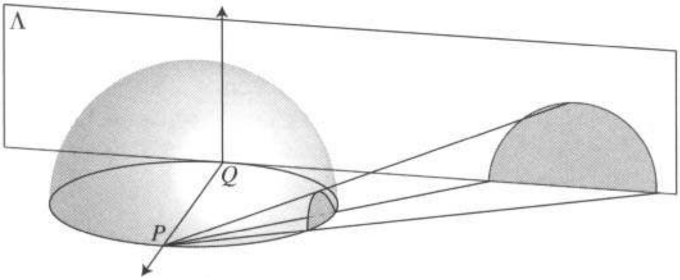

Figure 13.12 Stereographic projection of the hemisphere onto the Poincaré half-plane.

He was from an upper-middle-class family, and his relatives included physicians, professors, and politicians. He attended the École Polytechnique, and after graduating Poincaré worked at engineering while he studied for his doctorate degree in mathematics. He finished in 1879. Afterward he taught at the University of Caen and became a professor at the University of Paris in 1881. At the young age of 33, he was elected to the Académie des Sciences. He had wide mathematical interests that included function theory, number theory, algebra, and the foundations of mathematics. In addition to mathematics, Poincaré made important contributions to astronomy and physics (Dieudonné 1970, 51–61).

Klein Models

Felix Klein was another leading nineteenth century mathematician. He was born in Düsseldorf on April 25, 1849. His father worked in the government finance office and had very traditional Prussian views. This resulted in Klein attending the gymnasium in his hometown where he studied classical languages but very little mathematics. After graduation he attended the University of Bonn in 1866, where he met Julius Plücker. Klein was soon recruited by Plücker and became his assistant with the goal being to make Klein into a physicist. Klein had the talent for it, and it might have happened except that Plücker died in 1868. At the time Plücker had been working on various papers, including one on geometry. As his assistant, Klein prepared the unfinished works for publication and was particularly inspired by Plücker's *Neue Geometrie des Raumes*. By the end of the year, Klein finished his doctorate degree, moved to Göttingen for a few months, and then moved on to Berlin. This was followed by a trip to Paris that was interrupted by the Franco-Prussian War, and then a return to Göttingen, where he taught mathematics as a lecturer in 1871 (Yaglom 1988, 25–27; Burau and Schoenberg 1970, 396).

It was during this year that Klein's "On the So-called Noneuclidean Geometry" was published. It included a model of the geometry of Lobachevski and Bolyai. If Beltrami's hemisphere model is orthogonally projected onto the plane, the result is an open disk with the geodesics of the hemisphere mapped to chords of the circle. Viewing the plane as a copy of $\mathbb{R}^2$, the equation for the disk is $x^2 + y^2 < r^2$, where r

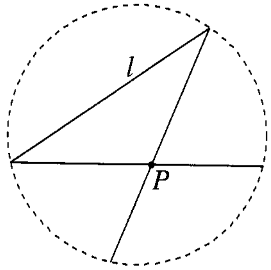

Figure 13.13 The Klein disk.

is the radius of the hemisphere. This is called the **Klein disk model** (Figure 13.13). The *points* of the model are regular points, and the *lines* are chords of the circle without the endpoints. Two lines are parallel if they meet at a point on the circle, and they are nonintersecting if the do not meet anywhere within or on the circle.

Klein also provided models that showed that the Hypothesis of the Obtuse Angle was possibly true. His motivation for this can be traced to Riemann. From Saccheri to Lobachevski and Bolyai, geometers did not accept geometries in which **HO** held. In such systems, Theorem 5.3.9 was false. Since this proposition was part of their data from Euclid that was not based on the Parallel Postulate, they consistently rejected **HO** as a possibility. This is surprising since it was a known fact that the angle sum of a triangle on the surface of a sphere had angle sum greater than two right angles. It was left to Riemann to accept that this surface yielded its own geometric system (Bonola 1912, 141).

Riemann observed that there are essentially three types of two-dimensional geometries, based on the type of surface on which it lies:

- A flat surface such as a plane or cylinder
- A surface of constant negative curvature such as a pseudosphere
- A surface of constant positive curvature

The first of these is Euclidean geometry and the second is Lobachevski's. The third can be interpreted as existing on the surface of a sphere, but to do this we must rethink our understanding of lines. According to Riemann:

> In the extension of space-construction to the infinitely great, we must distinguish between *unboundedness* and *infinite extent*; the former belongs to the extent relations, the latter to the measure-relations. That space is an unbounded threefold manifoldness, is an assumption which is developed by every conception of the outer world; according to which every instant the region of real perception is completed and the possible positions of a sought object are constructed, and which by these applications is forever confirming itself. The unboundedness of space possesses in this way a greater empirical certainty than any external experience. But its infinite extent by no means follows from this; on the other hand if we assume independence of bodies from position, and therefore ascribe

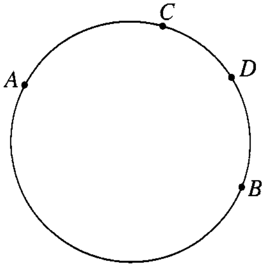

Figure 13.14 A finite, closed line.

> to space constant curvature, it must necessarily be finite provided this curvature has ever so small a positive value. If we prolong all the geodesics starting in a given surface-element, we should obtain an unbounded surface of constant curvature, *i.e.*, a surface which in a *flat* manifoldness of three dimensions would take the form of a sphere, and consequently be finite. (Riemann 1854, III.2, 67–68)

The result of Riemann's comments is two definitions that had previously not been applied to lines. We say that a line is **finite** if its length is finite. A line l is **closed** if given any two points A and B on l, there exist points C and D on l such that C and D are between A and B but B is between C and D (Figure 13.14).

This change requires a change in the postulates of Euclid. Since the days of the Greeks, geometers nearly universally assumed that lines were infinite. Even many of Euclid's proofs assumed this, despite this property not being found among the postulates. Therefore, this new geometry requires that Euclid's first and last postulates be replaced with the following two.

■ POSTULATES 13.4.1 [Riemann]

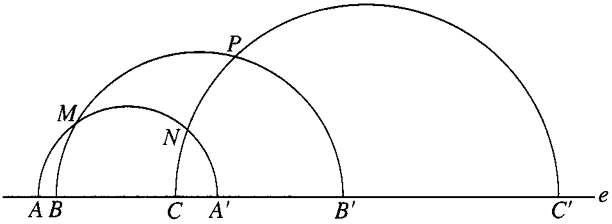
1. All lines are closed and finite.
2. All lines intersect.

In the development of this **Riemannian geometry** we may keep certain of Euclid's theorems up through *Elements* I.28 (Theorem 5.4.1), but others will have to be jettisoned. This includes the previously mentioned Theorem 5.3.9. We also cannot keep Theorem 5.3.12. The proofs of both of these propositions relied on lines being infinite, as indicated in Exercise 8.

Since the next theorem implies the existence of a triangle that has an angle sum greater than two right angles, we conclude by Theorem 10.3.1 that **HO** holds in this geometry.

■ THEOREM 13.4.2 [Riemann]

All lines perpendicular to a given line are concurrent.



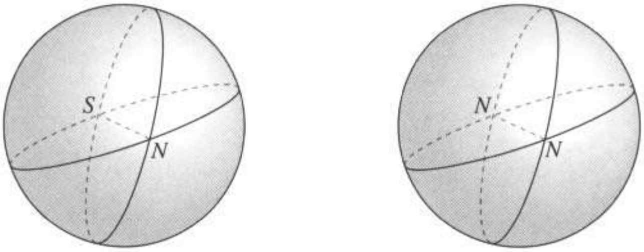
PROOF

Let e be a line and A a point on e. Let A' be chosen so that $\overline{AA'}$ is perpendicular to e. Since $\overline{AA'}$ is closed, it must intersect e again. The second time $\overline{AA'}$ intersects e is either back at A by looping back or by intersecting in some new point. Suppose it is the latter and that this new point is A'. Draw two more lines perpendicular to e at B and C and let the respective lines intersect e for a second time at B' and C'. By Postulate 13.4.1.2, the three pairs of lines intersect. Let M be the intersection of $\overline{AA'}$ and $\overline{BB'}$, N the intersection of $\overline{AA'}$ and $\overline{CC'}$, and P the intersection of $\overline{BB'}$ and $\overline{CC'}$. Since $\sphericalangle MAB$ and $\sphericalangle MBA$ are both right, $\triangle ABM$ is an isosceles triangle. Hence, $\overline{AM} \cong \overline{BM}$. Similarly, $\triangle BA'M$ is isosceles, so we conclude that $\overline{BM} \cong \overline{MA'}$. Thus, M is the midpoint of $\overline{AA'}$. A similar argument will show that N is also the midpoint of $\overline{AA'}$, from which we conclude that $M = N$. Since M and P are midpoints of $\overline{BB'}$, we see that they are in fact the same point. Hence, the three lines are concurrent. ■

The point N that exists on one side of the line e in the proof of Theorem 13.4.2 on which all perpendiculars to the line fall is called the **absolute pole** of e. The line e is the **absolute polar** of N. For any point P on e, $\overline{NP}$ is called a **quadrant**, and we say that N is **orthogonal** to P. All quadrants on the same side of e are congruent (Exercise 14).

Certainly on the other side of e we may repeat the construction above and find a point S that is contained by all perpendiculars. The question now is whether the points N and S are different. It turns out that both options are consistent with the postulates for this geometry. If N and S are different, the points are called **antipodal** and the geometry is called **double elliptic**. If this is the case, lines meet in two points, so Euclid's first postulate cannot hold. If, instead, the points are the same, we regain Euclid's assumption that two points determine a line. This geometry is called **single elliptic**. This terminology is due to Klein but from a different context. It has now become common to use the terms **elliptic** for geometries that satisfy **HO** and **hyperbolic** for the geometry of Lobachevski and Bolyai (Bonola 1912, 164; Wussing 1984, 177).

The two elliptic geometries were proven consistent by models given by Klein (Burton 1985, 568). He realized them on the surface of a sphere. Double elliptic is illustrated in Figure 13.15(a). *Lines* in the model are great circles of the sphere, and *points* are regular points on its surface. There is no line at infinity because there are no parallels. This model satisfies Postulates 13.4.1 and the three remaining postulates of Euclid.



(a) Double elliptic (b) Single elliptic

Figure 13.15 Klein's models of elliptic geometry.

Single elliptic geometry is modeled in Figure 13.15(b). Here, *lines* are as in double elliptic; however, *point* is understood to refer to pairs of antipodal points on the surface of the sphere. Postulates 13.4.1 hold true in this model as well as all of Euclid's postulates except for the last postulate concerning parallels.

Exercises

1. Locate the point at infinity for the pseudosphere. Use this point to identify which objects on the surface of the pseudosphere should represent lines, parallel lines, and nonintersecting lines.

2. Assume $a = 1$ in the equation for the tractrix (Equation 13.18). This makes the equation equivalent to $y = \operatorname{sech}^{-1}x - \sqrt{1 - x^2}$.
   - (a) Confirm this result.
   - (b) Show that the surface area of the pseudosphere (the surface area of revolution of the tractrix) can be approximated by 12.56. What is the significance of this result?
   - (c) Show that the volume of the pseudosphere can be approximated by 2.09. What is the significance of this result?

3. A **pseudosquare** is a quadrilateral that is equilateral and equiangular. How can a pseudosquare be constructed in hyperbolic geometry?

4. Draw a picture representing parallel lines in Beltrami's hemisphere model.

5. Create a diagram for each of the Poincaré models and the Klein model that includes examples of points, lines, parallel lines, nonintersecting lines, and triangles.

6. The Poincaré models and the Klein model are intended to represent the non-Euclidean plane of Lobachevski and Bolyai. If this is the case, what is missing from the descriptions of these models in the section?

7. Draw horocycles in the Poincaré and Kline models.

8. Show that Theorems 5.3.9 and 5.3.12 are false under **HO**.

9. Let the open square $(0, 1) \times (0, 1)$ be the plane, *points* be regular points, and *lines* be line segments with endpoints on the border of the square. Is this geometry Euclidean? What is the angle sum of triangles? How do you harmonize the answers to these questions?

10. Prove that rectangles do not exist in elliptic geometry.

11. Explain why in single elliptic geometry a line does not separate the plane into two half planes. With this in mind, give an example of a "flat" model of double elliptic geometry.

12. Do lines divide the plane into two half planes in double elliptic geometry? Explain.

13. Does Pasch's Postulate (11.3.2) hold in either of the elliptic geometries?

14. Prove that all quadrants on the same side of e are congruent in Riemann's elliptic geometry.

15. What is the maximum measure of the third angle of a triangle with two right angles?

CHAPTER 14

JEAN-VICTOR PONCELET

Gaspard Monge was a significant figure in late eighteenth century French mathematics. In 1775, at the age of 29, he was appointed the Royal Professor of Mathematics and Physics at the École Militaire de Méziers. There he developed a method of designing forts that effectively defended the soldiers within from gunfire that originated from multiple directions. This led to Monge's creation of a field of mathematics known as **descriptive geometry**. Monge left Méziers in 1784 to become the head of naval education in France, and 10 years later he was appointed to another influential education position, one that led to the creation of École Polytechnique in June 1795. This was a two-year school designed to prepare students for the study of engineering. Its curriculum, which included both descriptive and differential geometry, was designed by mathematicians who believed that a study of pure mathematics was the best way to prepare their students for the various options they would have in their future studies. Besides his duties at École Polytechnique, Monge remained professionally active outside of the school. This included working to revive the French professional organizations, which had been neglected after the revolution, and accompanying Napoleon to Egypt, where he led the scientific team. When Monge returned a year later, he continued teaching at École Polytechnique until 1809. During his tenure there, Monge was a champion of synthetic geometry, and he conveyed this passion to

Revolutions of Geometry. By Michael O'Leary
Copyright © 2010 John Wiley & Sons, Inc.

one of his students: Jean-Victor Poncelet (Gray 2007, 4–6, 7; Gray 2004, 30; Boyer and Merzbach 1991, 468, 478).

The son of wealthy and politically influential parents, Poncelet was born on July 1, 1788 in the French town of Metz, a city that remained dear to him his entire life. At a very early age, Poncelet was sent away for his preliminary schooling and then returned to his family in 1804. Three years later he enrolled at École Polytechnique but fell behind due to poor health and took an extra year to complete his studies. After completing his work at École Polytechnique, Poncelet joined the corps of engineers in September 1810. A year and a half later he was assigned to the Dutch island of Walcheren, and in June 1812 he took part in the French invasion of Russia. Despite his role as an engineer and not as a fighting soldier, Poncelet was taken prisoner on November 18, 1812 during the retreat. He was held as a prisoner of war at Saratov and not released until June 1814. While in Russia, Poncelet spent his time writing. The result was a text on analytic geometry based on his studies at École Polytechnique. He would eventually have it published but not for 50 years. It was intended to be an introduction to his second work, the *Traité des propriétés projectives des figures*. This work would be published in 1822. Begun during the days of his imprisonment, in the *Traité* Poncelet aimed to write a geometry treatise using synthetic methods, yet with the generality of analytic geometry (Taton 1970, 76; Boyer and Merzbach 1991, 535).

The methods Poncelet used in the *Traité* were projective. For example, he used ideal points and introduced a new concept called **imaginary points**. These were defined in such a way that any line and circle would always intersect at one of these points (Boyer and Merzbach 1991, 535). Unfortunately, Poncelet had little familiarity with the work of Desargues and Pascal. The *Brouillon Project* of Desargues was lost soon after he wrote it, and it remained lost until 1847, when the handwritten copy made by Philippe de Lahire was discovered in a Paris library. This was 33 years after Poncelet's time in Russia. The result was that Poncelet spent unnecessary time reproving many of the early projective theorems. Nonetheless, Poncelet made further advancements in the subject, including developments regarding involutions and conic sections (Kline 1972, 840, 842; Boyer and Merzbach 1991, 361).

Poncelet viewed his projective geometry as a new branch of mathematics with its own distinct methods. One example of this is Poncelet's **principle of continuity**. Let us illustrate how it works by considering two theorems regarding secants and tangents to a circle. Let A and D be on a circle and C outside the circle such that they form secants $\overline{AC}$ and $\overline{DC}$ that intersect the circle in points B and D', as in Figure 14.1. We know by the Secant Theorem (5.5.4) that

$$AC \cdot BC = DC \cdot D'C.$$

Now let D move along the circumference of the circle so that it approaches D'. As this happens, the secant $\overline{DC}$ will eventually intersect the circle in only one point, so that it becomes a tangent, and this happens when D and D' coincide. Therefore, the equation obtained from the Secant Theorem becomes

$$AC \cdot BC = DC^2,$$

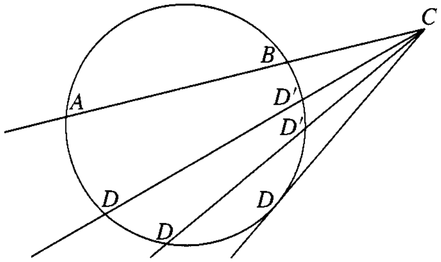


Figure 14.1 The Tangent-Secant Theorem and the principle of continuity.

which is what follows from the Tangent-Secant Theorem (Theorem 5.5.5). Poncelet's strategy is familiar to us. We have seen such continuity arguments used at various times. However, during the nineteenth century mathematicians were becoming more aware of the unstated assumptions that they had been using in the past. A champion of these new standards was Cauchy. He is known for his foundational work on the definitions of limit and continuity in calculus. He believed that it was important that these ideas have a rigorous foundation and was highly critical of Poncelet's principle (Burton 1985, 535; Kline 1972, 843, 950–953).

Poncelet took Cauchy's criticisms personally. He did not consider his principle of continuity a less rigorous form of mathematics. Quite the contrary, Poncelet viewed his principle as a postulate that allowed him to argue as he did. He rejected the notion that his projective geometry needed the analytic foundations that Cauchy apparently desired. Despite Cauchy's formidable reputation as one of the leading mathematicians of the time, Poncelet held his ground and set out to expand and clarify his geometric innovations. The result was an additional opening section to the *Traité*. This addition would make the *Traité* the major work of nineteenth-century projective geometry (Taton 1970, 77).

Partly due to the issues he had with Cauchy, and partly due to other controversies with which he found himself embroiled, Poncelet would eventually all but abandon geometry in favor of applied mechanics. In 1824 he became professor at École d'Application de l'Artillerie et du Génie at Metz. His appreciation of both the theoretical aspect of mechanics and its experimental side made him an excellent teacher. Eventually, the course on machine mechanics that he developed became very popular and widely used at other institutions. Poncelet's interest in machinery was not limited to the classroom, however. His fascination with mechanical devices led to his 1825 tour of France, Belgium, and Germany to visit various factories and study their machinery. Also in that year, Poncelet won a prize from the Académie des Sciences for his design of a more efficient undershot waterwheel. Its secret was in its curved paddles (Taton 1970, 77, 78).

As with many with a military background, Poncelet acquired an interest in politics. In 1830 he became a member of the city council of Metz. Seemingly destined to live the rest of his life in his hometown, plans changed in 1834, when Poncelet accepted an appointment to the school of mechanics at the Académie des Sciences in Paris. There he continued teaching, and later, in 1837, he created a course for the Faculty of Sciences of Paris. He married in 1842, and at this point he was no longer doing original research. He was happy to spend his time teaching and continuing his technical investigations. This all changed with the revolution of 1848. Poncelet was appointed brigadier general and assigned to be the commandant of École Polytechnique. While there, Poncelet was seemingly involved in every aspect of the institution: from reforming the school's curriculum to maintaining student order during the riots of mid-1848 (Taton 1970, 78–79).

Poncelet retired in 1850 and decided to edit and publish his collected works. He completed only four volumes. Two volumes were a second edition of the *Traité des propriétés projectives des figures*, and the other two were titled *Applications d'analyse et de géométrie*. This was the work on analytic geometry that he had written while a prisoner in Russia. Before he could complete the volumes on mechanics, Poncelet died in Paris, on December 22, 1867 (Taton 1970, 76, 78–79).

14.1 THE PROJECTIVE PLANE

We defined the projective plane in Section 9.2 when we studied Desargues. We defined it by adding points and a line at infinity to a Euclidean plane. The modern viewpoint turns this around and first defines the projective plane and then by removing elements constructs a Euclidean one.

Projective Axioms

The work in this section is based on Bennett (1995, 41–49) and the classic Veblen and Young (1910, 15–20). Let $\mathcal{P}$ and $\mathcal{L}$ be two nonempty sets. The elements of $\mathcal{P}$ will be called **points**, and the elements of $\mathcal{L}$ will be called **lines**. Assume that the points are fundamental and that a line is a set of points. We will use geometric terminology when we write sentences about the points and lines, but these should be interpreted with our new understanding. If we say that a point P **lies on** or is **incident** with a line l, this means that $P \in l$. Similarly, the line l **contains** or is **incident** with a point P if $P \in l$. Two points P and Q in $\mathcal{P}$ are **collinear** if there exists a line in $\mathcal{L}$ that contains both P and Q as elements, and two lines m and l are **concurrent** if there exists a point that is an element of both lines. Both collinear and concurrent can be generalized to any number of points and lines. Finally, if points P and Q chosen from $\mathcal{P}$ are the same, write $P = Q$; otherwise, they are **distinct** and we write $P \neq Q$. The pair $(\mathcal{P}, \mathcal{L})$ is called a **projective plane** when it follows these rules:

■ **POSTULATES 14.1.1**

1. For all distinct $P,\ Q \in \mathcal{P}$, there exists a unique line l in $\mathcal{L}$ such that P and Q are incident with l.

2. For all distinct $l,\ m \in \mathcal{L}$, there is a point incident with both l and m.

3. Every line contains at least three points.

4. There are at least two lines.

The geometric theory that satisfies these postulates is called a **projective geometry**. Notice that the second postulate states that projective geometry is elliptic.

Different authors will choose different sets of postulates. These are from Bennett. Veblen and Young use a different collection, which replaces some of the propositions of Postulates 14.1.1. These will serve as our first theorem, but its proof is left to Exercise 10.

■ THEOREM 14.1.2

Let $(\mathcal{P}, \mathcal{L})$ be a projective plane.

- There exists $P, Q \in \mathcal{P}$ such that $P \neq Q$ and P and Q are not collinear.
- For all $P, Q, R \in \mathcal{P}$, if P, Q, and R are not collinear, there exist points S, T, and U in $\mathcal{P}$ with $P \neq S$ such that P, R, and T are collinear, P, Q, and U are collinear, and S, T, and U are collinear.

Consistency

We now show that the projective geometry described by Postulates 14.1.1 is consistent by finding a model.

■ THEOREM 14.1.3

If $\mathcal{P} = \{0, 1, 2, 3, 4, 5, 6\}$ and $\mathcal{L}$ is the set

$$\{\{0, 1, 3\}, \{1, 2, 4\}, \{2, 3, 5\}, \{3, 4, 6\}, \{4, 5, 0\}, \{5, 6, 1\}, \{6, 0, 2\}\},$$

$(\mathcal{P}, \mathcal{L})$ is a projective plane.

PROOF

To prove this, we must systematically check that the four postulates hold under this definition of $\mathcal{P}$ and $\mathcal{L}$.

1. The table enumerates all possible pairs of distinct points and the unique line to which the pair belongs, so the first postulate is seen to be satisfied.

Points		Line	Points		Line	Points		Line
0	1	{0, 1, 3}	1	3	{0, 1, 3}	2	6	{6, 0, 2}
0	2	{6, 0, 2}	1	4	{1, 2, 4}	3	4	{3, 4, 6}
0	3	{0, 1, 3}	1	5	{5, 6, 1}	3	5	{2, 3, 5}
0	4	{4, 5, 0}	1	6	{5, 6, 1}	3	6	{3, 4, 6}
0	5	{4, 5, 0}	2	3	{2, 3, 5}	4	5	{4, 5, 0}
0	6	{6, 0, 2}	2	4	{1, 2, 4}	4	6	{3, 4, 6}
1	2	{1, 2, 4}	2	5	{2, 3, 5}	5	6	{5, 6, 1}

2. The next table shows that all pairs of distinct lines contain a common point.

Lines		Point	Lines		Point
{0, 1, 3}	{1, 2, 4}	1	{2, 3, 5}	{3, 4, 6}	3
{0, 1, 3}	{2, 3, 5}	3	{2, 3, 5}	{4, 5, 0}	5
{0, 1, 3}	{3, 4, 6}	3	{2, 3, 5}	{5, 6, 1}	5
{0, 1, 3}	{4, 5, 0}	0	{2, 3, 5}	{6, 0, 2}	2
{0, 1, 3}	{5, 6, 1}	1	{3, 4, 6}	{4, 5, 0}	4
{0, 1, 3}	{6, 0, 2}	0	{3, 4, 6}	{5, 6, 1}	6
{1, 2, 4}	{2, 3, 5}	2	{3, 4, 6}	{6, 0, 2}	6
{1, 2, 4}	{3, 4, 6}	4	{4, 5, 0}	{5, 6, 1}	5
{1, 2, 4}	{4, 5, 0}	4	{4, 5, 0}	{6, 0, 2}	0
{1, 2, 4}	{5, 6, 1}	1	{5, 6, 1}	{6, 0, 2}	6
{1, 2, 4}	{6, 0, 2}	2			

3. Every line has at least three points by definition.

4. There are clearly at least two lines. ■

There are **infinite models** of projective geometry. The Euclidean projective plane of Desargues (Section 9.2) is an example. Other models include those for single elliptic geometry and the **Riemann sphere**, the complex numbers joined with a point at infinity. The Riemann sphere is denoted by $\mathbb{C}^*$ or $\mathbb{C} \cup \{\infty\}$.

Isomorphic Models

Although one model is sufficient to show the consistency of a set of postulates, there are many different models for projective geometry. Our first was an example of a **finite model**. Here is another. It is named after Gino Fano (1871–1952). Fano was a respected projective and algebraic geometer who was a professor at the University of Turin until he lost his position under the Fascist laws of 1938. During World War II he taught Italian students at Lausanne, and after the war he continued his research and lecturing in both Italy and the United States (Struik 1970b, 522–523).

■ **THEOREM 14.1.4 [Fano Plane]**

If $\mathscr{P}_F$ is the set of dots illustrated by Figure 14.2 and

$$\mathscr{L}_F = \{\overline{EBA}, \overline{ADG}, \overline{EFG}, \overline{BCG}, \overline{ECD}, \overline{ACF}, \odot BDF\},$$

then $(\mathscr{P}_F, \mathscr{L}_F)$ is a projective plane.

We leave it to Exercise 8 to check that the interpretation satisfies Postulates 14.1.1 and that it is the smallest model to do so.

It should be noted that there is actually little difference between Theorem 14.1.3 and Theorem 14.1.4. The only variation between the two are the names of the elements. To see this, let $\mathscr{P}$ be from Theorem 14.1.3 and define $\phi : \mathscr{P}_F \to \mathscr{P}$ by

$$\phi(A) = 0, \phi(B) = 1, \phi(C) = 2, \phi(D) = 5, \phi(E) = 3, \phi(F) = 6, \text{and } \phi(G) = 4.$$

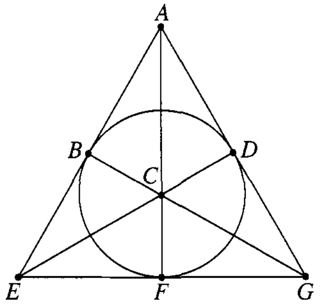

Figure 14.2 The Fano plane.

This function associates pairs of elements in such a way that if three points are on a line in one model, the corresponding points would be on a line in the other model. For instance, $\overline{EBA} = \{E, B, A\}$, $\phi(E) = 3$, $\phi(B) = 1$, and $\phi(A) = 0$. Thus,

$$\phi[\{E, B, A\}] = \{0, 1, 3\},$$

and for the rest of the lines we have

$$\begin{aligned}\phi[\{A, D, G\}] &= \{4, 5, 0\},\\ \phi[\{E, F, G\}] &= \{3, 4, 6\},\\ \phi[\{B, C, G\}] &= \{1, 2, 4\},\\ \phi[\{E, C, D\}] &= \{2, 3, 5\},\\ \phi[\{A, C, F\}] &= \{6, 0, 2\},\\ \phi[\{B, D, F\}] &= \{5, 6, 1\}.\end{aligned}$$

We now generalize this result.

■ DEFINITION 14.1.5

Let $(\mathcal{P}, \mathcal{L})$ and $(\mathcal{P}', \mathcal{L}')$ be projective planes. If $\phi : \mathcal{P} \to \mathcal{P}'$ is a one-to-one correspondence such that for all $P, Q, R \in \mathcal{P}$,

$$R \in \overline{PQ} \text{ if and only if } \phi(R) \in \overline{\phi(P)\phi(Q)},$$

then ϕ is a **collineation**.

If there is a collineation between two projective planes, the planes look identical except for the names put on their elements.

■ DEFINITION 14.1.6

The projective planes $(\mathcal{P}, \mathcal{L})$ and $(\mathcal{P}', \mathcal{L}')$ are **isomorphic** if there exists a collineation $\phi : \mathcal{P} \to \mathcal{P}'$.

Independence

Because of the work by Beltrami, Klein, and Poincaré in Section 13.4, we know that the Parallel Postulate is independent (page 324) of Euclid's other postulates. This means that the Parallel Postulate can neither be proven true nor proven false from Euclid's first four assumptions. It is important for any proposition in a set of postulates to have this property because we never want to assume a proposition that could have been proven from the others. We say that a set of propositions is **independent** if every proposition of the set is independent of the others. To prove that a set of propositions $\{p_1, p_2, \ldots, p_k\}$ is independent, for each i we must show that both

$$\{p_1, p_2, \ldots, p_i, \ldots, p_k\}$$

and

$$\{p_1, p_2, \ldots, \textit{not } p_i, \ldots, p_k\}$$

are consistent. In this way, neither *not* p_i nor p_i necessarily follow from the other postulates.

To prove that the set of projective postulates is independent, we first observe that the Fano plane shows that the postulates are consistent. It remains to show that the negation of any of the projective postulates plus the remaining three is a consistent set of propositions. The diagram of Figure 14.3(a) shows that it is possible that the first postulate is false while the others are true, and Figure 14.3(b) shows that it is possible for the third postulate to be false with the others true. The Euclidean plane is a model in which Postulates 1, 3, and 4 are satisfied but Postulate 2 is not because there are parallel lines in the Euclidean plane. The empty set is a model in which the last postulate is false because that postulate entails the existence of objects in the geometry. The others are **vacuously true** on the empty set. This refers to the fact that a universal sentence can be written as a conditional. For example, Postulate 14.1.1.1 can be stated as

if P and Q are distinct points in $\mathcal{P}$, there exists a unique line l in $\mathcal{L}$ such that P and Q are incident with l.

If $\mathcal{P} = \varnothing$, the antecedent of the conditional is false, and this implies that the conditional is true (page 38).

Figure 14.3 Independence of the projective postulates.

Exercises

1. Given the following set of postulates for **incidence geometry**:

   Postulate 1. There exist at least three points.
   Postulate 2. Two distinct points are on exactly one line.
   Postulate 3. There are at least two points on every line.
   Postulate 4. For every line l, there is a point not on l.

   (a) Show that this is a consistent set of postulates using a finite model.
   (b) Find an infinite model for this geometry.
   (c) Show that this is an independent set of postulates.
   (d) Determine whether incidence geometry is a projective geometry.

2. Given the following set of postulates for **three-point geometry**:

   Postulate 1. There exist exactly three points.
   Postulate 2. Two distinct points are on exactly one line.
   Postulate 3. Every two distinct lines are on at least one point.
   Postulate 4. For every line l, there is a point not on l.

   (a) Show that this is a consistent set of postulates.
   (b) Show that this is an independent set of postulates.
   (c) Determine whether three-point geometry is a projective geometry.

3. Prove the following theorems in three-point geometry.
   (a) Two distinct lines are on exactly one point.
   (b) There exist exactly three lines.
   (c) Lines cannot contain three distinct points.
   (d) There exists a set of two lines containing all of the points.
   (e) There exists a set of two points such that each line lies on at least one of the points.

4. Given the following set of postulates for **four-line geometry**:

   Postulate 1. There exist exactly four lines.
   Postulate 2. Two distinct lines intersect on exactly one point.
   Postulate 3. Every point is on exactly two lines.

   (a) Show that this is a consistent set of postulates.
   (b) Show that this is an independent set of postulates.
   (c) Determine whether four-line geometry is a projective geometry.

5. Given the following set of postulates for **Fano's geometry**:

   Postulate 1. There exists at least one line.
   Postulate 2. Every line contains exactly three points.
   Postulate 3. Not all points are on the same line.
   Postulate 4. Two distinct points are on exactly one line.
   Postulate 5. Two distinct lines intersect in at least one point.

(a) Show that this is a consistent set of postulates.
(b) Show that this is an independent set of postulates.
(c) Determine whether Fano's geometry is a projective geometry.

6. Prove the following theorems in Fano's geometry:
   (a) Every two lines have exactly one point in common.
   (b) There exist exactly seven points and seven lines.
   (c) Each point lies on exactly three lines.
   (d) Lines through any given point contain all of the points.
   (e) For any pair of points, there is exactly two lines not containing either point.
   (f) Given a set of three lines not all containing the same point, there exists exactly one point not on any of the three lines.

7. **Young's geometry** shares the first four postulates of Fano's geometry, but Postulate 5 is replaced with

> **Postulate 5.** If a point does not lie on a given line, there exists exactly one line on the point that does not intersect the given line.

   (a) Show that this is a consistent set of postulates.
   (b) Show that this is an independent set of postulates.
   (c) Determine whether Young's geometry is a projective geometry.

8. Show that the Fano plane is the smallest model of projective geometry.

9. Show that two lines in a projective plane intersect in exactly one point.

10. Prove Theorem 14.1.2.

11. Let $(\mathcal{P}, \mathcal{L})$, $(\mathcal{P}', \mathcal{L}')$, and $(\mathcal{P}'', \mathcal{L}'')$ be projective planes. Suppose that

$$\phi : \mathcal{P} \to \mathcal{P}'$$

and

$$\psi : \mathcal{P}' \to \mathcal{P}''$$

are collineations. Show that following:
   (a) ϕ^{-1} is a collineation.
   (b) $\psi \circ \phi$ is a collineation.

12. Do any of the five geometries defined in this exercise set have two nonisomorphic models? If so, which ones?

14.2 DUALITY

Throughout this section we assume that all points and lines are from the projective plane $(\mathcal{P}, \mathcal{L})$. We begin this section by proving a sequence of four theorems that follow quickly from the definition of a projective plane.

■ THEOREM 14.2.1

For all distinct l, $m \in \mathscr{L}$, there is a unique point $P \in \mathscr{P}$ so that P is on l and m.

PROOF

Let l, $m \in \mathscr{L}$. By Postulate 14.1.1.2 we know that there exists a point P that is incident with l and m. We must show that P is unique, so suppose that there exists another point Q incident with l and m that is different from P. This means that we have two distinct points on two distinct lines, which contradicts Postulate 14.1.1.1. ■

■ THEOREM 14.2.2

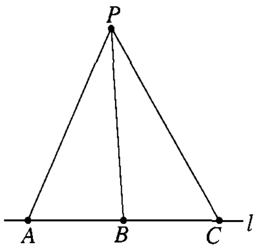
For all distinct P, $Q \in \mathscr{P}$, there is a line incident with both P and Q.

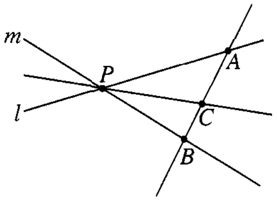
PROOF

This is just Postulate 14.1.1.1 without the uniqueness condition. ■

■ THEOREM 14.2.3

Every point is incident with at least three lines.





PROOF

Let P be a point and let l and m be the two lines guaranteed by Postulate 14.1.1.4. We have two cases to consider.

- Suppose that P is not on l. We know by Postulate 14.1.1.3 that l has three points on it. Call them A, B, and C. By Postulate 14.1.1.1 we may join $\overline{PA}$, $\overline{PB}$, and $\overline{PC}$. None of these lines equals l because they contain P but l does not. We also see that $\overline{PA}$, $\overline{PB}$, and $\overline{PC}$ are all distinct because if we suppose that any two of these lines are the same, there would be a pair of points on two distinct lines contradicting Postulate 14.1.1.1. For example, if $\overline{PA}$ is the same line as $\overline{PB}$, we conclude that A and B are on both $\overline{PA}$ and l.

- Now let P be on l. If P is not on m, we may construct three lines as we did in the first part, so suppose that P is also on m. We know that there is a point A on l and a B on m that are both different from P. Join $\overline{AB}$ by Postulate 14.1.1.1, and by Postulate 14.1.1.3 find another point C on

$\overline{AB}$. Join $\overline{PC}$. This is the third line through P because if $\overline{PC}$ were either equal to l or m, we would have two distinct points on two distinct lines. ■

■ **THEOREM 14.2.4**

There are at least two points.

PROOF

Postulate 14.1.1.4 tells us that there is a line, and by Postulate 14.1.1.3 there are at least three points on that line. Therefore, there are at least two points. ■

When we compare the four theorems with Postulates 14.1.1, we see that they are basically the same except that the words *point* and *line* have been interchanged. What this means is that every theorem about the projective plane has a corresponding theorem called its **dual** that is obtained from the original by exchanging every concept related to the word *point* with the corresponding concept related to the word *line*. This dual follows automatically without further proof once the original theorem is proven. This is a very important property of projective geometry called the **principle of duality**.

The principle of duality was discovered by Poncelet but not without controversy. In 1810 an artillery officer by the name of Joseph-Diez Gergonne published the first privately published journal of mathematics. He titled it the *Annales de Mathématiques Pures et Appliquées*. Gergonne was a fine mathematician and a strong supporter of analytic methods. Poncelet, on the other hand, was a staunch defender of the synthetic. These two soon became point men in the synthetic–analytic debate that had previously embroiled Klügel and Kästner with the English (page 355). At first their competition was civil, with both publishing papers espousing their points of view in Gergonne's *Annales* in 1818. Needless to say, the controversy was not settled, and years later, in 1826, matters heated up when both men claimed priority in the discovery of the principle of duality. Gergonne claimed that he had proven it using analytic methods, while Poncelet insisted that he had discovered duality during a study of the conic sections. The reality of the situation was that although the term *dual* was due to Gergonne, it was Poncelet who was first (Boyer and Merzbach 1991, 506–507, 536; Kline 1972, 845).

The Complete Quadrilateral

To illustrate the principle of duality, we consider two pairs of geometric figures. The first pair is the **triangle**,

three noncollinear points that join to form three sides,

and the **trilateral**,

three nonconcurrent lines that meet to form three vertices.

These definitions are duals of each other. One sentence is formed from the other by making the replacement:

point $\longleftrightarrow$ line
join $\longleftrightarrow$ meet
vertex $\longleftrightarrow$ side
collinear $\longleftrightarrow$ concurrent

When we draw both of these figures, we find that they are the same. We say that the figures are **self-dual**.

The second pair involves the complete quadrangle. We repeat its definition:

■ DEFINITION 14.2.5

Let A, B, C, and D be four points in a plane, no three of which are collinear. The configuration that consists of these four points and the six lines determined by all possible pairs of the points is called the **complete quadrangle** $ABCD$.

Since being *concurrent* is the dual of being *collinear*, we may define the dual of the complete quadrangle.

■ DEFINITION 14.2.6

Let a, b, c, and d be four lines in a plane, no three of which are concurrent. The configuration that consists of these four lines and the six points determined by all possible pairs of the lines is called the **complete quadrilateral** $abcd$.

Compare the following with the content on page 315. The lines of the complete quadrilateral $abcd$ are called its **sides**, and the points of $abcd$ are its **vertices**. The complete quadrilateral $abcd$ is illustrated in Figure 14.4. It consists of the four lines a, b, c, and d and the six vertices

$$ab,\ bc,\ cd,\ ad,\ ac,\ bd,$$

where ab represents the intersection of lines a and b. Two vertices are said to be **opposite** if they do not share a common side. There are three pairs of opposite

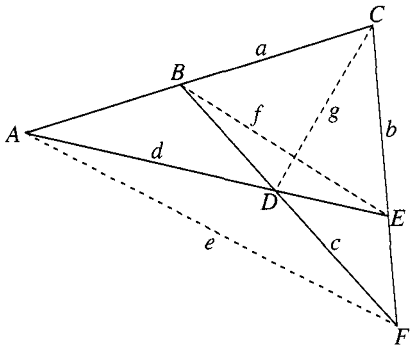


Figure 14.4 A complete quadrilateral $abcd$.

vertices. They lie on three lines called **diagonal lines**. The intersection of these lines form the **diagonal trilateral** of $abcd$. The diagonal trilateral of the quadrilateral in Figure 14.4 is Δefg.

Harmonic Sets

In Books III and IV of the *Conic Sections*, Apollonius determines necessary and sufficient conditions for a line through a point outside a conic section to be tangent to that section (Kline 1972, 96–97). Let A be a point external to a conic such that $\overline{AP}$ and $\overline{AQ}$ are tangent to the given conic section (Figure 14.5). Suppose that P and Q are the points of tangency. Join $\overline{PQ}$. This segment is called the **polar** of the **pole** A. Through any point C on $\overline{PQ}$, draw the line that joins A and C and let B and D be the points of intersection of this line with the conic. Apollonius showed that

$$\frac{AB}{AD} = \frac{CB}{CD}. \tag{14.1}$$

The phrase that is traditionally used to describe this proportion is:

A divides $\overline{BD}$ externally in the same ratio as C divides it internally.

Conversely, suppose that we have a point outside a conic and want to find the tangents to the conic that pass through the point. To do this, we again let A be off the conic and external to it. Draw a line through A that meets the conic at B and D. Draw another line through A that intersects the conic at B' and D' (Figure 14.5). On $\overline{BD}$ find C such that Equation 14.1 holds and find C' on $\overline{B'D'}$ so that

$$\frac{AB'}{AD'} = \frac{C'B'}{C'D'}.$$

Apollonius showed that the line through C and C' intersects the conic section at the points P and Q, respectively, so that $\overline{AP}$ and $\overline{AQ}$ are tangent lines.

Now let us change our perspective. Take quadrangular set Q$(ABC,\ EDF)$. By Theorem 9.4.5,

$$\frac{AB \cdot EB}{AD \cdot ED} = \frac{CB \cdot FB}{CD \cdot FD}.$$

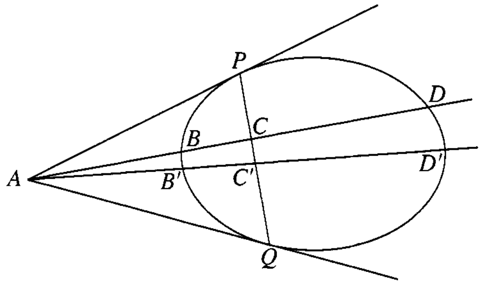

Figure 14.5 A pole and polar of a conic section.

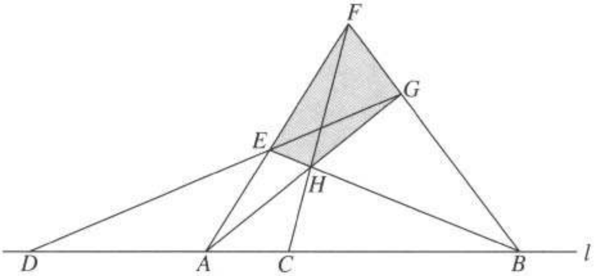

Figure 14.6 H(AB, CD).

Suppose that point A coincides with E and that C coincides with F. We then have

$$\frac{AB \cdot AB}{AD \cdot AD} = \frac{CB \cdot CB}{CD \cdot CD},$$

and this is equivalent to Equation 14.1. Desargues called the original points A, B, C, and D four points in involution (Exercise 4 of Section 9.4). We have a different name for this relation. It is defined in terms of a modified quadrangular set and illustrated in Figure 14.6.

■ DEFINITION 14.2.7

The four collinear points A, B, C, D form a **harmonic set of points** if there is a complete quadrangle such that points A and B are two of the vertices of its diagonal triangle and points C and D are on the sides through the third vertex of the diagonal triangle. The harmonic set of points is denoted by H(AB, CD).

Observe that

$$\mathsf{H}(AB, CD) \text{ if and only if } \mathsf{Q}(ABC, ABD).$$

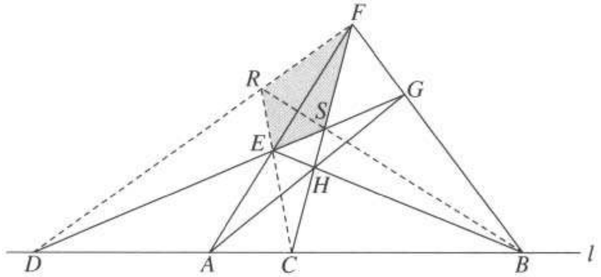
Moreover, like the notation for involutions (page 313), there are permutations of the points of a harmonic set that immediately from the definition also form harmonic sets, but H(CD, AB) is not one of them. That H(AB, CD) implies H(CD, AB) requires proof.

■ THEOREM 14.2.8

For any four points A, B, C, D, if H(AB, CD), then H(CD, AB).

PROOF

Let A, B, C, and D be collinear such that H(AB, CD). This means there exists complete quadrangle $EFGH$ such that A is the intersection of $\overline{EF}$ and $\overline{HG}$, B is the intersection of $\overline{EH}$ and $\overline{FG}$, C is on $\overline{FH}$, and D is on $\overline{EG}$. To prove H(CD, AB) we must find a complete quadrangle such that C and D

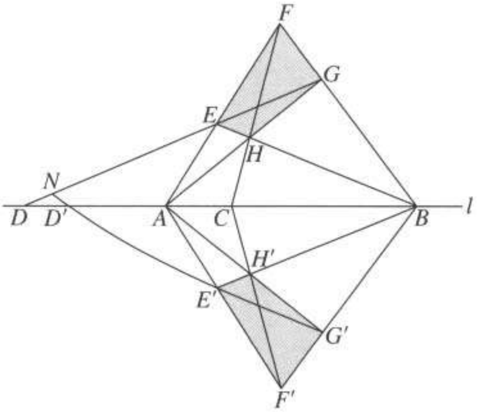


are vertices of its diagonal triangle and A and B are on lines through the third vertex of its diagonal triangle. To do this, join $\overline{DF}$ and $\overline{EC}$. Extend $\overline{EC}$ to meet $\overline{DF}$ at R. Let S be the intersection of $\overline{DG}$ and $\overline{CF}$. We want R, S, and B to be collinear. To obtain this, consider $\triangle REF$ and $\triangle SHG$. Notice that $\overline{RF}$ and $\overline{SG}$ meet at D, $\overline{EF}$ and $\overline{HG}$ meet at A, and $\overline{RE}$ and $\overline{SH}$ meet at C. This means that the points of intersection of pairs of corresponding sides of the two triangles are collinear. Therefore, the lines joining corresponding vertices are concurrent by Desargues' Theorem (9.3.2). Since we know that $\overline{EH}$ and $\overline{FG}$ already intersect at B, it must be the case that the $\overline{RS}$ produced will contain B. We conclude that $RFSE$ is the desired complete quadrangle because C and D are vertices of its diagonal triangle and A and B are on lines that intersect the diagonal triangle's third vertex. Therefore, $\mathsf{H}(CD,\ AB)$. ■

Choose three points A, B, and C on a line l. We can prove that there is a unique point D on l so that $\mathsf{H}(AB,\ CD)$. The point D is called the **harmonic conjugate** of C with respect to A and B.

■ THEOREM 14.2.9

Let A, B, and C be three points on a line l. There exists exactly one point D on l such that $\mathsf{H}(AB,\ CD)$.



PROOF

Let l be a line and take A, B, and C to be points on l. We first show that the desired D exists. Take a point F not on l. After joining $\overline{FB}$, pick G on that segment. Join $\overline{AG}$ and $\overline{FC}$ and let these segments intersect at H (Theorem 9.2.8). Join $\overline{AF}$ and $\overline{BH}$, producing $\overline{BH}$ to meet $\overline{AF}$ at E. Take the point D to be the intersection of l and $\overline{GE}$ produced. Since $EFGH$ is a complete quadrangle, we see that $\mathsf{H}(AB,\ CD)$.

To show that D is unique, repeat the construction so that we have complete quadrangle $E'F'G'H'$ with $\overline{E'F'}$, $\overline{F'G'}$, and $\overline{H'F'}$ intersecting l at A, B, and C, respectively, but $\overline{E'G'}$ meeting l at D', which is different from D. By Theorem 9.2.8, there is a point N that is incident with both $\overline{GD}$ and $\overline{G'D'}$. First consider $\triangle EFH$ and $\triangle E'F'H'$. Since their corresponding sides intersect at A, C, and B on line l, we conclude by Desargues' Theorem (9.3.2) that $\overline{EE'}$, $\overline{HH'}$, and $\overline{FF'}$ are concurrent (not pictured). The same argument using $\triangle FGH$ and $\triangle F'G'H'$ allows us to conclude that $\overline{HH'}$, $\overline{FF'}$, and $\overline{GG'}$ are concurrent. Therefore, the lines joining corresponding vertices of $\triangle HEG$ and $\triangle H'E'G'$ are concurrent, so by another application of Desargues' Theorem (9.3.1), points N, A, and B are collinear. This means that N must be on l, so $D = D'$. ■

The dual of a harmonic set of points is a harmonic set of lines.

■ DEFINITION 14.2.10

The four concurrent lines a, b, c, d form a **harmonic set of lines** if there exists a complete quadrilateral such that a and b are two of the sides of its diagonal trilateral and c and d are on the points on the third side of the diagonal trilateral. When a, b, c, and d form a harmonic set in this fashion, we write $\mathsf{H}(ab,\ cd)$.

Exercises

1. Given ellipse $x^2 + 4y^2 = 16$, find
   (a) the polar of $(-7,\ 0)$.
   (b) the pole of the vertical polar at $x = 2$.
   (c) the pole of the segment that joins the points of intersection of $y = 2x + 3$ and the ellipse.

2. Write the duals of each of the following sentences.
   (a) *There exist at least two lines.*
   (b) *There are at least two lines on every point.*
   (c) *Not all points lie on the same line.*
   (d) *Two distinct lines intersect in a unique point.*
   (e) *The line intersects one of the sides of a complete quadrangle.*
   (f) *The line joining two points contains the third point.*
   (g) *All points lie on either the first or the second line.*

3. Brianchon's Theorem is the dual of Pascal's Theorem (9.3.5). State Brianchon's Theorem.

4. Let $\mathsf{H}(AB,\ CD)$. Write seven other orders of points A, B, C, and D that form harmonic sets.

5. Construct a complete quadrangle given its diagonal triangle and one vertex.

6. Let A, B, C, and D be collinear points. Find P and Q such that $\mathsf{H}(AB,\ PQ)$ and $\mathsf{H}(CD,\ PQ)$.

7. The **cross ratio** of the four collinear points A, B, C, and D is

$$(AB,\ CD) = \frac{AC \cdot BD}{AD \cdot BC}.$$

Show that $\mathsf{H}(AB,\ CD)$ if and only if $(AB,\ CD) = 1$.

8. Let A, B, C, and D be collinear. Show the following:
   (a) $(AB,\ CD) = (CD,\ AB)$.
   (b) $(AB,\ DC) = 1/(AB,\ CD)$.
   (c) Use these two results to confirm the findings of Exercise 4.

9. Assume that for any ordinary points A and B and ideal point Ω, $A\Omega = B\Omega$ because both distances are infinite. With this in mind, prove that if $\mathsf{H}(AB,\ CD)$ and C is the midpoint of $\overline{AB}$, then D is an ideal point.

10. Let A, B, C, D, E be collinear. Show that:
   (a) $(AB,\ CD) = (AB,\ CE) \cdot (AB,\ ED)$.
   (b) $(AB,\ CD) = (AE,\ CD) \cdot (EB,\ CD)$.
   (c) $(AB,\ DE) = (AB,\ CD)/(AB,\ CE)$

11. Let O, A, B, C, A', B', and C' be collinear and

$$OA \cdot OA' = OB \cdot OB' = OC \cdot OC'.$$

Prove that $\mathsf{H}(AB',\ BC)$ if and only if $\mathsf{H}(A'B,\ B'C')$.

12. Prove that $\mathsf{H}(AB,\ CD)$ if and only if

$$\frac{1}{AB} = \frac{1}{2}\left(\frac{1}{AC} + \frac{1}{AD}\right).$$

13. For the given sets of three points, find the Cartesian coordinates of the harmonic conjugate of C with respect to A and B.
   (a) $A(0,\ 0)$, $B(3,\ 0)$, $C(8,\ 0)$
   (b) $A(-1,\ 3)$, $B(1,\ 2)$, $C(5,\ 0)$

14. Write the duals for Theorems 14.2.8 and 14.2.9.

15. Let a, b, and c be concurrent lines. Explain the procedure for finding the line d that is the harmonic conjugate of the given lines.

16. Prove that given concurrent lines a, b, and c, there exists a unique line d such that $\mathsf{H}(ab, cd)$.

17. Suppose that l intersects concurrent lines a, b, c, and d in points A, B, C, and D. Prove that $\mathsf{H}(AB, CD)$ if and only if $\mathsf{H}(ab, cd)$.

14.3 PERSPECTIVITY

Poncelet made new contributions to the projection of Desargues. Let $(\mathcal{P}, \mathcal{L})$ be a projective plane, and take $l, m \in \mathcal{L}$, $O \in \mathcal{P}$ but O is concurrent with neither l nor m. Define $T : l \to m$ such that $T(A) = A'$ if and only if A and A' are collinear with O (Figure 14.7). The function T is called a **central perspectivity** and O is the **center of perspectivity**. We represent $T(A) = A'$ by

$$A \overset{O}{\barwedge} A'.$$

Read this as "A and A' are in **perspective** with respect to O."

The central perspectivity is the projection of the earlier projective geometers (Section 9.1), and it is an invertible function.

■ THEOREM 14.3.1

A central perspectivity is a one-to-one correspondence.

PROOF

Let $T : l \to m$ be a central perspectivity with center O. Let A and B be on l and assume that

$$T(A) = T(B) = A'.$$

If $A \neq B$, we conclude that there are two distinct lines that pass through O and A'. This contradicts Postulate 14.1.1.1. Hence, $A = B$, and we conclude that T is one-to-one. To prove that T is onto, let A' be incident with m and choose A to be the intersection of $\overline{OA'}$ with l. This means that $T(A) = A'$. ■

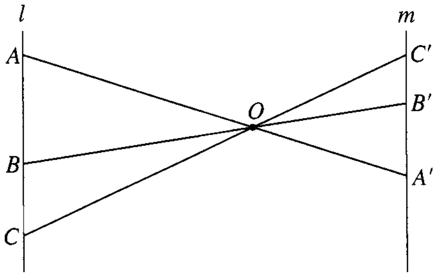


Figure 14.7 A central perspectivity.

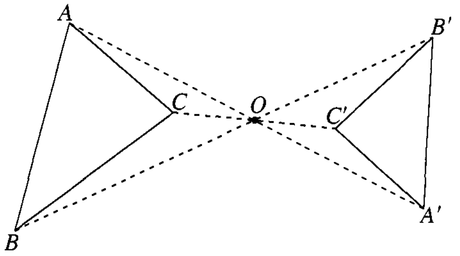
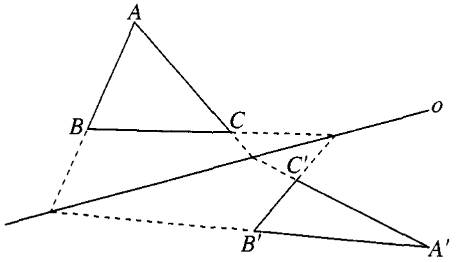


(a) $\triangle ABC$ and $\triangle A'B'C'$ are perspective from P



(b) $\triangle ABC$ and $\triangle A'B'C'$ are perspective from p

Figure 14.8 Desargues' Theorem.

Although a perspectivity is a function between two lines, there is a natural way to generalize it to plane figures (Figure 14.8).

■ DEFINITION 14.3.2

Two figures in the plane are **perspective from a point** if there exists a point O in the plane such that any line joining corresponding points from the figures contain O.

The dual of two figures perspective from a point is perspective from a line.

■ DEFINITION 14.3.3

Two figures in the plane are **perspective from a line** if there exists a line o in the plane such that all corresponding lines from the figures intersect at o. The line o is called the **axis of perspectivity**.

The new terminology allows us to restate Desargues' Theorem (9.3.1 and 9.3.2). Remember that it was required in the proof to pass to the third dimension. Since we are limiting ourselves to the projective plane, a proof would require an additional postulate justifying a key step (Coxeter 2003, 18–20). We will, nonetheless, still label it as a theorem.

THEOREM 14.3.4 [Desargues]

Two triangles are perspective from a point if and only if they are perspective from a line.

Projectivities

Since perspectivities are functions, we can compose them under the right conditions. This amounts to taking a sequence of points O_1, O_2, ..., O_k and lines l_1, l_2, ..., l_k, l_{k+1} such that O_i is not on l_i or l_{i+1} and defining perspectivities $T_i : l_i \to l_{i+1}$ with center of perspectivity O_i. The resulting function plays a central role in the study of projective geometry.

DEFINITION 14.3.5

The composition of central perspectivities is called a **projectivity**.

Since the composition of one-to-one and onto functions is one-to-one and onto, we conclude that projectivities are one-to-one correspondences and thus invertible.

As an example, let l and m be two lines with A, B, $C \in l$ and A', B', $C' \in m$ (Figure 14.9). We claim that we can find a projectivity T between l and m such that

$$T(A) = A', T(B) = B', T(C) = C',$$

and T is the composition of two central perspectivities. To do this, find C'' not on l or m. Join $\overline{AA'}$ and $\overline{CC''}$ and let O be their intersection. Let B'' be the intersection of $\overline{BO}$ and $\overline{C''A'}$. Now join $\overline{C''C'}$ and $\overline{B''B'}$ and let their intersection by O'. We now have two central perspectivities, one with center O and the other with center O'. Their composition is our desired T because

$$A \overset{O}{\barwedge} A' \overset{O'}{\barwedge} A', \; B \overset{O}{\barwedge} B'' \overset{O'}{\barwedge} B', \text{ and } C \overset{O}{\barwedge} C'' \overset{O'}{\barwedge} C'.$$

For a second example we write the identity map on a line l as the composition of three central perspectivities. Let A, B, and C be points on l (Figure 14.10). Take

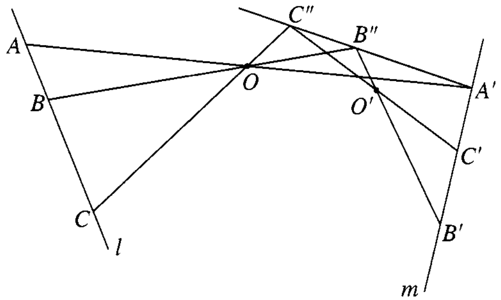


Figure 14.9 A projectivity that is the composition of two central perspectivities.

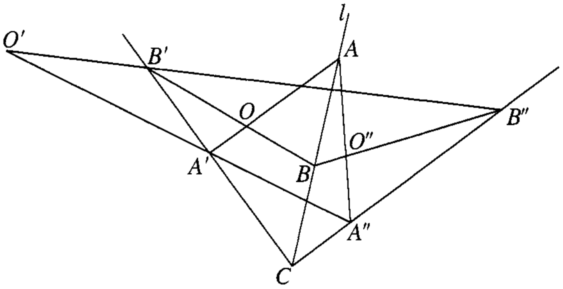

Figure 14.10 The identity map is the composition of three perspectivities.

B' and B'' not on l. Let A' be on $\overline{B'C}$ but not equal to either B' or C. Let O be the intersection of $\overline{A'A}$ with $\overline{B'B}$. Find a new point A'' on $\overline{CB''}$ and let O'' be the intersection of $\overline{AA''}$ and $\overline{BB''}$. Finally, let O' be the intersection of $\overline{A'A''}$ and $\overline{B'B''}$. This defines three perspectivities. Their centers are O, O', and O'', so we may write

$$A \overset{O}{\barwedge} A' \overset{O'}{\barwedge} A'' \overset{O''}{\barwedge} A$$

and similarly for B and C. These three points are invariants.

DEFINITION 14.3.6

A point that is mapped to itself under a projectivity is called **invariant**.

The question now is whether the composition of these three perspectivities yields the identity on l. If we pick a few random points from l and apply the projectivity (Exercise 14), we discover that the checked points are invariant. This, of course, is far from a proof.

Harmonic Nets

As Desargues was interested in what properties were preserved by projections, modern projective geometry asks what properties are preserved by projectivities. These are essentially the same question, so we should expect the next theorem. Compare this with Theorem 9.4.2. We state it without proof.

THEOREM 14.3.7

Let T be a projectivity with A, B, C, D in the domain of T. If $\mathsf{H}(AB,\ CD)$, then $\mathsf{H}(T(A)T(B),\ T(C)T(D))$.

Suppose that T is a projectivity with the line l as its domain. Take A, B, $C \in l$. By Theorem 14.2.9, there exists a unique $D \in l$ such that $\mathsf{H}(AB,\ CD)$. Therefore, by Theorems 14.3.7 and 14.2.9, $T(D)$ is the harmonic conjugate of $T(C)$ with respect to $T(A)$ and $T(B)$, and $T(D)$ could equal no other point. Therefore,

T is determined uniquely on $\{A, B, C, D\}$
because it is determined on $\{A, B, C\}$.

There also are unique points E and F in the domain of T and not among $\{A, B, C, D\}$ such that $\mathsf{H}(AC, BE)$ and $\mathsf{H}(BC, AF)$ (Exercise 15). This means that $T(E)$ and $T(F)$ are determined uniquely because projectivities preserve harmonic sets. Hence,

T is determined uniquely on $\{A, B, C, D, E, F\}$
because it is determined on $\{A, B, C\}$.

We may continue in this manner and either exhaust all of the points of l or find a countably infinite collection of points of l on which T is determined uniquely. Call the resulting set a **harmonic net** of l. All of this is restated as the next theorem.

■ THEOREM 14.3.8

There exists a unique projectivity that maps three distinct points of a harmonic net onto three distinct points in a given order.

The identity map I on l is a projectivity (Exercise 8) that leaves all points on a harmonic net invariant. If a projectivity T with domain l leaves three points invariant on the same harmonic net, we know that T and I must agree on all points of the harmonic net. This proves the corollary.

■ COROLLARY 14.3.9

A projectivity that leaves three points invariant on a harmonic net of points leaves all points invariant on the same harmonic net.

The corollary also implies Theorem 14.3.8 (Exercise 18), so the two statements are equivalent. Our ultimate goal is to generalize these equivalent statements so that they hold on the entire domain of a projectivity. If the domain is finite, the domain is a harmonic net, and the generalization follows easily. Otherwise, we are left in an impossible situation. It turns out that any attempt at generalizing Theorem 14.3.8 or its corollary requires knowing that the harmonic net is distributed on the domain of a projectivity in much the same way that the rational numbers are spread out on the real line. This seems to require the concepts of distance and convergence that have been deliberately left out of the projective postulates. Therefore, since we think both generalizations are reasonable, we will choose one of them as an assumption and prove that the other follows.

■ POSTULATE 14.3.10

If a projectivity leaves three points invariant, it is the identity.

With this we may prove the central theorem of Poncelet's new geometry.

■ THEOREM 14.3.11 [Fundamental Theorem of Projective Geometry]

A projectivity is determined uniquely by three points.

PROOF

Let T and T' be projectivities with domain l. Assume that $T(A) = T'(A) = A'$, $T(B) = T'(B) = B'$, and $T(C) = T'(C) = C'$, but $T(D) = D'$ and $T'(D) = D''$ with $D' \neq D''$. We know that T^{-1} exists (Theorem 14.3.1), so we check:

$$(T' \circ T^{-1})(A') = T'(T^{-1}(A')) = T'(A) = A'.$$

Similarly, B' and C' are invariant under $T' \circ T^{-1}$. But $(T' \circ T^{-1})(D') = D''$. This contradicts Postulate 14.3.10 because $T' \circ T^{-1}$ is a projectivity that holds three points invariant but is not the identity. ■

The Fundamental Theorem answers the question posed by the example on page 504 in the affirmative because the composition defined there and the identity are projectivities that agree on three points. The Fundamental Theorem also shows that the projectivity found in the first example on page 503 is unique (Exercise 17).

Exercises

1. Show that a central perspectivity has exactly one center if the perspectivity's domain and range are different.

2. Is it possible for a central perspectivity to have two centers if its domain and range share a point?

3. Prove that a central perspectivity is the identity map if the domain equals the range.

4. Let l and m be lines with $A,\ B \in l$ and $A',\ B' \in m$. Find a central perspectivity with center O such that

$$A \overset{O}{\barwedge} A' \text{ and } B \overset{O}{\barwedge} B'.$$

5. Show that a central perspectivity is determined uniquely by two points.

6. The dual of a central perspectivity is an **axial perspectivity**.
   (a) Define an axial perspectivity.
   (b) Without simply writing the dual of Theorem 14.3.1, show that an axial perspectivity is a one-to-one correspondence.
   (c) What is the dual of a projectivity?

7. Define central perspectivity and axial perspectivity using the terms *pencil* and *range*.

8. Show that the identity map on a line is a projectivity.

9. Prove that a projectivity $T : l \to l$ can be written as the composition of three central perspectivities.

10. Let T be a projectivity that leaves exactly one point invariant. Prove that T is a perspectivity.

11. Define $(ABCD) \barwedge (A'B'C'D')$ to mean that there exists a projectivity T such that $T(A) = A'$, $T(B) = B'$, $T(C) = C'$, and $T(D) = D'$. Show for any collinear A, B, C, and D, we have $(ABCD) \barwedge (BADC) \barwedge (CDAB) \barwedge (DCBA)$.

12. Prove that $(AECF) \barwedge (BDCF)$ if and only if $\mathsf{Q}(ABC,\ DEF)$.

13. Draw an example of a projectivity that leaves exactly two points invariant.

14. Choose a point on l in Figure 14.10 and confirm that it is invariant under the composition of the three perspectivities.

15. Assume $\mathsf{H}(AB,\ CD)$, where A, B, C, and D are on a line l. Show that there exists E and F on l and not among $\{A,\ B,\ C,\ D\}$ such that $\mathsf{H}(AC,\ BE)$ and $\mathsf{H}(BC,\ AF)$.

16. Prove that a harmonic net is determined uniquely by three points.

17. Draw a line l containing the points A, B, and C and another line containing A', B', and C'. Let T and T' be projectivities such that

$$T(A) = T'(A) = A',\ T(B) = T'(B) = B', \text{ and } T(C) = T'(C) = C'.$$

Draw T as the composition of two central perspectivities with centers O and O' as on page 503. Also, draw T' as the composition of two central perspectivities with centers P and P'. Pick a point D on l and confirm that $T(D) = T'(D)$.

18. Prove that Corollary 14.3.9 implies Theorem 14.3.8.

14.4 HOMOGENEOUS COORDINATES

To assign points using Cartesian coordinates, we fix a reference point called the origin, draw two perpendicular lines through it, and then by measuring distances horizontally and vertically along a grid of parallel lines, a point is labeled using an ordered pair consisting of those distances. But how do you assign coordinates in a system that does not allow for angle measure, has no parallel lines, and has no concept of distance? We use triangulation and the methods of linear algebra.

Points and Lines

Let E_1, E_2, and E_3 be points in a projective plane. Label E_1 as $(1,\ 0,\ 0)$, E_2 as $(0,\ 1,\ 0)$, and E_3 as $(0,\ 0,\ 1)$, as in Figure 14.11. Join $\overline{E_1E_2}$, $\overline{E_2E_3}$, and $\overline{E_1E_3}$ to form the **reference triangle**. Finding new points on these three lines requires the introduction of a fourth point E that we will label $(1,\ 1,\ 1)$ and place in the middle of the reference triangle. We call E the **unit point**. Joining $\overline{EE_1}$ results in a new point A on $\overline{E_2E_3}$ because any two lines in a projective plane intersect in a point (Postulate 14.1.1.2). Similarly, $\overline{EE_2}$ and $\overline{EE_3}$ result in points B and C on $\overline{E_1E_3}$ and $\overline{E_1E_2}$, respectively.

We know that given three points on a line, we can construct another point so that the four points are a harmonic set. Since the harmonic conjugate is unique, we have

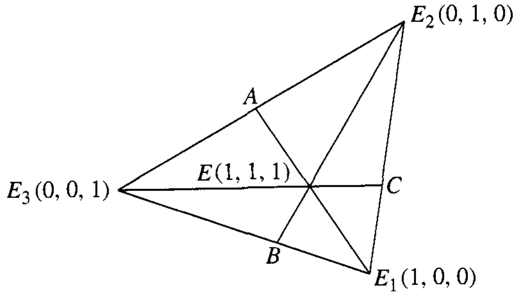

Figure 14.11 The reference triangle and the unit point.

a method, without a metric for either segments or angles, to generate points uniquely in a projective plane. It works like this. Start with three collinear points X, X_0, and X_1. If we choose X_2 such that $\mathsf{H}(XX_1, X_0X_2)$, X_2 will be between X_1 and X (Figure 14.12). Similarly, we may find X_3 between X_2 and X if $\mathsf{H}(XX_2, X_1X_3)$. We thus find a sequence

$$X_1,\ X_2,\ X_3,\ \ldots,\ X_n,\ \ldots$$

continuing indefinitely toward X provided that

$$\mathsf{H}(XX_{n-1},\ X_{n-2}X_n)$$

for $n > 2$. To find a point $X_{(m+n)/2}$ between a pair of points X_m and X_n, use

$$\mathsf{H}(XX_{(m+n)/2},\ X_mX_n).$$

If the process continues indefinitely, it will generate a harmonic net, which fills the line as the rational numbers fill $\mathbb{R}$. For this reason a harmonic net is often called a **net of rationality**.

Now that we know how to find points on a line in the projective plane, we define an analytic geometry so that we can write equations to identify the points and lines. For every point P in the plane, assign a set of ordered triples of the form

$$(kx_1,\ kx_2,\ kx_3),$$

where kx_1, kx_2, kx_3 are real numbers, not all zero. For example, the ordered triples $(1,\ 2,\ 3)$ and $(4,\ 8,\ 12)$ identify the same point. Because all nonzero multiples of $(x_1,\ x_2,\ x_3)$ represent the same point, we say that $(kx_1,\ kx_2,\ kx_3)$ is written using **homogeneous coordinates**. Lines in this system will be identified by equations of the form

$$a_1x_1 + a_2x_2 + a_3x_3 = 0,$$

where a_1, a_2, and a_3 are not all zero. This resembles the equation for a line using Cartesian coordinates except that the third term is not a constant.

To see how this works, let us find the equation for the line joining $(1, 2, 3)$ and $(2, 4, 1)$. To accomplish this, we must find real numbers a_1, a_2, and a_3 so that

$$\begin{aligned} a_1 + 2a_2 + 3a_3 &= 0, \\ 2a_1 + 4a_2 + a_3 &= 0. \end{aligned}$$

This is equivalent to forming the matrix

$$\begin{bmatrix} 1 & 2 & 3 \\ 2 & 4 & 1 \end{bmatrix},$$

and putting it into row-reduced echelon form,

$$\begin{bmatrix} 1 & 2 & 0 \\ 0 & 0 & 1 \end{bmatrix}.$$

From this we find that the coefficients for the equation of the line are

$$a_1 = -2k, a_2 = k, \text{and } a_3 = 0$$

for all nonzero k. We arbitrarily choose $k = -1$, so the equation for the line between $(1, 2, 3)$ and $(2, 4, 1)$ can be written as

$$2x_1 - x_2 = 0.$$

Any point (x_1, x_2, x_3) that satisfies this equation will lie on the line. Because of the principle of duality, this line should receive a name like the points. The natural choice is to use the coefficients, so call the line $[2, -1, 0]$. Because of the parameter k, each triple $[2k, -k, 0]$ names the same line for all possible values of $k \neq 0$. Evidently, the sides of the reference triangle are $[1, 0, 0]$, $[0, 1, 0]$, and $[0, 0, 1]$ [Exercise 3(b)].

Since every line has an equation, by duality every point also should have an equation. Take lines $[1, 2, 3]$ and $[2, 4, 1]$. The equations for these lines are

$$\begin{aligned} x_1 + 2x_2 + 3x_3 &= 0, \\ 2x_1 + 4x_2 + x_3 &= 0. \end{aligned}$$

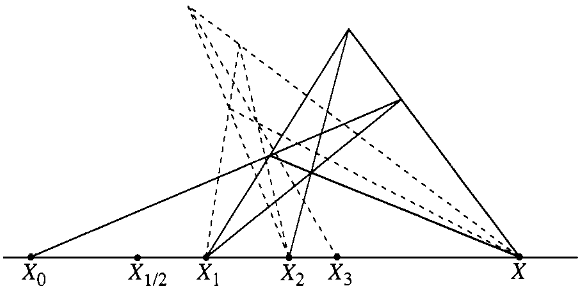

Figure 14.12 The points on a line form a harmonic net.

The solution to this linear system of equations is

$$x_1 = -2k, x_2 = k, \text{ and } x_3 = 0.$$

Therefore, the point of intersection can be taken to be $(2, -1, 0)$, and its equation is

$$2a_1 - a_2 = 0.$$

Any line $[a_1, a_2, a_3]$ that satisfies this equation will contain the point $(-2k, k, 0)$, provided that $k \neq 0$.

We may then combine these two concepts in the next definition.

■ DEFINITION 14.4.1

(x_1, x_2, x_3) is **incident** with $[a_1, a_2, a_3]$ or $[a_1, a_2, a_3]$ **contains** (x_1, x_2, x_3) if and only if

$$a_1x_1 + a_2x_2 + a_3x_3 = 0.$$

The definition makes clear why the ordered triple $(0, 0, 0)$ is excluded from our system of homogenous coordinates. Because $(0, 0, 0)$ satisfies the equation

$$a_1x_1 + a_2x_2 + a_3x_3 = 0$$

for all real numbers a_1, a_2, and a_3, the point that $(0, 0, 0)$ represents would be incident with every line. This is impossible in the projective plane (Exercise 1).

Incidence Results

Let $\mathcal{P} = \{P_1, P_2, \ldots, P_n\}$ be a set of points written using homogeneous coordinates. We define the set $\mathcal{P}$ to be **linearly independent** if it is linearly independent when viewed as a set of vectors. If $\mathcal{P}$ is not linearly independent, it is **linearly dependent**. Since $(x_1, x_2, \ldots, x_n)$ and $(kx_1, kx_2, \ldots, kx_n)$ with $k \neq 0$ represent the same point, two points in homogeneous coordinates are the same point if and only if they form a linearly dependent set. For three points, we have the following.

■ THEOREM 14.4.2

The set of points $\{(x_1, x_2, x_3), (y_1, y_2, y_3), (z_1, z_2, z_3)\}$ written in homogeneous coordinates is linearly dependent if and only if the points are collinear.

PROOF

Suppose that the three points are collinear. This means that there exists a line $[a_1, a_2, a_3]$ that is a solution to the equations for each of the three points:

$$\begin{array}{ccccccc} x_1a_1 & + & x_2a_2 & + & x_3a_3 & = & 0, \\ y_1a_1 & + & y_2a_2 & + & y_3a_3 & = & 0, \\ z_1a_1 & + & z_2a_2 & + & z_3a_3 & = & 0. \end{array}$$

The solution must be nontrivial in order for it to be a line, since $[0, 0, 0]$ does not represent a line. This can happen only if

$$\{(x_1, x_2, x_3), (y_1, y_2, y_3), (z_1, z_2, z_3)\}$$

is linearly dependent. Since these steps are reversible, we have proven the theorem. ■

A set of three vectors in $\mathbb{R}^3$ is linearly dependent if and only if the determinant of the matrix formed by the vectors of the set is zero.

■ COROLLARY 14.4.3

If (x_1, x_2, x_3), (y_1, y_2, y_3), (z_1, z_2, z_3) are in homogeneous coordinates,

$$\begin{vmatrix} x_1 & x_2 & x_3 \\ y_1 & y_2 & y_3 \\ z_1 & z_2 & z_3 \end{vmatrix} = 0$$

if and only if the points are collinear.

Theorem 14.4.2 and its corollary also hold for lines in the projective plane, by the principle of duality.

Equivalence Classes

Let $\sim$ be an equivalence relation on $\mathcal{A}$ (page 51). If $a \in \mathcal{A}$, the **equivalence class** of a is defined as the set

$$[a] = \{x \in \mathcal{A} : x \sim a\}.$$

The set of all equivalence classes,

$$\mathcal{A}/\sim\, = \{[a] : a \in \mathcal{A}\},$$

is called a **quotient set**, and we read $\mathcal{A}/\sim$ as "A modulo tilde." It is always the case that

$$\mathcal{A} = \bigcup_{a \in \mathcal{A}} [a].$$

The equivalence relation associates elements of the set that are considered the same type of element with respect to the equivalence relation. This has the effect of dividing the set up into cells that do not overlap, yet exhaust the entire set.

■ DEFINITION 14.4.4

Let $\mathcal{A} \neq \varnothing$ be a set and $\mathcal{P}$ be a set of subsets of $\mathcal{A}$. The set $\mathcal{P}$ is a **partition** of $\mathcal{A}$ if and only if

- $\bigcup \mathcal{P} = \mathcal{A}$.
- For all $\mathcal{B}, \mathcal{C} \in \mathcal{P}$, either $\mathcal{B} = \mathcal{C}$ or $\mathcal{B} \cap \mathcal{C} = \varnothing$.

The second condition of the definition means that $\mathscr{P}$ is **pairwise disjoint**. To illustrate this definition, let $\mathscr{A} = \{1, 2, 3, 4, 5, 6, 7\}$ and define $\mathscr{A}_1 = \{1, 2, 5\}$, $\mathscr{A}_2 = \{3\}$, and $\mathscr{A}_3 = \{4, 6, 7\}$. The family $\mathscr{P} = \{\mathscr{A}_1, \mathscr{A}_2, \mathscr{A}_3\}$ is pairwise disjoint, and $\mathscr{A} = \mathscr{A}_1 \cup \mathscr{A}_2 \cup \mathscr{A}_3$. Hence, $\mathscr{P}$ is a partition of $\mathscr{A}$. Similarly, the quotient set of an arbitrary set under an equivalence relation will be a partition for the set.

■ THEOREM 14.4.5

If $\sim$ is an equivalence relation on $\mathscr{A}$, then $\mathscr{A}/{\sim}$ is a partition of $\mathscr{A}$.

PROOF

Take a set $\mathscr{A}$ with an equivalence relation $\sim$. We first prove that $\bigcup(\mathscr{A}/{\sim}) = \mathscr{A}$. Suppose that $x \in \bigcup(\mathscr{A}/{\sim})$. This means that there exists $a \in \mathscr{A}$ such that $x \in [a]$. Since $[a] \subseteq \mathscr{A}$, x is an element of $\mathscr{A}$. To prove the converse, let $x \in \mathscr{A}$. Because $x \sim x$, x is an element of $[x]$. This implies that $x \in \bigcup(\mathscr{A}/{\sim})$ since $[x] \in \mathscr{A}/{\sim}$.

To show that $\mathscr{A}/{\sim}$ is pairwise disjoint, let $[a], [b] \in \mathscr{A}/{\sim}$ and assume that $[a] \cap [b] \neq \varnothing$. We conclude that there exists $y \in [a] \cap [b]$. In other words, $y \sim a$ and $y \sim b$. Now take $x \in [a]$. This means that $x \sim a$. Since $a \sim y$ by symmetry, $x \sim y$ and then $x \sim b$, both by transitivity. Thus, $x \in [b]$, which shows that $[a] \subseteq [b]$. Similarly, $[b] \subseteq [a]$. Therefore, $[a] = [b]$. ■

We now define an equivalence relation on a set of homogeneous coordinates and examine the resulting partition. Let

$$\mathscr{H} = \{(x_1, x_2, x_3) : x_1, x_2, x_3 \in \mathbb{R} \text{ but not all zero}\}.$$

Since all multiples of a given ordered triple identify the same point, define

$$(x_1, x_2, x_3) \sim (y_1, y_2, y_3)$$

if and only if there exists $k \in \mathbb{R}$ such that

$$\begin{aligned} x_1 &= ky_1, \\ x_2 &= ky_2, \\ x_3 &= ky_3. \end{aligned}$$

To show that this is an equivalence relation, take (x_1, x_2, x_3), (y_1, y_2, y_3), and (z_1, z_2, z_3) in $\mathscr{H}$.

- $(x_1, x_2, x_3) \sim (x_1, x_2, x_3)$ because $x_1 = 1x_1$, $x_2 = 1x_2$, and $x_3 = 1x_3$.
- Assume that $(x_1, x_2, x_3) \sim (y_1, y_2, y_3)$. From this we conclude that there exists $k \in \mathbb{R}$ such that $x_1 = ky_1$, $x_2 = ky_2$, and $x_3 = ky_3$. Since not all of the coordinates are zero, k must be nonzero. Therefore,

  $$y_1 = (1/k)x_1,\ y_2 = (1/k)x_2, \text{ and } y_3 = (1/k)x_3,$$

  which means that $(y_1, y_2, y_3) \sim (x_1, x_2, x_3)$

- Let $(x_1, x_2, x_3) \sim (y_1, y_2, y_3)$ and $(y_1, y_2, y_3) \sim (z_1, z_2, z_3)$. Then there exists $j, k \in \mathbb{R}$ so that

  $$x_1 = jy_1, x_2 = jy_2, \text{and } x_3 = jy_3$$

  and

  $$y_1 = kz_1, y_2 = kz_2, \text{and } y_3 = kz_3.$$

  Hence,

  $$x_1 = (jk)z_1, x_2 = (jk)z_2, \text{and } x_3 = (jk)z_3.$$

  Therefore, $(x_1, x_2, x_3) \sim (z_1, z_2, z_3)$.

Since $\sim$ is an equivalence relation on $\mathcal{H}$, the quotient set

$$\mathbb{P}^2 = \mathcal{H}/\sim$$

is a partition of $\mathcal{H}$. If we take $(x_1, x_2, x_3) \in \mathcal{H}$, the points in $\mathcal{H}$ that are equivalent to it are exactly those ordered triples that are nonzero multiples of (x_1, x_2, x_3). We conclude that

$$[(x_1, x_2, x_3)] = \{(kx_1, kx_2, kx_3) : k \neq 0\}.$$

Although there is not a unique ordered triple for every point in the projective plane, there is a unique equivalence class. When we work with these classes, we typically choose a particular element of the class, called a **representative**, and label the point with it. The quotient set $\mathbb{P}^2$ is called the **real projective plane**. It is left to Exercise 2 to confirm that $\mathbb{P}^2$ satisfies the postulates of projective geometry.

Of course, everything just written about points holds also for lines, so we have developed a complete system to label the objects in a projective plane. Although homogeneous coordinates were created independently by several mathematicians, including August Möbius, the full system is due to the German mathematician Julius Plücker. He was born in Elberfeld in 1801 and lived for 67 years. He studied at various universities throughout Europe, earning his doctorate from the University of Marburg in 1824. His mathematical specialty was analytic geometry, which he then applied to the projective plane. Since most methods in projective geometry at the time were synthetic, as appears to be the nature of the two camps, controversy again arose over which of the two methods was best. Plücker sided with the analysts, a decision which at one point cost him a residency position at Berlin. Despite the controversy, Plücker became a top German mathematician with a reputation for elegant work. His other interests included physics, on which he had a lasting correspondence with Michael Faraday (Burau and Schoenberg 1970, 44, 46; Boyer and Merzbach 1991, 540–543).

Collineations

The functions that we have examined so far both synthetically and analytically in a projective plane have been functions between ranges (e.g., central perspectivities) or between pencils (e.g., axial perspectivities in Exercise 6 of Section 14.3). We now want to define a function whose domain is an entire projective plane but still resembles the other functions. We will do our work on $\mathbb{P}^2$, and the function will be a collineation (Definition 14.1.5).

Suppose that $\phi : \mathbb{P}^2 \longrightarrow \mathbb{P}^2$ is a collineation and write

$$\begin{aligned}\phi(1, 0, 0) &= (x_1, y_1, z_1),\\ \phi(0, 1, 0) &= (x_2, y_2, z_2),\\ \phi(0, 0, 1) &= (x_3, y_3, z_3),\\ \phi(1, 1, 1) &= (x_4, y_4, z_4).\end{aligned}$$

This function has the property that it maps all points on a line to all of the points of another line, so ϕ must be a linear transformation. Therefore, there exists a 3×3 matrix A such that

$$\phi(X) = AX,$$

where X is a point from $\mathbb{P}^2$. Since ϕ is a one-to-one function, the determinant of A is not equal to zero.

As an example, define $\phi : \mathbb{P}^2 \longrightarrow \mathbb{P}^2$ by

$$\begin{aligned}\phi(1, 0, 0) &= (1, -2, 3),\\ \phi(0, 1, 0) &= (5, 6, 5),\\ \phi(0, 0, 1) &= (1, 0, 4),\\ \phi(1, 1, 1) &= (3, 2, 1).\end{aligned}$$

Observe that

$$\phi(1, 1, 1) = \phi(1, 0, 0) + \frac{2}{3}\phi(0, 1, 0) - \frac{4}{3}\phi(0, 0, 1)$$

or

$$3\phi(1, 1, 1) = 3\phi(1, 0, 0) + 2\phi(0, 1, 0) - 4\phi(0, 0, 1).$$

Therefore,

$$3\begin{bmatrix} x_1' \\ x_2' \\ x_3' \end{bmatrix} = \begin{bmatrix} 3 & 10 & -4 \\ -6 & 12 & 0 \\ 9 & 10 & -16 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix},$$

which gives rise to this system of linear equations:

$$\begin{aligned} 3x_1' &= 3x_1 + 10x_2 - 4x_3,\\ 3x_2' &= -6x_1 + 12x_2,\\ 3x_3' &= 9x_1 + 10x_2 - 16x_3. \end{aligned}$$

We see that we can generalize this to the next proposition.

■ THEOREM 14.4.6

The collineation $\phi : \mathbb{P}^2 \to \mathbb{P}^2$, where $\phi(x_1, x_2, x_3) = (x_1', x_2', x_3')$, is defined by the equations

$$\begin{aligned} kx_1' &= a_{11}x_1 + a_{12}x_2 + a_{13}x_3, \\ kx_2' &= a_{21}x_1 + a_{22}x_2 + a_{23}x_3, \\ kx_3' &= a_{31}x_1 + a_{32}x_2 + a_{33}x_3 \end{aligned}$$

such that $k \neq 0$ and

$$\begin{vmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{vmatrix} \neq 0.$$

Finally, let ϕ be a collineation on $\mathbb{P}^2$. Observe that if we take lines l and m in $\mathbb{P}^2$, their images $\phi[l]$ and $\phi[m]$ are also lines in $\mathbb{P}^2$. Let O be a point not on l or m, so $\phi(O)$ is not on $\phi[l]$ or on $\phi[m]$. If A is on m and B on m such that A, O, and B are collinear, $\phi(A)$ is on $\phi[l]$, $\phi(B)$ is on $\phi[m]$, and $\phi(A)$, $\phi(O)$, and $\phi(B)$ are collinear. All of this follows because ϕ is a collineation. Therefore, if

$$T : l \to m$$

is a central perspectivity,

$$\phi \circ T \circ \phi^{-1} : \phi[l] \to \phi[m]$$

is a central perspectivity. It is then reasonable to say that perspectivities are preserved under collineations. Similarly, since a projectivity is the composition of perspectivities, we can also say that projectivities are preserved under collineations. For this reason, a collineation on $\mathbb{P}^2$ is usually called a **projective collineation**.

Exercises

1. Explain why it is not possible that a point exists in the projective plane that is on every line.

2. Confirm that $\mathbb{P}^2$ is a projective plane.

3. Using Figure 14.11:
   (a) Find the coordinates of points A, B, and C.
   (b) Show that the coordinates for $\overline{E_2E_3}$, $\overline{E_1E_3}$, and $\overline{E_1E_2}$ are, respectively, $[1, 0, 0]$, $[0, 1, 0]$, and $[0, 0, 1]$.
   (c) Find the coordinates for $\overline{AE_1}$, $\overline{BE_2}$, and $\overline{CE_3}$.
   (d) Find two more points between B and E_1 and two more between E_3 and B.
   (e) Find the intersection of $\overline{AC}$ and $\overline{BE_2}$.

4. Find the homogeneous coordinates for the line between $(3, 0, 6)$ and $(0, 4, 1)$.

5. Find the equation for the intersection of $[6, -4, 2]$ and $[1, 1, 8]$.

6. Determine whether the following points are collinear.
   (a) $(3, 0, 0), (3, -4, 0), (1, 1, 1)$
   (b) $(9, 8, -5), (2, -8, 9), (2, -6, 9), (2, -8, 4)$

7. Find ordered triples (a_1, a_2, a_3), (b_1, b_2, b_3), and (c_1, c_2, c_3) in homogeneous coordinates that are multiples of the given points and such that

$$(a_1, a_2, a_3) = (b_1, b_2, b_3) + (c_1, c_2, c_3).$$

   (a) $(0, 0, 5), (1, 1, 1), (7, 7, 0)$
   (b) $(-2, 0, 1), (1, -1, 2), (4, -2, 3)$
   (c) $(1, 2, 3), (0, 1, 2), (-1, 0, 1)$

8. Using Figure 14.11:
   (a) Find the lines of the complete quadrangle with vertices E, C, E_1, and B.
   (b) Confirm that the diagonal points are not collinear.
   (c) Generalize this to show that the diagonal points of any complete quadrangle are not collinear.

9. For all nonzero real numbers a and b, let $a \sim b$ if and only if $ab > 0$.
   (a) Show that $\sim$ is an equivalence relation on $\mathbb{R}\backslash\{0\}$.
   (b) Find the equivalence classes $[1]$ and $[-3]$.

10. For all $a, b \in \mathbb{Z}$, let $a \sim b$ if and only if $|a| = |b|$.
   (a) Prove that $\sim$ is an equivalence relation on $\mathbb{Z}$.
   (b) Describe $\mathbb{Z}/\sim$.

11. For all $(a, b), (c, d) \in \mathbb{Z}\backslash\{0\} \times \mathbb{Z}\backslash\{0\}$, define $(a, b) \sim (c, d)$ if and only if $ad = bc$.
   (a) Show that $\sim$ is an equivalence relation on $\mathbb{Z}\backslash\{0\} \times \mathbb{Z}\backslash\{0\}$.
   (b) What is the equivalence class of $(1, 2)$?
   (c) Describe $(\mathbb{Z}\backslash\{0\} \times \mathbb{Z}\backslash\{0\})/\sim$.

12. Prove that the following are partitions of $\mathbb{R}^2$.
   (a) $\mathscr{E} = \{\{(a, b)\} : a, b \in \mathbb{R}\}$.
   (b) $\mathscr{F} = \{V_r : r \in \mathbb{R}\}$, where $V_r = \{(r, y) : y \in \mathbb{R}\}$ for all real numbers r.
   (c) $\mathscr{H} = \{H_n : n \in \mathbb{Z}\}$, where $H_n = \{\mathbb{R} \times (n, n+1] : n \in \mathbb{Z}\}$ for all $n \in \mathbb{Z}$.

13. Is $\{[n, n+1] \times (n, n+1) : n \in \mathbb{Z}\}$ a partition of $\mathbb{R}^2$? Explain.

14. Define the collineation $\phi : \mathbb{P}^2 \to \mathbb{P}^2$ by $\phi(X) = AX$, where

$$A = \begin{bmatrix} 1 & 1 & 1 \\ 0 & 2 & 1 \\ 1 & 0 & 1 \end{bmatrix}.$$

   (a) Find $\phi(1, 2, 3)$ and $\phi[4, 5, 6]$.
   (b) Write the image of the unit point as a linear combination of the images of the vertices of the reference triangle.

(c) Find $\phi^{-1}(4, 0, 1)$.

(d) Find the intersection of $\phi^{-1}[-1, 4, 6]$ and $\phi^{-1}[0, 0, 2]$.

15. Let $\psi : \mathbb{P}^2 \to \mathbb{P}^2$ be a collineation such that $\psi(1, 0, 0) = (2, -2, 8)$, $\psi(0, 1, 0) = (2, 5, 1)$, $\psi(0, 0, 1) = (2, 2, 4)$, and $\psi(1, 1, 1) = (0, 1, -1)$.

(a) Find the matrix for ψ.

(b) Write ψ as a system of linear equations.

16. Let $\phi : \mathbb{P}^2 \to \mathbb{P}^2$ be a collineation such that $\phi(2, 1, 1) = (3, 1, -5)$, $\phi(2, -1, 1) = (1, 1, -3)$, $\phi(1, 2, 1) = (-1, 0, 2)$, $\phi(5, 2, 3) = (6, 4, -12)$.

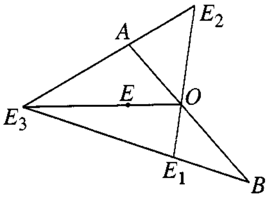
(a) Find the matrix for $\psi_1 : \mathbb{P}^2 \to \mathbb{P}^2$ such that $\psi(1, 0, 0) = (2, 1, 1)$, $\psi(0, 1, 0) = (2, -1, 1)$, $\psi(0, 0, 1) = (1, 2, 1)$, $\psi(1, 1, 1) = (5, 2, 3)$.

(b) Find the matrix for $\psi_2 : \mathbb{P}^2 \to \mathbb{P}^2$ such that we have $\psi(1, 0, 0) = (3, 1, -5)$, $\psi(0, 1, 0) = (1, 1, -3)$, $\psi(0, 0, 1) = (-1, 0, 2)$, and $\psi(1, 1, 1) = (6, 4, -12)$.

(c) Use the matrices for ψ_1 and ψ_2 to find the matrix for ϕ.

(d) Write ϕ as a system of linear equations.

17. Let $E_1 = (1, 0, 0)$, $E_2 = (0, 1, 0)$, $E_3 = (0, 0, 1)$, and $E = (1, 1, 1)$. The point O at the intersection of $\overline{EE_3}$ and $\overline{E_1E_2}$ defines a central perspectivity between $\overline{E_1E_3}$ and $\overline{E_2E_3}$. After finding the homogeneous coordinates for A and B (Exercise 3), find an equation relating the homogeneous coordinates of A with those of B that must be satisfied in order for $A \overset{O}{\barwedge} B$ through O.



CHAPTER 15

FELIX KLEIN

After lecturing at Göttingen for a year, Klein joined the faculty at the University of Erlangen in 1872. The public lecture that earned him this position he titled *A Comparative Review of Recent Researches in Geometry* (Klein 1893). In it he introduced a new means of classifying geometries that became known as the **Erlangen Program**. It characterized a geometry based on the properties that were preserved under certain sets of functions. This is similar to what Poncelet had done in his *Traite*. There Poncelet looked for properties that were preserved under projectivities. One such property was that of being a harmonic set. Klein's scheme would begin with the projective transformations, and then by placing restrictions on these functions, find other collections that would yield their own types of invariants on other geometries. Each of the sets of functions were required to satisfy certain conditions, making them into what is called a group. Klein had learned of this algebra concept from Camille Jordan when he traveled to Paris with Sophus Lie (Yaglom 1988, 128–129; Burau and Schoenberg 1970, 396–397; Wussing 1984, 27).

Lie was from Norway and was seven years older than Klein. Lie was an interesting combination of outdoorsman and overall success in all of the academic subjects. When it came time for college, he had his choice of fields. Lie's father was a Lutheran pastor, so Lie considered studying theology, but decided instead on mathematics and

Revolutions of Geometry. By Michael O'Leary

the sciences at Christiania University. It was there where he read the works of Poncelet and Plücker. These two mathematicians had a lasting impact on Lie, and their work would inspire Lie's long research program on geometric transformations. Lie went to Berlin in 1870 to continue his mathematical education. It was in Berlin where Klein and Lie first met. They would become lifelong friends and work on many projects together (Yaglom 1988, 22; Burau and Schoenberg 1970, 396).

One of their first joint undertakings was to go to Paris and learn about current French mathematics. They arrived in late 1870. In Paris Klein and Lie studied geometry and learned about group theory. While there it was their intention to meet Camille Jordan, who had recently published *Commentaire sur le mémorie de Galois* in 1865 and *Commentaire sur Galois* in 1869. These were expositions on the work of Evariste Galois, a gifted mathematician who began a study of the subject when he was 15, developed an approach to deal with equations solvable by radicals, spent time in jail as a political prisoner, and was killed in a dual at the age of 21. Klein was particularly impressed with Jordan's *Traité des substitutions et des équations algébriques*. Inspired by what they learned, Klein and Lie coauthored two papers, one published in June 1870 and the other in March 1871. These would become the preliminary work for Klein's Erlangen lecture (Wussing 1984, 135–136, 180–184; Yaglom 1988, 22; Kline 1972, 755–756).

Klein and Lie left Berlin in July 1870, at the start of the Franco-Prussian War. Being German, Klein needed to leave the country. When he arrived home, he planned to join the Prussian army, but he caught typhus. When he recovered, Klein returned to Göttingen. All the while Lie remained in France to hike the French countryside, see the Alps, and then to see Italy. Although it was only for a month, he did spend some time in a French prison under suspicion of spying for Germany (Wussing 1984, 179; Yaglom 1988, 24, 27).

15.1 GROUP THEORY

So what is a group? Start with the set of integers $\mathbb{Z}$. If we add any two integers together, the result will be an integer, and this result will be unique to the original two integers. For example, the sum of 5 and 3 is 8 and always will be 8. The same thing goes for subtraction and multiplication. Division is a problem, however. We cannot divide by zero, and an integer divided by an integer is not guaranteed to be an integer. On the set of integers, addition, subtraction, and multiplication are examples of binary operations, whereas division is not.

■ **DEFINITION 15.1.1**

A **binary operation** on a set $\mathcal{S}$ is a function $* : \mathcal{S} \times \mathcal{S} \to \mathcal{S}$.

Since a binary operation is a generalization of the more concrete operations of addition and multiplication, we write

$$a * b$$

instead of $*(a, b)$. The following are examples of binary operations.

- $a * b = |ab|$ on $\mathbb{R}$.
- Addition, subtraction, and multiplication on $\mathbb{R}$.
- Division on $(-\infty, 0) \cup (0, \infty)$.
- $a * b = \sqrt{ab}$ on $[0, \infty)$.

To show that a rule on a set $\mathcal{S}$ is a binary operation, we must show that is satisfies two properties. First, it must be well defined as a function, and second, it must be true that $a * b \in \mathcal{S}$ for all $a, b \in \mathcal{S}$. When this second condition is satisfied, we say that $\mathcal{S}$ is **closed under** $*$.

Consider the following example. Denoting the set of positive integers by $\mathbb{Z}^+$, for all $n \in \mathbb{Z}^+$ and $a \in \mathbb{Z}$, define

$$[a]_n = \{a + kn : k \in \mathbb{Z}\}.$$

This is called the **congruence class** of a **modulo** n (see Exercise 12 from Section 2.3 and also page 511). For instance,

$$\begin{aligned}
[0]_4 &= \{\ldots, -4, 0, 4, 8, \ldots\},\\
[1]_4 &= \{\ldots, -3, 1, 5, 9, \ldots\},\\
[2]_4 &= \{\ldots, -2, 2, 6, 10, \ldots\},\\
[3]_4 &= \{\ldots, -1, 3, 7, 11, \ldots\}.
\end{aligned}$$

The collection cycles because $[4]_4 = [0]_4$. We now define

$$\mathbb{Z}_n = \{[a]_n : a \in \mathbb{Z}\},$$

and on this set specify $+$ by

$$[a]_n + [b]_n = [a + b]_n.$$

Be careful to note that the symbol $+$ is being used in two ways. The $+$ on the left is the new definition, but the $+$ on the right is standard addition.

We first show that this addition is well defined. This is particularly important to prove this in this case since each congruence class can be represented using infinitely many different integers. Take $[a]_n, [b]_n, [a']_n, [b']_n \in \mathbb{Z}_n$ and suppose that

$$[a]_n = [a']_n \text{ and } [b]_n = [b']_n.$$

This does *not* mean that $a = a'$ and $b = b'$. Instead, we conclude that

$$a = a' + jn \text{ and } b = b' + kn$$

for some $j, k \in \mathbb{Z}$. To show that the result of operating these two equal pairs of elements together yields the same answer, we must show that

$$[a + b]_n = [a' + b']_n.$$

To do this, let $x \in [a+b]_n$. This means that $x = a + b + ln$ for some $l \in \mathbb{Z}$. Therefore,

$$x = a' + jn + b' + kn + ln = a' + b' + (j + k + l)n,$$

from which follows that $x \in [a' + b']_n$ because $j + k + l \in \mathbb{Z}$. Hence,

$$[a + b]_n \subseteq [a' + b']_n.$$

The other inclusion follows similarly.

It is a simple matter to see that $\mathbb{Z}_n$ is closed under $+$. Let $[a]_n$, $[b]_n \in \mathbb{Z}_n$. This means that a and b are integers. Since we know that $\mathbb{Z}$ is closed under standard addition, $a + b \in \mathbb{Z}$. Therefore, $[a]_n + [b]_n = [a + b]_n \in \mathbb{Z}_n$.

Groups

Now consider the properties of addition as viewed as a binary operation on the set of integers. We know that addition is commutative and associative (page 32). There is a particular element of $\mathbb{Z}$ that is denoted by 0 that has the property

$$\text{for all } a \in \mathbb{Z}, 0 + a = a + 0 = a.$$

The number 0 is the additive identity of $\mathbb{Z}$. Finally, every integer a has an additive inverse. This inverse is denoted by $-a$ and has the property that

$$a + (-a) = (-a) + a = 0.$$

In other words, an integer added to its inverse yields the identity. Ignoring the commutative condition for the moment, we make our definition.

■ **DEFINITION 15.1.2**

Let $\mathscr{G}$ be a set and $*$ a binary operation with the following properties:

- $a * (b * c) = (a * b) * c$ for all $a, b, c \in \mathscr{G}$.
- There exists $e \in \mathscr{G}$ such that $e * a = a * e = a$ for all $a \in \mathscr{G}$. The element e is called the **identity** of $\mathscr{G}$.
- For all $a \in \mathscr{G}$, there exists $a' \in \mathscr{G}$ such that $a * a' = a' * a = e$. The element a' is called the **inverse** of a' in $\mathscr{G}$.

The pair $(\mathscr{G}, *)$ is called a **group**. When the group's binary operation is clear from context, the set $\mathscr{G}$ can be referred to as the group.

The term *group* was first used by Galois (Wussing 1984, 17). A group with a commutative binary operation (that $a * b = b * a$ for all a and b in the group) is known as an **abelian group.** It is named after the Norwegian mathematician Niels Henrik Abel.

b	b	c	e	a
c	c	b	a	e

(b) Klein-4 group

Figure 15.1 The groups of order four.

The pairs $(\mathbb{Z}^+, +)$, $(\mathbb{Z}, \cdot)$, and $(\mathbb{R}, \cdot)$ are not groups, but $(\mathbb{Z}, +)$, $(\mathbb{Q}, +)$, $(\mathbb{R}, +)$, $(\mathbb{Q}\backslash\{0\}, \cdot)$, and $(\mathbb{R}\backslash\{0\}, \cdot)$ are. These are examples of infinite groups. When the group's set is finite, we use the term **order** to refer to its cardinality. The group $(\{e\}, *)$, where $*$ is any binary operation, is the only group of order 1. This means that any other group with one element, such as $(\{0\}, +)$ or $(\{1\}, \cdot)$, has the same structure as $(\{e\}, *)$. We say that these three groups are **isomorphic**. Any group of order 2 will be isomorphic to $\mathbb{Z}_2$, and any group of order 3 will be isomorphic to $\mathbb{Z}_3$. There are essentially two groups of order 4: those that are isomorphic to $\mathbb{Z}_4$ and those that are isomorphic to the **Klein-4** group. Their tables are given in Figure 15.1.

All of the examples given so far have been abelian. Define $\mathrm{GL}(n, \mathbb{R})$ to be the pair consisting of the set of all $n \times n$ invertible matrices with real entries and matrix multiplication. This is called the **general linear group**. We know that matrix multiplication is associative, that its identity is the identity matrix, which is invertible, and that every matrix in the set has an inverse by definition. However, we know that even for invertible matrices, multiplication is not commutative. Therefore, $\mathrm{GL}(n, \mathbb{R})$ is a nonabelian group.

The group definition states only that in a group there is an identity and there are inverses. Based on what we know about the integers, we should be able to prove more about these elements.

■ THEOREM 15.1.3

In a group there is exactly one identity and every element has a unique inverse.

PROOF

The uniqueness of the identity is left to Exercise 8. To show the uniqueness of inverses, let $\mathcal{G}$ be a group, and take $a \in \mathcal{G}$. Suppose that both a' and a'' are inverses of a in $\mathcal{G}$. Then

$$a' = a' * e = a' * (a * a'') = (a' * a) * a'' = e * a'' = a''. \blacksquare$$

The purpose behind a group is that it is the most basic algebraic structure in which simple equations can be solved. For example, to solve $x + 4 = 10$, we need the additive inverse of 4 to add to both sides of the equation. After this we need to be able to regroup so that we may add the inverse to 4 to obtain the identity. As a consequence of these three properties, we will discover that the solution found is the unique one for the equation. All of this is summarized in the next theorem.

■ **THEOREM 15.1.4 [Cancellation Law]**

Let $\mathcal{G}$ be a group and a' be the inverse of a. For all a, $b \in \mathcal{G}$:

- The unique solution to $a * x = b$ is $x = a' * b$.
- The unique solution to $x * a = b$ is $x = b * a'$.

PROOF

That $a' * b$ is a solution of $a * x = b$ simply requires a check:

$$a * (a' * b) = (a * a') * b = e * b = b.$$

To see that the solution is unique, suppose that both u and v are solutions to the equation. Again we calculate:

$$\begin{aligned} a * u &= a * v, \\ a' * (a * u) &= a' * (a * v), \\ (a' * a) * u &= (a' * a) * v, \\ e * u &= e * v, \\ u &= v. \end{aligned}$$

Therefore, $a' * b$ is the only solution to $a * x = b$. That the other equation has a unique solution as indicated is proven similarly. ■

Subgroups

Let a be an element of a group $\mathcal{G}$. For all positive integers n, define a^n to be the result of operating a with itself n times. That is,

$$a^1 = a,\ a^2 = a * a,\ a^3 = a * a * a,\ \ldots$$

and

$$a^m * a^n = a^{m+n}.$$

Further define $a^0 = e$ and a^{-1} to be the inverse of a. With this notation we observe that

$$(a * b)^{-1} = b^{-1} * a^{-1}$$

and

$$a^{-n} = (a^n)^{-1} = (a^{-1})^n.$$

We then gather all of these elements into a set,

$$\langle a \rangle = \{a^n : n \in \mathbb{Z}\},$$

and define the following.

■ DEFINITION 15.1.5

A group $\mathcal{G}$ is **cyclic** if there exists $a \in \mathcal{G}$ such that $\mathcal{G} = \langle a \rangle$. The element a is called a **generator** of $\mathcal{G}$.

For example, $(\mathbb{Z}, +)$ is a cyclic group. Both 1 and -1 are generators. However, $\mathbb{Q}$ and $\mathbb{R}$ are not cyclic groups under addition. As for finite groups, each $\mathbb{Z}_n$ is cyclic, generated by $[1]_n$, but the Klein-4 group is not cyclic because $a^2 = e$ for all a in the group.

An element a of a group may not generate the entire group, but since $e \in \langle a \rangle$ and both a^n and a^{-n} are elements of $\langle a \rangle$, the set generated by a is a group using the operation from $\mathcal{G}$.

■ DEFINITION 15.1.6

Let $\mathcal{G}$ be a group with binary operation $*$ and $\mathcal{H} \subseteq \mathcal{G}$. We say that $\mathcal{H}$ is a **subgroup** of $\mathcal{G}$ if $(\mathcal{H}, *)$ is a group.

Every group with at least two elements has at least two subgroups, itself (the **improper subgroup**) and $\{e\}$ (the **trivial subgroup**). A group that has as most these two subgroups is called **simple**. For example, $\mathbb{Z}_2$ and $\mathbb{Z}_3$ are simple groups, but $\mathbb{Z}_4$ is not. It has $\{[0]_4, [2]_4\}$ as a subgroup. Other examples of nonsimple groups are $(\mathbb{R}, +)$ because $(\mathbb{Z}, +)$ is one of its subgroups and $(\langle 2 \rangle, +)$ because $(\langle 6 \rangle, +)$ is one of its subgroups.

Since every element of a cyclic group can be written as a generator to a power, we can write equations for each of the elements of a cyclic group. This simplifies our work when we deal with these types of groups. The cyclic groups then pass this property to their subgroups. To prove this we need the following proposition, known as the **Division Algorithm**, that was presupposed by Euclid in his method for finding the greatest common divisor of two positive integers (Euclid 1925, VII.2). We omit the proof of the Division Algorithm, but it can be found in any introductory number theory text such as Rosen (1993, 37–38).

■ THEOREM 15.1.7 [Division Algorithm]

If $m > n > 0$ are integers, there exists unique integers q and r such that $0 \leqslant r < n$ and

$$m = nq + r.$$

The integer q is called the **quotient** and r is called the **remainder**. We need the theorem to prove the following.

■ THEOREM 15.1.8

A subgroup of a cyclic group is cyclic.

PROOF

Let $\mathcal{G}$ be a cyclic group with generator a. Let $\mathcal{H}$ be a subgroup of $\mathcal{G}$. If $\mathcal{H} = \{e\}$, the subgroup is cyclic with generator e. So suppose that $\mathcal{H}$ is not the trivial subgroup. Because $\mathcal{G}$ is cyclic, there exists a minimum positive integer n such that $a^n \in \mathcal{H}$. Suppose that this element is not a generator of $\mathcal{H}$. This means that there exists an integer $m > n$ such that $a^m \in \mathcal{H}$ but $a^m \notin \langle a^n \rangle$. This combined with the Division Algorithm yields unique integers q and r such that $m = nq + r$ and $0 < r < n$. Therefore,

$$a^m = a^{nq+r} = a^{nq} * a^r,$$

and from this we conclude that

$$a^r = a^m * a^{-nq}.$$

Since both a^m and a^{-nq} are elements of $\mathcal{H}$, a^r is an element of $\mathcal{H}$. This contradicts the minimality of n because $r < n$. Thus, a^n is a generator of $\mathcal{H}$. ■

To show that a set is a subgroup of a group, we do not need to show directly that the set satisfies the three group properties. We may check a different set of conditions instead.

■ THEOREM 15.1.9

Let $(\mathcal{G}, *)$ be a group with identity e. A subset $\mathcal{H}$ of $\mathcal{G}$ is a subgroup of $\mathcal{G}$ if and only if:

- $\mathcal{H}$ is closed under $*$.
- $e \in \mathcal{H}$.
- $a^{-1} \in \mathcal{H}$ for all $a \in \mathcal{H}$.

PROOF

Suppose that the three hypotheses of the theorem hold. We conclude the following:

- $*$ is a binary operation on $\mathcal{H}$ because $\mathcal{H}$ is closed under $*$.
- Since $*$ is associative on $\mathcal{G}$, it must be associative on $\mathcal{H}$.
- $e \in \mathcal{H}$, and every element of $\mathcal{H}$ has its inverse in $\mathcal{H}$.

Therefore, $(\mathcal{H}, *)$ is a group. Conversely, if $\mathcal{H}$ is a subgroup of $\mathcal{G}$, the three conditions clearly hold. ■

To illustrate the theorem, take a group $\mathcal{G}$ and a family of subgroups $\{\mathcal{H}_i : i \in I\}$. We claim that $\bigcap_{i \in I} \mathcal{H}_i$ is a subgroup of $\mathcal{G}$.

- Let $a, b \in \bigcap_{i \in I} \mathcal{H}_i$. This means that $a, b \in \mathcal{H}_i$ for all $i \in I$. Since each $\mathcal{H}_i$ is closed under the operation of $\mathcal{G}$, $a * b \in \mathcal{H}_i$ for all i. Hence,

$$a * b \in \bigcap_{i \in I} \mathcal{H}_i.$$

- Since e in each $\mathcal{H}_i$ for every $i \in I$, we must have $e \in \bigcap_{i \in I} \mathcal{H}_i$.
- Take $a \in \bigcap_{i \in I} \mathcal{H}_i$. Then because $a \in \mathcal{H}_i$ for all $i \in I$, we have $a^{-1} \in \mathcal{H}_i$, so $a^{-1} \in \bigcap_{i \in I} \mathcal{H}_i$.

We do not obtain the same result for union (Exercise 15).

Exercises

1. Which of the following are binary operations on the given sets?
   (a) Subtraction on $[0, \infty)$
   (b) Multiplication on $\mathbb{R}$
   (c) Division on $\mathbb{Z}^+$
   (d) $a * b = a^b$ on $\mathbb{Z}$
   (e) $a * b = \max\{a, b\}$ on $\mathbb{Z}$
   (f) $a * b = \sqrt{ab}$ on $\mathbb{R}$

2. What assumptions about $\mathbb{Z}$ must be made to show that $x * y = 2x - y$ is a binary operation on $\mathbb{Z}$?

3. Let $\mathcal{S}$ be a set and $P(\mathcal{S})$ the set of subsets of $\mathcal{S}$. The family of sets $P(\mathcal{S})$ is called the **power set** of $\mathcal{S}$.
   (a) Define $*$ such that for all $\mathcal{A}, \mathcal{B} \in \mathcal{S}$, $\mathcal{A} * \mathcal{B} = \mathcal{A} \cap \mathcal{B}$. Prove that $*$ is a binary operation on $\mathcal{S}$.
   (b) Is $(\mathcal{S}, *)$ a group? Explain.

4. Explain why $(\mathbb{Z}^+, +)$, $(\mathbb{Z}, \cdot)$, and $(\mathbb{R}, \cdot)$ are not groups.

5. Suppose that $*$ is defined by $x * y = x + y + 2$.
   (a) Identify the identity and the inverses for this group.
   (b) Prove that $(\mathbb{Z}, *)$ is a group.
   (c) Solve $8 * x = 10$ in $(\mathbb{Z}, *)$.

6. Let $\mathcal{F}$ be the set of **real-valued** functions. That is, each element of $\mathcal{F}$ is a function $f : \mathbb{R} \to \mathbb{R}$.
   (a) Prove that $(\mathcal{F}, +)$ is a group where

$$(f + g)(x) = f(x) + g(x).$$

   (b) Is $(\mathcal{F}, /)$ a group where $/$ is function division?
   (c) Is $(\mathcal{F}, \circ)$ a group where $\circ$ is composition of functions? Explain.

7. Let n be a positive integer and define

$$M_n = \left\{ \begin{bmatrix} a_{1,1} & a_{1,2} & \cdots & a_{1,n} \\ a_{2,1} & a_{2,2} & \cdots & a_{2,n} \\ \vdots & \vdots & & \vdots \\ a_{n,1} & a_{n,2} & \cdots & a_{n,n} \end{bmatrix} : a, b, c, d \in \mathbb{R} \right\}.$$

(a) Show that M_n under addition is a group.
(b) Solve the equation in M_2:

$$\begin{bmatrix} 1 & 4 \\ -3 & 0 \end{bmatrix} + \begin{bmatrix} a & b \\ c & d \end{bmatrix} = \begin{bmatrix} -3 & 8 \\ 0 & -6 \end{bmatrix}.$$

(c) Show that M_n under multiplication is not a group.

8. Prove that the identity of a group is unique.

9. Let $\mathcal{G}$ be a group. Define $\phi : \mathcal{G} \to \mathcal{G}$ by $\phi(a) = a^{-1}$. Prove that ϕ is a one-to-one correspondence.

10. Let $(\mathcal{G}, *)$ and $(\mathcal{G}', *')$ be two groups. Define the **Cartesian product** of $\mathcal{G}$ and $\mathcal{G}'$ as

$$\mathcal{G} \times \mathcal{G}' = \{(a, a') : a \in \mathcal{G} \text{ and } a' \in \mathcal{G}'\}.$$

Define $(a, a') \cdot (b, b') = (a * b, a' *' b')$.

(a) Confirm that $\cdot$ is a binary operation on $\mathcal{G} \times \mathcal{G}'$.
(b) Show that $(\mathcal{G} \times \mathcal{G}', \cdot)$ is a group. Prove that it is abelian if and only if both $\mathcal{G}$ and $\mathcal{G}'$ are abelian.

11. Let $\mathcal{G}$ be a group so that $(a * b)^2 = a^2 * b^2$ for all $a, b \in \mathcal{G}$. Show that $\mathcal{G}$ is abelian.

12. Identify all of the subgroups of the following groups.
(a) the Klein-4 group
(b) $\mathbb{Z}_5$
(c) $\mathbb{Z}_8$
(d) $\mathbb{Z}_2 \times \mathbb{Z}_3$
(e) $\mathbb{Z}_2 \times \mathbb{Z}_6$

13. Let $\mathcal{F}$ be the set of real-valued functions (Exercise 6). Show that

$$\{f \in \mathcal{F} : f(0) = 0\}$$

is a subgroup of $(\mathcal{F}, +)$.

14. Define $\mathcal{H} = \{A \in M_n : a_{1,1} + a_{2,2} + \cdots + a_{n,n} = 0\}$. Prove that $\mathcal{H}$ is a subgroup of $(M_n, +)$.

15. Let $\mathcal{G}$ be a group and $\{\mathcal{H}_i : i \in I\}$ a family of subgroups of $\mathcal{G}$.
(a) Give an example to show that $\bigcup_{i \in I} \mathcal{H}_i$ is not necessarily a subgroup of $\mathcal{G}$.
(b) Assume that for all $i, j \in I$, either $\mathcal{H}_i \subseteq \mathcal{H}_j$ or $\mathcal{H}_j \subseteq \mathcal{H}_i$. Show that $\bigcup_{i \in I} \mathcal{H}_i$ is a subgroup of $\mathcal{G}$.

16. Let $\mathcal{H}$ and $\mathcal{K}$ be two subgroups of an abelian group $\mathcal{G}$. Define

$$\mathcal{H}\mathcal{K} = \{a * b : a \in \mathcal{H} \text{ and } b \in \mathcal{K}\}.$$

Prove that $\mathcal{H}\mathcal{K}$ is a subgroup of $\mathcal{G}$. Is it abelian?

17. For any group $\mathscr{G}$, let $\mathscr{S} \subseteq \mathscr{G}$. Prove that

$$\mathscr{H} = \{a \in \mathscr{G} : a * b = b * a \text{ for all } b \in \mathscr{S}\}$$

is a subgroup of $\mathscr{G}$.

18. Let $s \in \mathscr{G}$. Define $\mathscr{G}_s = \{a \in \mathscr{G} : a * s = s\}$. Show that this set, called the **stabilizer** of s, is a subgroup of $\mathscr{G}$.

19. Let $\mathscr{H}$ and $\mathscr{H}'$ be subgroups of groups $\mathscr{G}$ and $\mathscr{G}'$, respectively. Show that $\mathscr{H} \times \mathscr{H}'$ is a subgroup of $\mathscr{G} \times \mathscr{G}'$ under the operation defined in Exercise 10.

20. Write four elements of each of the following cyclic subgroups.
   (a) $\langle 1/2 \rangle$ in $(\mathbb{Q}, +)$
   (b) $\langle 1/2 \rangle$ in $(\mathbb{R}\backslash\{0\}, \cdot)$
   (c) $\langle [3] \rangle$ in $\mathbb{Z}_8$
   (d) $\langle x^2 + 1 \rangle$ the group of real-valued functions under addition

21. Take a to be an element of a group with binary operation $*$. Let k be a positive integer. Prove that $\{a^{nk} : n \in \mathbb{Z}\}$ is a subgroup of $\langle a \rangle$.

22. Demonstrate that simple groups are cyclic.

15.2 TRANSFORMATION GROUPS

In this section we introduce the type of group that was central to Klein's Erlangen Program. We begin with an arbitrary set $\mathscr{S}$ and define a **transformation** of $\mathscr{S}$ to be a function $\phi : \mathscr{S} \to \mathscr{S}$ that is a one-to-one correspondence. Let Trans($\mathscr{S}$) be the set of all transformations of $\mathscr{S}$. We make four observations.

- If $\phi, \psi \in$ Trans($\mathscr{S}$), then $\phi \circ \psi \in$ Trans($\mathscr{S}$) since the composition of two one-to-one correspondences on $\mathscr{S}$ is a one-to-one correspondence on $\mathscr{S}$.
- Composition is associative, namely for all $\phi, \psi, \sigma \in$ Trans($\mathscr{S}$),
$$(\phi \circ \psi) \circ \sigma = \phi \circ (\psi \circ \sigma).$$
- The identity map is a one-to-one correspondence, so it is an element of Trans($\mathscr{S}$).
- If $\phi \in$ Trans($\mathscr{S}$), then $\phi^{-1} \in$ Trans($\mathscr{S}$) because the inverse of any one-to-one correspondence on $\mathscr{S}$ is a one-to-one correspondence on $\mathscr{S}$.

Therefore, (Trans($\mathscr{S}$), $\circ$) is a group. We will call any subgroup of Trans($\mathscr{S}$) a **transformation group**. An example is the set of collineations on $\mathbb{P}^2$. They form a subgroup **PR** of Trans($\mathbb{P}^2$) (Exercise 10). Harmonic sets are preserved by every element of **PR**, so we say that harmonic sets are an **invariant** of **PR**. On the other hand, distance and angle measure are not invariants for **PR**.

Klein used **PR** to categorize projective geometry, and he planned to use other groups, including subgroups of **PR**, to characterize other geometries by identifying their invariants under a given group. In this section we examine one such example. The texts of Bennett (1995, 18–33) and Eves (1965, 149–162), serve as general sources.

Affine Planes

Remember that Desargues defined the projective plane from the Euclidean plane by adding a line and points at infinity (Section 9.2). Let us now reverse that process and recoup the plane from $\mathbb{P}^2$. Let $\triangle E_1E_2E_3$ be the reference triangle (Figure 15.2). Let the ideal line ω be the line with equation $x_3 = 0$ and let all points on $x_3 = 0$ be the ideal points. These will be removed from the space but still used to identify parallel lines. Define lines l and m to be **parallel** if and only if l and m are different lines and there exists a point Ω on ω such that l and m both contain Ω. In Figure 15.2, both $\overline{AE_1}$ and $\overline{BE_1}$ are interpreted as being parallel to $\overline{E_1E_3}$.

When we remove the points with $x_3 = 0$, the remaining ordered triples in homogenous coordinates are of the form (kx_1, kx_2, kx_3), with both k and x_3 nonzero. However, since $x_3 \neq 0$, any of these points can be written as

$$(x_1/x_3, x_2/x_3, 1).$$

This means that we can uniquely identify each of these points by an ordered pair (x, y), where $x = x_1/x_3$ and $y = x_2/x_3$. These are called **nonhomogeneous coordinates**. Similarly, if we take a line that is represented using homogeneous coordinates $[a, b, c]$, its equation in homogeneous coordinates is

$$ax_1 + bx_2 + cx_3 = 0,$$

and letting $x = x_1/x_3$ and $y = x_2/x_3$, its equation in nonhomogeneous coordinates is

$$ax + by + c = 0. \tag{15.1}$$

Notice that if this line is parallel to

$$dx + ey + f = 0,$$

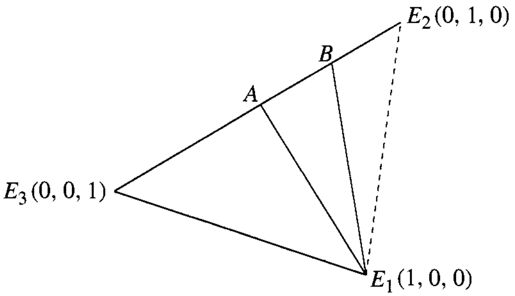

Figure 15.2 Interpreting $\overline{AE_1}$ and $\overline{AE_2}$ as parallel to $\overline{E_1E_2}$.

then

$$\begin{vmatrix} a & b \\ d & e \end{vmatrix} = 0.$$

If we convert these back to homogeneous coordinates, we obtain the system

$$\begin{array}{ccccccc} ax_1 & + & bx_2 & + & cx_3 & = & 0 \\ dx_1 & + & ex_2 & + & fx_3 & = & 0, \end{array}$$

which when put into a matrix and transform into row-reduced echelon form will look like either

$$\begin{bmatrix} 1 & * & * \\ 0 & 0 & 0 \end{bmatrix} \text{ or } \begin{bmatrix} 1 & * & 0 \\ 0 & 0 & 1 \end{bmatrix}.$$

The first form tells us that the lines are the same, while the second means that the point in common lies on the line $x_3 = 0$. This confirms that in our new geometry parallel lines meet at the line at infinity.

We now define new planes using nonhomogeneous coordinates. Let $(\mathcal{P}, \mathcal{L})$ be a projective plane with its points and lines identified by homogeneous coordinates. Define

$$\mathbb{A}(\mathcal{P}) = \{(x, y) : (x, y, 1) \text{ represents a point in } \mathcal{P}\}$$

and

$$\mathbb{L}(\mathcal{L}) = \{\{(x, y) : ax + by + c = 0\} : [a, b, c] \text{ represents an ordinary line in } \mathcal{L}\}.$$

Notice that $[0, 0, 1]$ is not used to define $\mathbb{L}(\mathcal{L})$. When we examine the basic properties of these two sets, we find that they satisfy the following list of postulates.

■ POSTULATES 15.2.1

Let $\mathcal{P}_A$ be a set of objects that are called **points** and $\mathcal{L}_A$ be a set of objects that are called **lines**.

1. For all distinct $P, Q \in \mathcal{P}_A$, there exists a unique line l in $\mathcal{L}_A$ such that P and Q are incident with l.
2. Every line contains at least two points.
3. There exists at least three noncollinear points.
4. Given a line l and a point P not on l, there exists exactly one line through P that is parallel to l.

We call the pair $(\mathcal{P}_A, \mathcal{L}_A)$ an **affine plane** if it satisfies the four postulates. It is left to Exercise 1 to show that $(\mathbb{A}(\mathcal{P}), \mathbb{L}(\mathcal{L}))$ is an affine plane for all projective planes $(\mathcal{P}, \mathcal{L})$. Other examples of affine planes include $\mathbb{R}^2$ and $\mathbb{Q}^2$, where the points are ordered pairs and the lines are sets of points that satisfy equations of the form given in Equation 15.1. In fact, $\mathbb{R}^2$ is the affine plane obtained from $\mathbb{P}^2$. A finite example is

$$\mathcal{P}_A = \{A, B, C, D\}$$

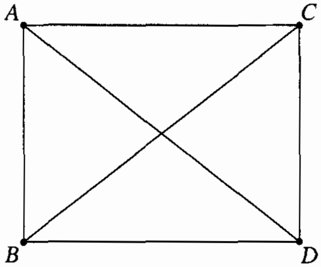
and

$$\mathcal{L}_A = \{\{A, B\}, \{A, C\}, \{A, D\}, \{B, C\}, \{B, D\}, \{C, D\}\}.$$

This affine plane is obtained from the Fano projective plane (Exercise 4). That this is the smallest affine plane is the result of the next theorem.

■ THEOREM 15.2.2

An affine plane has at least four points and at least six lines.



PROOF

By Postulate 3 of 15.2.1, there exists at least three noncollinear points in an affine plane. Let them be labeled A, B, and C. Join $\overline{AB}$, $\overline{AC}$, and $\overline{BC}$. These three lines are distinct. Since C is not on $\overline{AB}$, Postulate 4 guarantees a line on C that is parallel to $\overline{AB}$, and by Postulate 2 this line must contain a new point D. By the first postulate, join $\overline{BD}$ and $\overline{AD}$. The resulting diagram satisfies the postulates for an affine plane. ■

Notice that affine geometry feels a bit like projective geometry except that there are parallel lines. This is due not only to the construction of the affine plane from the projective plane but also because like projective geometry, affine geometry lacks a metric.

Affinities

A collineation on $\mathbb{R}^2$ is equivalent to a collineation on $\mathbb{P}^2$ that leaves the line $x_3 = 0$ fixed. No points can be mapped to or from it because it is not part of $\mathbb{R}^2$. By Theorem 14.4.6, the equations in homogeneous coordinates that describe these collineations are

$$\begin{bmatrix} kx_1' \\ kx_2' \\ kx_3' \end{bmatrix} = \begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix}, \tag{15.2}$$

where

$$\begin{vmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{vmatrix} \neq 0.$$

If we use nonhomogeneous coordinates, Equation 15.2 becomes

$$\begin{bmatrix} x' \\ y' \end{bmatrix} = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} + \begin{bmatrix} a_{13} \\ a_{23} \end{bmatrix}. \tag{15.3}$$

■ DEFINITION 15.2.3

The function $\phi : \mathbb{R}^2 \to \mathbb{R}^2$ is called an **affinity** if there exist an invertible 2×2 matrix A with real entries and vector $\mathbf{a}$ in $\mathbb{R}^2$ such that

$$\phi(\mathbf{x}) = A\mathbf{x} + \mathbf{a}.$$

Let **AF** denote the set of all affinities. We show that **AF** is a subgroup of **PR**. To do this, first note that by our work on the bottom of page 532, $\mathbf{AF} \subseteq \mathbf{PR}$. Next take $\phi, \psi \in \mathbf{AF}$. This means that we can write ϕ as in Definition 15.2.3 and ψ as

$$\psi(\mathbf{x}) = B\mathbf{x} + \mathbf{b},$$

where $\det(B) \neq 0$ and $\mathbf{b} \in \mathbb{R}^2$. We check the three conditions of Theorem 15.1.9.

- **AF** is closed under composition because
$$(\phi \circ \psi)(\mathbf{x}) = \phi(B\mathbf{x} + \mathbf{b}) = AB\mathbf{x} + A\mathbf{b} + \mathbf{a},$$
which is an element of **AF** because AB is invertible and $A\mathbf{b} + \mathbf{a} \in \mathbb{R}^2$.
- Certainly, the identity map is an element of **AF**.
- Define $\psi(x) = A^{-1}\mathbf{x} - A^{-1}\mathbf{a}$ and calculate:
$$(\phi \circ \psi)(\mathbf{x}) = \phi(A^{-1}\mathbf{x} - A^{-1}\mathbf{a}) = A(A^{-1}\mathbf{x} - A^{-1}\mathbf{a}) + \mathbf{a} = \mathbf{x}$$
and
$$(\psi \circ \phi)(\mathbf{x}) = \psi(A\mathbf{x} + \mathbf{a}) = A^{-1}(A\mathbf{x} + \mathbf{a}) - A^{-1}\mathbf{a} = \mathbf{x}.$$
Therefore, $\psi = \phi^{-1}$.

Affinities preserve neither distance nor angle measure. For example, take the affinity ϕ defined by

$$\begin{bmatrix} x' \\ y' \end{bmatrix} = \begin{bmatrix} 1 & 2 \\ 4 & 5 \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} + \begin{bmatrix} 3 \\ 6 \end{bmatrix}. \tag{15.4}$$

Then, $\phi(0, 0) = (3, 6)$ and $\phi(1, 1) = (6, 15)$. We see that the distance between $(0, 0)$ and $(1, 1)$ is different from the distance between $(3, 6)$ and $(11, 29)$. Moreover, if we compare the angle of inclination α of the original segment with the angle of inclination β of the image, we compute that $\cos\alpha = 1/\sqrt{2}$ and $\cos\beta = 3/\sqrt{89}$, which imply that $\alpha \neq \beta$.

However, affinities do preserve parallel lines.

■ THEOREM 15.2.4

The image of two parallel lines under an affinity is two parallel lines.

PROOF

Let ϕ be an affinity of an affine plane, so we can view ϕ as a projective collineation that leaves the line at infinity fixed. Assume that lines l and m are parallel. We conclude that there exists an ideal point Ω that is incident with both l and m. Therefore, $\phi(\Omega)$ is an ideal point, and since ϕ is a collinearity, $\phi[l]$ and $\phi[m]$ must intersect at $\phi(\Omega)$. Hence, $\phi[l]$ and $\phi[m]$ are parallel. ■

Exercises

1. Prove that $(\mathbb{A}(\mathcal{P}), \mathbb{L}(\mathcal{L}))$ is an affine plane for all projective planes $(\mathcal{P}, \mathcal{L})$.

2. Can $\mathbb{Z}^2$ be considered an affine plane?

3. Let $\mathcal{P}_A = \{A, B, C, D\}$ and

$$\mathcal{L}_A = \{\{A, B\}, \{A, C\}, \{A, D\}, \{B, C\}, \{B, D\}, \{C, D\}\}.$$

   (a) Show that $(\mathcal{P}_A, \mathcal{L}_A)$ is an affine plane.
   (b) Find all affinities of $(\mathcal{P}_A, \mathcal{L}_A)$.

4. Can the Fano plane (Theorem 14.1.4) be considered an affine plane? Explain.

5. In Figure 14.2 of the Fano plane, let $A = (0, 1, 0)$, $E = (0, 0, 1)$, $G = (1, 0, 0)$, and $C = (1, 1, 1)$.
   (a) Find the homogeneous coordinates for B, D, and F.
   (b) Which line in Figure 14.2 should be considered the line at infinity?
   (c) If possible, find the nonhomogeneous coordinates for A, B, C, D, E, F, and G.
   (d) Let $\mathbb{A}$ represent the ordered pairs in nonhomogeneous coordinates from Exercise 5(c). Let $\mathbb{L}$ be the set of lines through the points of $\mathbb{A}$. Find $\mathbb{L}$.
   (e) Show that $(\mathbb{A}, \mathbb{L})$ is an affine plane.
   (f) Find an affinity $\phi : \mathbb{A} \to \mathbb{A}$ such that $\phi(E) = E$, $\phi(B) = F$, and $\phi(F) = B$. Write the function in matrix form (Equation 15.3).
   (g) Two affine planes are **isomorphic** if there exists a collineation between them (compare Definition 14.1.6). Using the affine plane $(\mathcal{P}_A, \mathcal{L}_A)$ from Exercise 3, show that $(\mathbb{A}, \mathbb{L})$ is isomorphic to $(\mathcal{P}_A, \mathcal{L}_A)$.

6. Let $(\mathcal{P}_A, \mathcal{L}_A)$ be an arbitrary affine plane. Prove the following.
   (a) Two distinct lines in $\mathcal{L}_A$ have at most one point in common.
   (b) For all $l, m, n \in \mathcal{L}_A$, if m and n intersect and l is parallel to m, then l intersects n.
   (c) If there exists a line in $\mathcal{L}_A$ that contains n points, all lines in $\mathcal{L}_A$ contains n points.
   (d) For all $l, m \in \mathcal{L}_A$, let $l \sim m$ if and only if $l = m$ or l is parallel to m. Show that $\sim$ is an equivalence relation.

7. Can an affine plane be constructed with 10 points? 16 points? Explain.

8. Which of Postulates 14.1.2 are implied by Postulates 15.2.1?

9. Prove that Postulates 15.2.1 are consistent and independent.

10. Confirm that the set of collineations form a subgroup of Trans$(\mathbb{P}^2)$.

11. Find the homogeneous coordinates for the point $(4, 10)$ given in nonhomogeneous coordinates, and give the nonhomogeneous coordinates for the homogeneous $(4, 10, 7)$.

12. Write the function given in Equation 15.4 using homogeneous coordinates.

13. Let $\phi : \mathbb{R}^2 \to \mathbb{R}^2$ be an affinity such that $\phi(1, 1) = (4, 0)$ and $\phi(3, 2) = (2, 6)$. Give an equation for ϕ in the form $\phi(\mathbf{x}) = A\mathbf{x} + \mathbf{a}$.

14. A **dilatation** is a collineation $\phi : \mathbb{R}^2 \to \mathbb{R}^2$ such that for all lines l, $\phi[l]$ is parallel to l.

   (a) Why is a dilatation an affinity?
   (b) Draw an example of a dilatation in $\mathbb{R}^2$ and give its equation in the form $\phi(\mathbf{x}) = A\mathbf{x} + \mathbf{a}$.
   (c) Is the set of dilatations a group under composition?
   (d) Prove that a dilatation that has two invariant points is the identity map.
   (e) A **stretch** is an affinity ψ so that $\psi(x, y) = (kx, ky)$ for some k. Show that a stretch is a dilatation.

15. An **affine translation** is the identity map or a dilatation with no fixed points. Show that the set of affine translations is a group under composition.

16. Let τ be an affine translation and ϕ an affinity. Prove that $\phi^{-1} \circ \tau \circ \phi$ is an affine translation.

17. An affinity ϕ such that $\phi(A) = B$ is a **shear** if it fixes every point on lines that are parallel but not equal to $\overline{AB}$.

   (a) Draw an example of a shear in $\mathbb{R}^2$ and give its equation in the form $\phi(\mathbf{x}) = A\mathbf{x} + \mathbf{a}$.
   (b) Does the set of shears form a group under composition? Explain.

18. An affinity ψ is an **affine reflection** if for some points A and B, $\psi(A) = B$, $\psi(B) = A$, and there exists a point C not on $\overline{AB}$ such that $\psi(C) = C$.

   (a) Draw an example of an affine reflection in $\mathbb{R}^2$ and give its equation in the form $\psi(\mathbf{x}) = A\mathbf{x} + \mathbf{a}$.
   (b) Does the set of affine reflections form a group under composition?
   (c) Let M be the midpoint of $\overline{AB}$. Show that ψ fixes every point on $\overline{CM}$.

15.3 THE PRINCIPAL GROUP

Jordan taught his students that transformation groups would one day play an important role in the development of geometry. This was realized by the work of Klein and Lie. Influenced by what they learned in Paris, Klein focused on discrete groups, while Lie made studying **continuous groups** a lifelong project. Examples of these uncountable groups include $(\mathbb{R}, +)$ and the groups of projective and affine transformations. Initially, however, Klein's and Lie's group theoretic interests coincided with the group of transformations of the Euclidean plane (Yaglom 1988, 95, 97).

As projective geometry can be defined as the study of the properties that remain invariant under the group of projectivities, Klein defined Euclidean geometry as the study of properties that are preserved under transformations of the Euclidean plane.

To understand the reason for his definition, we need to go back to Euclid. Although he used it reluctantly, Euclid applied superposition to prove SAS (page 138). He assumed that he could take a triangle and move it so that it aligned with any other triangle to which it was congruent. As the triangle moved, it did not deform. Its sides remained the same length and its angles kept their measure. Euclid also studied similar figures. Two figures are similar if there exists a transformation that changes only the size of the figure, not its angle measures. All of this means that Euclid indirectly applied transformations of the plane that preserved both distance and angle measure. With this in mind, Klein (1893, 218) made the following definition.

■ **DEFINITION 15.3.1**

The **principal group PG** is the transformation group on $\mathbb{R}^2$ that consists of the following functions:

- motions in the plane (translations, rotations)
- transformations into symmetrical figures (reflections)
- transformations into similar figures (dilations and contractions)
- any composition of the above

Isometries

All of the maps of the principal group are conformal, but the first two are also guaranteed to preserve distance. Throughout, let d represent the standard metric.

■ **DEFINITION 15.3.2**

A one-to-one correspondence $f : \mathbb{R}^2 \to \mathbb{R}^2$ is an **isometry** if

$$d[A, B] = d[f(A), f(B)]$$

for all $A, B \in \mathbb{R}^2$. In this case we say that f **preserves distance**.

We begin by proving three basic properties of isometries.

■ **THEOREM 15.3.3**

An isometry is a collineation.

PROOF

Let ϕ be an isometry and assume that $\phi(A) = A'$ and $\phi(B) = B'$. Take P on $\overline{AB}$. To obtain a contradiction, suppose that $\phi(P) = P'$ is not on $\overline{A'B'}$. By the Triangle Inequality (5.3.11),

$$A'B' < A'P' + P'B'.$$

However, this is impossible because

$$A'B' = AB = AP + PB = A'P' + P'B'.$$

Therefore, P' is on $\overline{A'B'}$. ■

■ THEOREM 15.3.4

Isometries are conformal.

PROOF

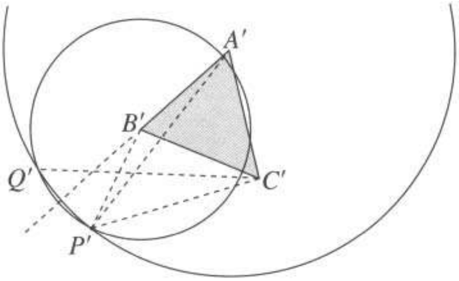
Let $f : \mathbb{R}^2 \to \mathbb{R}^2$ be an isometry and choose three points A, B, C in $\mathbb{R}^2$. Then

$$\begin{aligned} d[A, B] &= d[\phi(A), \phi(B)], \\ d[A, C] &= d[\phi(A), \phi(C)], \\ d[B, C] &= d[\phi(B), \phi(C)]. \end{aligned}$$

Thus, by SSS, $\triangle ABC \cong \triangle f(A)f(B)f(C)$, from which we conclude that $\sphericalangle ABC \cong \sphericalangle f(A)f(B)f(C)$. ■

■ THEOREM 15.3.5

An isometry is uniquely determined by three noncollinear points.



PROOF

Let A, B, and C be distinct noncollinear points. Let ϕ and ψ be two isometries and assume that

$$\phi(A) = \psi(A) = A', \ \phi(B) = \psi(B) = B', \text{ and } \phi(C) = \psi(C) = C'.$$

We need to show that $\phi = \psi$. To do this, take any point P in the plane and let $\phi(P) = P'$. We will show that P' is uniquely determined by its distance to each of the points A', B', and C', thus showing that $\phi(P) = \psi(P)$. Suppose that there is another point Q' that has the same distances from A', B', and C' as P'. We can then draw $\odot A'$ with radius $\overline{A'P'}$ and $\odot B'$ with radius $\overline{B'P'}$ such that Q' is also on the intersection of the two circles. Join $\overline{C'Q'}$ and $\overline{C'P'}$. The only way that these two segments can be congruent is for C' to lie on the perpendicular bisector of $\overline{Q'P'}$. However, this is not the case because the $\overline{A'B'}$ produced is that perpendicular bisector and C' is not collinear with A' and B'. Therefore, Q' does not exist, and P' is described uniquely by its distances to A', B', and C'. Since the distances from $\phi(A)$, $\phi(B)$, and $\phi(C)$ to P', respectively, equal the distances from $\psi(A)$, $\psi(B)$, and $\psi(C)$ to P', it must be the case that $\psi(P) = P'$ since ψ preserves distances. ■

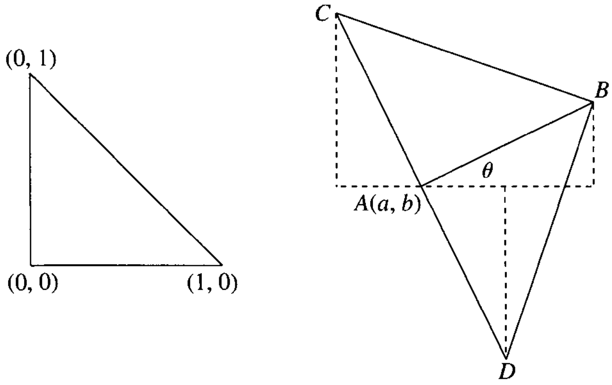
The fact that three noncollinear points determine an isometry uniquely will enable us to show that all isometries are affinities.

■ THEOREM 15.3.6

A function $\phi : \mathbb{R}^2 \to \mathbb{R}^2$ is an isometry if and only if there exists a 2×2 matrix A, a vector $\mathbf{b} \in \mathbb{R}^2$, and an angle θ such that either

$$A = \begin{bmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{bmatrix} \text{ or } A = \begin{bmatrix} \cos\theta & \sin\theta \\ \sin\theta & -\cos\theta \end{bmatrix}$$

and $\phi(\mathbf{x}) = A\mathbf{x} + \mathbf{b}$.



PROOF

We leave to Exercise 4 the proof that $\phi(\mathbf{x}) = A\mathbf{x} + \mathbf{b}$ with A and $\mathbf{b}$ as described is an isometry. So to prove the converse, let ϕ be an isometry. First suppose that $\phi(0, 0) = (a, b) = A$. We have two cases to check, depending on whether ϕ preserves the orientation of the vertices of the triangle. Assume that it does. This means that $\phi(1, 0) = B$ and $\phi(0, 1) = C$, as in the diagram. Let θ be the angle of inclination of $\overline{AB}$. Then, since $AB = 1$,

$$\phi(1, 0) = (a + \cos\theta,\ b + \sin\theta),$$
$$\phi(0, 1) = (a - \sin\theta,\ b + \cos\theta).$$

Since ϕ is an isometry, we may conclude by Theorem 15.3.5 that

$$\phi(x, y) = \begin{bmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} + \begin{bmatrix} a \\ b \end{bmatrix}$$

because a function of this form is an isometry (Exercise 4). If the isometry does not preserve the order of the vertices, then $\phi(0, 1) = D$ and

$$\phi(0, 1) = (a + \cos(\theta - \pi/2), b + \sin(\theta - \pi/2)) = (a + \sin\theta, b - \cos\theta).$$

Therefore,

$$\phi(x, y) = \begin{bmatrix} \cos\theta & \sin\theta \\ \sin\theta & -\cos\theta \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} + \begin{bmatrix} a \\ b \end{bmatrix},$$

again due to Theorem 15.3.5. ■

Since both versions of A in the theorem have a nonzero determinant, we may conclude the following result.

■ COROLLARY 15.3.7

An isometry of $\mathbb{R}^2$ is an affinity.

Now to confirm the group structure of the set of isometries. We leave the proof of the first part of the lemma to Exercise 7.

■ LEMMA 15.3.8

- The composition of isometries is an isometry.
- The inverse of an isometry is an isometry.

PROOF

Let $f : \mathbb{R}^2 \to \mathbb{R}^2$ be an isometry. Take $X', Y' \in \mathbb{R}^2$ and let X and Y be in the plane so that $f^{-1}(X') = X$ and $f^{-1}(Y') = Y$, which means that $f(X) = X'$ and $f(Y) = Y'$. Therefore,

$$d[X', Y'] = d[f(X), f(Y)] = d[X, Y] = d[f^{-1}(X'), f^{-1}(Y')]. \blacksquare$$

Lemma 15.3.8 combined with the fact that the identity is an isometry yield the next theorem.

■ THEOREM 15.3.9

The set of isometries of $\mathbb{R}^2$ is a subgroup of the principal group.

Similarities

Isometries are conformal and preserve distances. If we require a transformation on $\mathbb{R}^2$ to only be conformal, we obtain another group of functions of the plane.

■ DEFINITION 15.3.10

The transformation $\sigma : \mathbb{R}^2 \to \mathbb{R}^2$ is a **similarity** if there exists $r > 0$ such that for all $A, B \in \mathbb{R}^2$, if $A' = \sigma(A)$ and $B' = \sigma(B)$, then $A'B' = rAB$. The real number r is called the **ratio** of the similarity.

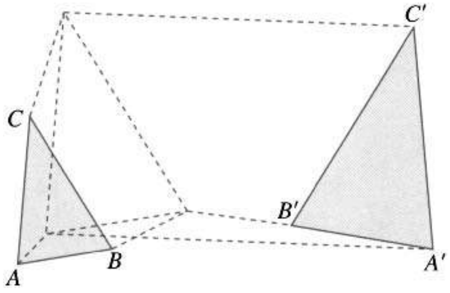


Figure 15.3 $\triangle A'B'C'$ is the image of $\triangle ABC$ under a similarity.

The similarity σ_0 defined by $\sigma_0(x, y) = (rx, ry)$ is an example of a **homothety** (Exercise 12). It leaves the origin fixed and either dilates or contracts all other points, depending on the value of r. To obtain formulas for the other similarities, take an isometry ϕ and compose it with σ_0 (Figure 15.3). That the resulting composition is a similarity is seen by

$$\|(\phi \circ \sigma_0)(x, y)\| = \|\phi(rx, ry)\| = \|(rx, ry)\| = r\|(x, y)\|,$$

where the second equality holds because ϕ is an isometry. This result can be used to prove the following characterization of similarities (Exercise 11).

■ THEOREM 15.3.11

If σ is a similarity with ratio r, there exists a 2×2 invertible matrix A and a vector $\mathbf{b} \in \mathbb{R}^2$ such that

$$\sigma(\mathbf{x}) = rA\mathbf{x} + \mathbf{b},$$

where

$$\phi(\mathbf{x}) = A\mathbf{x} + \mathbf{b}$$

is an isometry.

■ COROLLARY 15.3.12

A similarity is an affinity.

Similarities do share some properties with isometries. The following is an example. Its proof is a modification of Theorems 15.3.3 and 15.3.4 (Exercise 16).

■ THEOREM 15.3.13

A similarity is a conformal collineation.

The similarities also form a subgroup of the principal group. To see this, we first show that the set of similarities is closed under composition.

■ LEMMA 15.3.14

The composition of similarities is a similarity.

PROOF

Let σ_1 and σ_2 be similarities with ratios r_1 and r_2. Then there are invertible matrices A_1 and A_2 with $\mathbf{b}_1$, $\mathbf{b}_2 \in \mathbb{R}^2$ so that $A_1\mathbf{x}+\mathbf{b}_1$ and $A_2\mathbf{x}+\mathbf{b}_2$ represent isometries and

$$\sigma_1(\mathbf{x}) = r_1A_1\mathbf{x} + \mathbf{b}_1 \text{ and } \sigma_2(\mathbf{x}) = r_2A_2\mathbf{x} + \mathbf{b}_2.$$

We now compute for all $\mathbf{x} \in \mathbb{R}^2$,

$$\begin{aligned}\|(\sigma_1 \circ \sigma_2)(\mathbf{x})\| &= \|\sigma_1(r_2A_2\mathbf{x} + \mathbf{b}_2)\| \\ &= \|r_1r_2A_1A_2\mathbf{x} + r_1A_1\mathbf{b}_2 + \mathbf{b}_1\| \\ &= r_1r_2\left\|A_1A_2\mathbf{x} + \frac{1}{r_2}A_1\mathbf{b}_2 + \frac{1}{r_1r_2}\mathbf{b}_1\right\| \\ &= r_1r_2\|\mathbf{x}\|.\end{aligned}$$

The last equality follows from the fact proven in Lemma 15.3.8 that the composition of isometries is an isometry (Exercise 8). Therefore, we conclude that $\sigma_1 \circ \sigma_2$ is a similarity. ■

The lemma, together with the facts that the identity map is a similarity with $r = 1$ and the inverse of a similarity with ratio r is a similarity with ratio $1/r$ (Exercise 13), gives us the next theorem.

■ THEOREM 15.3.15

- The set of similarities form a subgroup of the principal group.
- The set of isometries form a subgroup of the set of similarities.

Many more results concerning isometries and similarities, including applications, may be found in Dodge (1972, 48–130). That text served as the general reference for this section and the next.

Exercises

1. Define $f : \mathbb{R} \to \mathbb{R}$ by $f(x) = x^3 + 1$.
   (a) Prove that f is a transformation.
   (b) Define what it would mean for f to be an isometry on $\mathbb{R}$. Based on the definition chosen, show that f not an isometry.
   (c) Find an example of an isometry on $\mathbb{R}$. Must it be linear?
2. Let $g : \mathbb{R}^2 \to \mathbb{R}^2$ be defined by $g(x, y) = (x + 2, y^5 - 1)$.
   (a) Prove that g is a transformation.
   (b) Is g an isometry? Explain.

3. Prove directly from the definition that $f(x, y) = (x - 7, y + 5)$ is an isometry.

4. Prove that $\phi(\mathbf{x}) = A\mathbf{x} + \mathbf{b}$ is an isometry if either

$$A = \begin{bmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{bmatrix} \text{ or } A = \begin{bmatrix} \cos\theta & \sin\theta \\ \sin\theta & -\cos\theta \end{bmatrix}.$$

5. Prove that isometries preserve the areas of rectangles and triangles. Do isometries preserve the areas of all plane figures?

6. Prove that the image of a circle under an isometry is a circle.

7. Prove that the composition of isometries is an isometry (Lemma 15.3.8).

8. Let ϕ be an isometry. Show that for all $\mathbf{b} \in \mathbb{R}^2$, $\psi(\mathbf{x}) = \phi(\mathbf{x}) + \mathbf{b}$ is an isometry.

9. Is an isometry that fixes three noncollinear points the identity map? Explain.

10. Let $g(x, y) = (4x + 2, 4y - 8)$. Prove that g is a similarity.

11. Prove Theorem 15.3.11.

12. Given a point C called the **center** and $r > 0$, a **homothety** η is a transformation of the plane such that for all points A,

$$d[\eta(A), C] = rd[A, C].$$

- (a) Prove that a homothety has only one fixed point.
- (b) Show that the composition of two homotheties with the same center is a homothety. Identify the composition's ratio and center.
- (c) Let $\triangle ABC$ and $\triangle A'B'C'$ be similar but not congruent triangles such that corresponding sides are parallel. Find a homothety η such that the image of $\triangle ABC$ under η is $\triangle A'B'C'$.
- (d) Prove or disprove: The set of homotheties form a subgroup of the set of similarities.

13. Prove that the inverse of a similarity with ratio r is a similarity with ratio $1/r$.

14. Is the group of similarities abelian? Explain.

15. Let σ be a similarity with ratio r. If $r \geqslant 1$, then σ is a **dilation**, and if $0 < r < 1$, then σ is a **contraction**. Is the set of dilations a subgroup of the group of similarities? What about the set of contractions? Explain.

16. Prove Theorem 15.3.13

17. Let σ be an similarity with ratio r. Let $\mathcal{F}$ be a convex figure in the plane. True or false: The area of $\sigma[\mathcal{F}]$ equals r^2 times the area of $\mathcal{F}$. Give an example.

18. Prove the following for transformations of $\mathbb{R}^2$:
- (a) The composition of conformal maps is conformal.
- (b) The inverse of a conformal map is conformal.

19. Define $\phi(\mathbf{x}) = rA\mathbf{x} + \mathbf{b}$. For each A and $\mathbf{b}$ given, find ϕ^{-1}, the image of the triangle with vertices (0, 0), (1, 0), and (0, 1), and whether ϕ is an isometry or a similarity.

(a) $A = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}, \mathbf{b} = \begin{bmatrix} -4 \\ 3 \end{bmatrix}$.

(b) $A = \begin{bmatrix} \sqrt{2}/2 & -\sqrt{2}/2 \\ \sqrt{2}/2 & \sqrt{2}/2 \end{bmatrix}, \mathbf{b} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$.

(c) $A = \begin{bmatrix} 2\sqrt{3} & -2 \\ 2 & 2\sqrt{3} \end{bmatrix}, \mathbf{b} = \begin{bmatrix} 1 \\ 2 \end{bmatrix}$.

15.4 ISOMETRIES OF THE PLANE

There are four different types of isometries of the principal group. In this section we examine each and then prove that there are no other types.

Reflections

We begin our introduction to the transformations of the principal group by defining the function that is used to determine the symmetries of a plane figure. These functions also have the property that they map figures to congruent figures.

■ DEFINITION 15.4.1

The transformation $\mu : \mathbb{R}^2 \to \mathbb{R}^2$ is a **reflection** through a line l if for all $A \in \mathbb{R}^2$, if A is not on l, the line l is the perpendicular bisector of the segment joining A and $\mu(A)$, otherwise $\mu(A) = A$. We call l the **mirror** of the reflection.

The definition is illustrated in Figure 15.4. Although a reflection is an isometry and every reflection is its own inverse (Exercise 6), the diagram makes clear that the

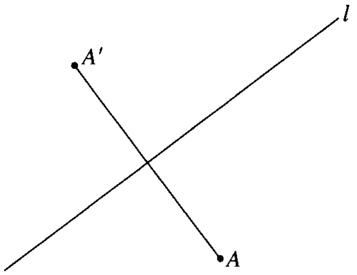

Figure 15.4 A reflection of A to image A' through l.

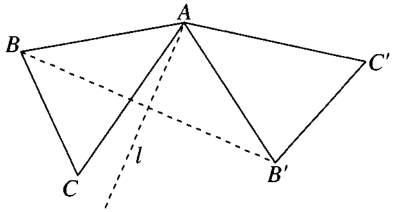
identity is not a reflection. Hence, the set of reflections do not form a subgroup of the principal group. Instead, they serve as the building blocks for the group of isometries.

■ THEOREM 15.4.2

Every isometry is the composition of at most three reflections.



PROOF

Let ϕ be an isometry on $\mathbb{R}^2$. By Theorem 15.3.5 it suffices to examine ϕ on any three noncollinear points A, B, and C. We have four cases to consider.

- Let $\phi(A) = A$, $\phi(B) = B$, and $\phi(C) = C$. This means that ϕ is the identity, so let μ be any reflection. Then $\phi = \mu \circ \mu$.

- Let $\phi(A) = A$, $\phi(B) = B$, and $\phi(C) \neq C$. In this case ϕ is a reflection with mirror $\overline{AB}$ (Exercise 4).

- Let $\phi(A) = A$, $\phi(B) = B' \neq B$, and $\phi(C) = C' \neq C$. This is illustrated in the diagram for this theorem. Since $\triangle ABB'$ is isosceles, A is on the perpendicular bisector l of $\overline{BB'}$. Therefore, the reflection μ with mirror l has

  $$\mu(A) = A \text{ and } \mu(B') = B,$$

  and then

  $$(\mu \circ \phi)(A) = A \text{ and } (\mu \circ \phi)(B) = \mu(B') = B.$$

  By the previous two cases, $\mu \circ \phi$ is either the identity or a reflection. If $\mu \circ \phi$ is the identity, ϕ is a reflection. If $\mu \circ \phi$ is a reflection, ϕ is the composition of two reflections.

- The case where $\phi(A) \neq A$, $\phi(B) \neq B$, and $\phi(C) \neq C$ is also left to Exercise 4. ■

The natural question to ask next is whether all reflections are isometries. The next proposition gives the answer. Since it can be proven either along the lines of Theorem 15.3.6 or by using methods from later in this section, its proof is left to Exercise 5.

■ THEOREM 15.4.3

The equation for the reflection μ with a mirror that has an angle of inclination $\theta/2$ and passes through the point (a, b) is

$$\mu(x, y) = \begin{bmatrix} \cos\theta & \sin\theta \\ \sin\theta & -\cos\theta \end{bmatrix} \begin{bmatrix} x-a \\ y-b \end{bmatrix} + \begin{bmatrix} a \\ b \end{bmatrix}.$$

The consequence of the theorem is that reflections are isometries because they can be written in the form of Theorem 15.3.6.

■ COROLLARY 15.4.4

Reflections are isometries.

Translations

The most basic plane motion is when a figure is slid in the direction of a given vector.

■ DEFINITION 15.4.5

The transformation $\tau : \mathbb{R}^2 \to \mathbb{R}^2$ is a **translation** if there exists a vector $\langle a, b\rangle$ such that

$$\tau(x, y) = (x + a, y + b).$$

We say that $\langle a, b\rangle$ **describes** τ. This is illustrated in Figure 15.5.

Observe that the translation τ in the definition can be written in the form

$$\tau(x, y) = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} + \begin{bmatrix} a \\ b \end{bmatrix}. \tag{15.5}$$

Conversely, any function of the form given in Equation 15.5 is a translation. Thus, we have a proposition that quickly follows from the definition by Theorem 15.3.6.

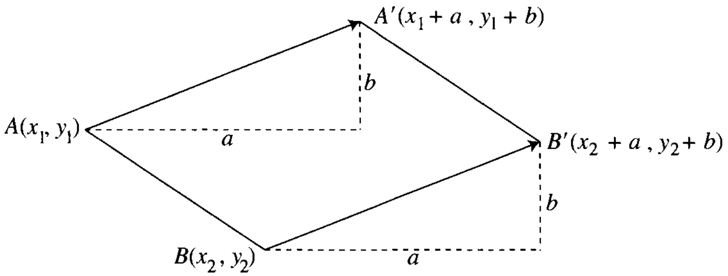


Figure 15.5 A translation of $\overline{AB}$ to image $\overline{A'B'}$.

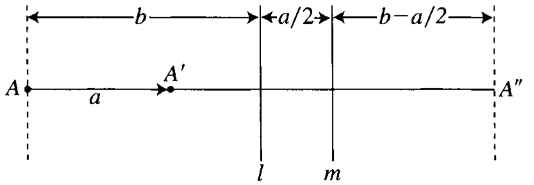
THEOREM 15.4.6

A translation is an isometry.

As an isometry, a translation can be written as the composition of at most three reflections (Theorem 15.4.2). The next theorem improves on that.

THEOREM 15.4.7

A transformation is a translation if and only if it is the composition of two reflections with parallel mirrors.



PROOF

We prove sufficiency. Take a vector of length a and let it describe a translation. Let l and m be two parallel lines that are perpendicular to the vector and are a distance $a/2$ apart. We claim that the translation is the composition of the reflection with mirror m and the reflection with mirror l. To prove this, let A be a point in the plane and let A' be its image under the translation. Let b be the distance from A to l. Take A'' to be the image of A by the reflection through l, so the distance from A to A'' is $2b$ and the distance from A'' to m is $b - a/2$, allowing for the possibility that this distance is signed. Now reflect A'' through m. Since $2b - 2(b - a/2) = a$, the image of this last reflection is A'. ■

We next want to show that the set of translations form a subgroup of the principal group under composition. For this we need some results.

LEMMA 15.4.8

The composition of translations is a translation.

PROOF

Let τ_1 and τ_2 be two translations of the plane. Let $\langle a_1, b_1\rangle$ be the vector that describes τ_1 and $\langle a_2, b_2\rangle$ be the vector that describes τ_2. When we compose the two functions, we find that

$$\begin{aligned}(\tau_1 \circ \tau_2)(x, y) &= \tau_1(\tau_2(x, y))\\ &= \tau_1(x + a_2, y + b_2)\\ &= ([x + a_2] + a_1, [x + b_2] + b_1)\\ &= (x + [a_2 + a_1], y + [b_2 + b_1]).\end{aligned}$$

The last ordered pair in this equation is that which defines the translation with vector $\langle a_2 + a_1, b_2 + b_1\rangle$. ■

Notice that although function composition is not generally commutative, it is in the case of translations. Namely, for any two translations τ_1 and τ_2,

$$\tau_1 \circ \tau_2 = \tau_2 \circ \tau_1.$$

This is because $\langle a_1 + a_2, b_1 + b_2 \rangle = \langle a_2 + a_1, b_2 + b_1 \rangle$.

■ LEMMA 15.4.9

If $\langle a, b \rangle$ describes the translation τ, $\langle -a, -b \rangle$ describes τ^{-1}.

PROOF

Let $\langle a, b \rangle$ describe τ and let $\langle -a, -b \rangle$ describe σ. We calculate:

$$(\tau \circ \sigma)(x, y) = \tau(x - a, y - b) = ([x - a] + a, [y - b] + b) = (x, y).$$

Therefore, $\tau \circ \sigma$ is the identity map. Since we know that composition is commutative for translations, we conclude that $\sigma \circ \tau$ is also the identity map. Thus, $\sigma = \tau^{-1}$. ■

The previous two lemmas, plus the fact that the identity map is a translation, allow us to draw our conclusion.

■ THEOREM 15.4.10

The set of translations of $\mathbb{R}^2$ is an abelian subgroup of the principal group.

Rotations

To rotate a point A around a center point O means to move A along the arc of a circle with center O and radius of length OA through a fixed angle measure θ. The result of the motion is A' in Figure 15.6. Algebraically, this means the following: Let (x, y) be a point in $\mathbb{R}^2$. Let ρ be the transformation that rotates (x, y) to (x', y') along an arc of measure θ radians around the origin. Let r be the radius, so

$$r = \sqrt{x^2 + y^2},$$

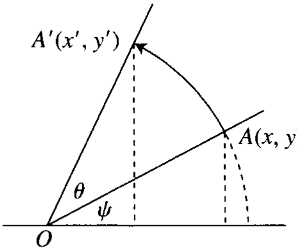


Figure 15.6 A rotation of A about the origin to image A'.

and let ψ be the angle that the line through the origin and (x, y) makes with the x-axis. This means that

$$x = r\cos\psi,\ y = r\sin\psi$$

and

$$x' = r\cos(\theta + \psi),\ y' = r\sin(\theta + \psi).$$

Using the addition formulas from trigonometry yields

$$x' = r\cos\theta\cos\psi - r\sin\theta\sin\psi = x\cos\theta - y\sin\theta$$

and

$$y' = r\sin\theta\cos\psi + r\cos\theta\sin\psi = x\sin\theta + y\cos\theta.$$

■ DEFINITION 15.4.11

The transformation $\rho : \mathbb{R}^2 \to \mathbb{R}^2$ is a **rotation** about the origin if there exists an angle measure θ such that

$$\rho(x, y) = (x\cos\theta - y\sin\theta,\ x\sin\theta + y\cos\theta).$$

We say that θ **describes** ρ.

We will not specifically define a function that represents a rotation about an arbitrary point. Instead, we compose translations with a rotation about the origin. Fix the point P with coordinates (a, b). Let τ be the translation described by $\langle -a, -b\rangle$ and ρ the rotation described by θ. The function

$$\tau^{-1} \circ \rho \circ \tau$$

is the rotation about P of measure θ (Figure 15.7). From this we can show that an arbitrary rotation with center (a, b) has the form

$$\rho(x, y) = \begin{bmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{bmatrix} \begin{bmatrix} x - a \\ y - b \end{bmatrix} + \begin{bmatrix} a \\ b \end{bmatrix}. \tag{15.6}$$

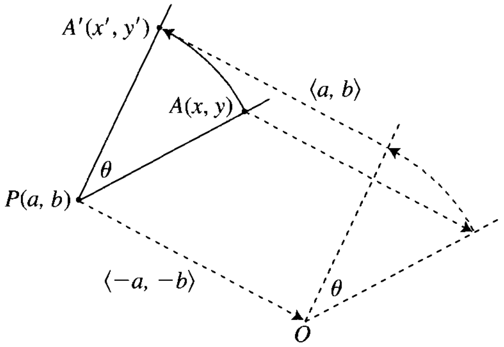

Figure 15.7 A rotation of A about P to image A'.

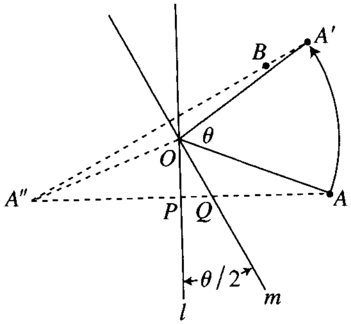
Moreover, any equation of the form given in Equation 15.6 is a rotation.

As with translations, we can write a rotation as a composition of two reflections.

■ THEOREM 15.4.12

A transformation is a rotation if and only if it is the composition of two reflections with intersecting mirrors.



PROOF

We prove sufficiency. Let O be the center of the rotation and θ its angle. Let A be a point in the plane and A' its image under the rotation. Choose any line l containing O and let m also be through O, forming an angle of measure $\theta/2$ measured counterclockwise from l. Let A'' be the image of A under the reflection through mirror l and B the image of A'' through the mirror m. Then

$$\triangle A''PO \cong \triangle APO$$

by SAS. From this we conclude that $\overline{OA''} \cong \overline{OA}$, so A, A', and A'' lie on the same circle with center O. Moreover, letting Q be the intersection of m and $\overline{A''A}$, we see that $m\sphericalangle QA''B = \theta/2$ because this angle is the complement of $\sphericalangle OQP$. Therefore, the point B is actually the point A' because $\sphericalangle QA''A$ has the measure of an inscribed angle in $\odot O$ that intercepts $\overset{\frown}{AA'}$. Hence, A reflected through l and then through m results in A'. ■

■ COROLLARY 15.4.13

A rotation is an isometry.

We now identify the group structure of rotations. The first lemma involves the composition of two rotations. Supposing that they are both centered at the same point, the composition is another rotation about that point. Otherwise, we might obtain a translation.

■ LEMMA 15.4.14

The composition of two rotations is either a rotation or a translation.

PROOF

Let ρ_1 and ρ_2 be rotations about the points O and P, respectively. Let θ_1 be the angle the describes ρ_1 and θ_2 be the angle that describes ρ_2. Join $\overline{OP}$. As in the proof of Theorem 15.4.12, find l through O and a line m through P such that the measure of the angle from l to $\overline{OP}$ is $\theta_1/2$ and the measure of the angle from $\overline{OP}$ to m is $\theta_2/2$. That is,

$$\rho_1 = \mu_2 \circ \mu_1$$

and

$$\rho_2 = \mu_3 \circ \mu_2,$$

where μ_1 is the reflection with mirror l, μ_2 is the reflection with mirror $\overline{OP}$, and μ_3 is the reflection with mirror m. Thus,

$$\rho_2 \circ \rho_1 = \mu_3 \circ \mu_2 \circ \mu_2 \circ \mu_1 = \mu_3 \circ \mu_1.$$

If l and m are parallel, the composition is a translation (Theorem 15.4.7), otherwise it is a rotation (Theorem 15.4.12). ■

The next proposition states that the inverse of a rotation is the rotation in the opposite direction. Its proof is Exercise 14.

■ LEMMA 15.4.15

If θ describes the rotation ρ, then $-\theta$ describes ρ^{-1}.

We now have the pieces to prove that these transformations have a group structure under composition (Exercise 8).

■ THEOREM 15.4.16

The following are subgroups of the principal group. The first subgroup is abelian, but the second is not.

- The set of rotations about a given point.
- The set of translations and rotations.

There is one more transformation needed to complete our list of isometries. A **glide reflection** γ (Figure 15.8) is the composition of a reflection with mirror l and a translation described by a vector $\mathbf{v}$ that is parallel to l with angle of inclination θ. By Theorem 15.4.3 and Equation 15.5, the equation for a glide reflection with a mirror through a point (a, b) can be described by a function of the form

$$\gamma(x, y) = \begin{bmatrix} \cos\theta & \sin\theta \\ \sin\theta & -\cos\theta \end{bmatrix} \begin{bmatrix} x - a \\ y - b \end{bmatrix} + \begin{bmatrix} a + \|\mathbf{v}\| \cos\theta \\ b + \|\mathbf{v}\| \sin\theta \end{bmatrix} \tag{15.7}$$

Hence, when we examine the general form of an isometry given by Theorem 15.3.6 with Theorem 15.4.3 and Equations 15.5, 15.6, and 15.7, we can conclude that the translations of this section exhaust all possibilities for isometries in the plane. Therefore, we write the following result.

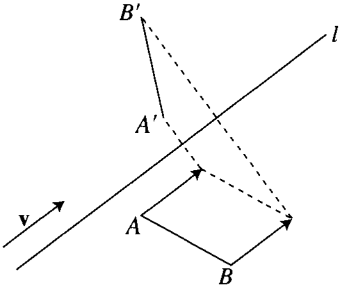


Figure 15.8 A glide reflection with vector **v** and mirror l.

■ THEOREM 15.4.17

The set of reflections, translations, rotations, and glide reflections of the plane is identical to the set of isometries.

Exercises

1. Find the image of the triangle with vertices $(0,\ 0)$, $(1,\ 0)$, and $(0,\ 1)$ under the following isometries.
   (a) a reflection with mirror $y = -4$
   (b) a reflection with mirror $2x + 5y = 1$
   (c) a translation described by vector $\langle 2,\ -3\rangle$
   (d) a translation $4\sqrt{2}$ units along the line $y = x$
   (e) a rotation about the origin of measure $\pi/6$
   (f) a rotation about the point $(-4,\ -3)$ of measure $3\pi/4$
   (g) a glide reflection with mirror $x = 3$ and vector $\langle 0,\ 4\rangle$
   (h) a glide reflection with mirror $x - 2y = 10$ and vector $\langle 2,\ 1\rangle$

2. For the transformations of Exercise 1.
   (a) Write each as a reflection or product of reflections.
   (b) Write each in the form $\phi(\mathbf{x}) = A\mathbf{x} + \mathbf{b}$, where A is a 2×2 invertible matrix and $\mathbf{b}$ a vector in the plane.
   (c) Find the inverse of each transformation geometrically and then find it algebraically using the form $\phi(\mathbf{x}) = A\mathbf{x} + \mathbf{b}$.

3. Identify all isometries that can map the given figure to itself.
   (a) equilateral triangle
   (b) square
   (c) regular hexagon
   (d) parallelogram

4. Prove the second and fourth cases in the proof of Theorem 15.4.2.

5. Prove Theorem 15.4.3.

6. Prove that a reflection is an isometry and a reflection is its own inverse.

7. Prove necessity for Theorems 15.4.7 and 15.4.12.

8. Prove Theorem 15.4.16.

9. How can a reflection be used to show that the base angles of an isosceles triangle are congruent?

10. Let A and B be distinct points in the plane. Prove that there exists exactly one reflection μ so that $\mu(A) = B$.

11. Show that the composition of three reflections is a reflection or a glide reflection.

12. Define $\mathscr{G}$ to be the set of translations described by a vector with integer coordinates. Show that $\mathscr{G}$ is a subgroup of the set of translations.

13. Show that the composition of two homotheties is a translation or a homothety.

14. Prove that if θ describes the rotation ρ, then $-\theta$ describes ρ^{-1}.

15. Prove that the composition of two rotations about the same point is another rotation about that point.

16. Let $n \in \mathbb{Z}$ and define $\mathscr{G}_n$ to be the set of rotations about the origin of measure $2k\pi/n$ $(k \in \mathbb{Z})$. Prove that $\mathscr{G}_n$ is a subgroup of the set of all rotations about the origin.

17. Does the set of glide reflections form a subgroup of the principal group?

18. What is the inverse of a glide reflection?

19. Give the equation for the image of the line $2x-y = 0$ under the given isometries.
    (a) a reflection with mirror $x + 5y = 3$
    (b) a translation described by the vector $\langle -3, 7\rangle$
    (c) a rotation of measure $\pi/6$ about the point $(1, 2)$
    (d) a glide reflection with mirror $x + y = 6$ and vector $\langle 3, -3\rangle$

20. Let $a, b \in \mathbb{R}$. Show for all $(x_1, y_1), (x_2, y_2) \in \mathbb{R}^2$,

$$d[(x_1, y_1), (x_2, y_2)] = d[(x_1 + a, y_1 + b), (x_2 + a, y_2 + b)]$$

and

$$d[(x_1, y_1), (x_1 + a, y_1 + b)] = d[(x_2, y_2), (x_2 + a, y_2 + b)].$$

21. We say that a plane figure $\mathscr{F}$ is **symmetric** with respect to a line l if given the reflection μ with mirror l, $\phi[\mathscr{F}] = \mathscr{F}$. In this case, l is called a **line of symmetry** for $\mathscr{F}$. Find the lines of symmetry of the given figures.
    (a) equilateral triangle
    (b) regular hexagon
    (c) parallelogram

22. Using the definition given in Exercise 21, show the each figure is symmetric through the given lines.
    (a) parallelogram through a diagonal
    (b) a triangle through a median
    (c) circle through a diameter
    (d) a regular pentagon through the line connecting a vertex with the midpoint of the opposite side

15.5 CONSISTENCY OF EUCLIDEAN GEOMETRY

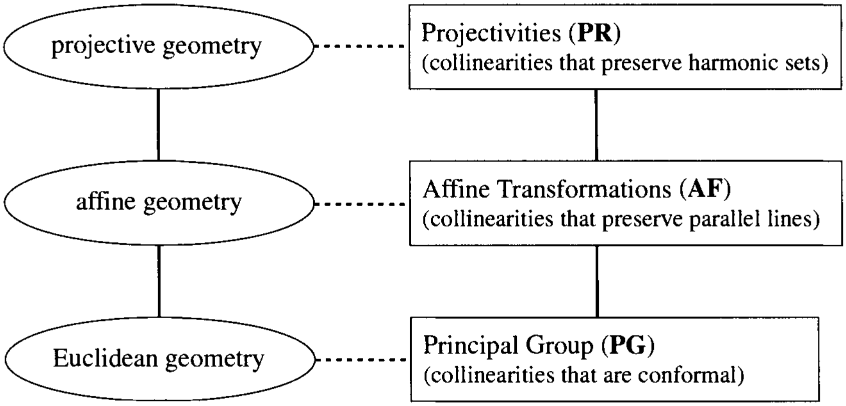
We have seen three transformation groups connected with Klein's Erlangen Program,

$$\mathbf{PG} \subseteq \mathbf{AF} \subseteq \mathbf{PR},$$

and each of these groups leaves different sets of geometric properties invariant (Figure 15.9). Furthermore, the "larger" the group, the more general is its geometry. For instance, since **PG** is a subgroup of **AF**, a model of Euclidean geometry can be interpreted as an affine model but not necessarily conversely. Also, both of these geometries are contained within projective geometry when the line at infinity is included in the plane. We should note that not all geometries fit into Klein's classification scheme. Differential geometry is an example. However, the Erlangen Program directed research for about 50 years and provided a framework in which the relationships between many geometries could be studied (Kline 1972, 920).

Leipzig

After Klein introduced his program in 1872, he remained at the University of Erlangen for four years. Because of his outstanding work, the *Technische Hochschule* in



projective geometry
Projectivities (PR)
(collinearities that preserve harmonic sets)
affine geometry
Affine Transformations (AF)
(collinearities that preserve parallel lines)
Euclidean geometry
Principal Group (PG)
(collinearities that are conformal)

Figure 15.9 A hierarchy of geometries.

Munich offered him a position in the geometry department. As an institution with an outstanding scientific reputation, Klein was happy to accept. He spent several years there but moved on to Leipzig in 1880. At the university he began teaching geometry, set up a mathematical reading room, and taught students how to create mathematical drawings. However, his techniques were not well received by other faculty. Also during this time Klein began a correspondence with Poincaré concerning a mutual field of interest. In an attempt to beat him to results, Klein pushed himself to keep up with Poincaré. All of this stress led to a mental breakdown in 1882. Then in 1885, shortly after Klein had begun to recover from his rivalry with Poincaré, Klein met David Hilbert. At the time, Klein was 36 and Hilbert, 23 (Yaglom 1988, 125–126; Reid 1996, 18; Gray 2007, 225, 279).

Hilbert was born in Wehla near Kant's home town of Königsberg on January 23, 1862. His father was a judge and his mother had an interest in philosophy. Hilbert began school at the gymnasium when he was 8 years old. This was two years later than what was typical, probably because his mother home-schooled him for the first two years. Hilbert did not enjoy his school years because he thought that there was too much memorization. To him this was not interesting. What he did enjoy was mathematics. Hilbert thought the subject was easy because he did not have to memorize the answers. He could always simply figure it out. In the fall of 1880 he began his collegiate life at the University of Königsberg. Although his father wanted him to study law, Hilbert chose the only subject that truly interested him. It was traditional at the time in Germany to study at various schools, but Hilbert left Königsberg for only one semester. He much preferred to remain close to his home. After his coursework was completed, Lindemann, who was then at Königsberg, suggested Hilbert study invariants for his dissertation. He defended on December 11, 1884 (Reid 1996, 1, 3–4, 6–7, 9, 15).

After hearing Hilbert's first presentation at the *Technische Hochschule*, Klein realized that he would become a leading mathematician, so Klein suggested to Hilbert that he should travel to Paris as he had done 15 years earlier. Hilbert left in the early spring of 1886. While in Paris he met many of the leading French mathematicians and wrote back to Klein detailing his time there. He met Jordan, who he thought was a very pleasant person. He also met Poincaré; Hilbert's impression of the mathematician was that he was brilliant but quite shy. He also thought that Poincaré's tremendous output was due partly to his publishing even the smallest of results. Nonetheless, Hilbert benefited from the contacts he made in Paris and from the mathematics that he learned (Reid 1996, 19–20).

Göttingen

In 1886, Klein made the last move of his career. It was to the university of Gauss and Riemann at Göttingen. In June of that year Hilbert returned to Germany and made a stop at Klein's new home to make his last report in person. Hilbert did not stay long but returned to his home in Königsburg. By July he finished his *Habilitationsschrift*, which had been put on hold because of his travels. Hilbert was now a *privatdozent* at his hometown university, and he was pleased about his situation (Reid 1996, 25, 27).

Over the next several years the two mathematicians took different paths. Hilbert pushed ahead with his research. His main field of interest was invariant theory, a subject that Hilbert would eventually exhaust. Klein, on the other hand, had seen the last of his productive years as a mathematician. However, Klein was not the type to be inactive. He threw himself into other projects. For one, he was determined to make the university at Göttingen the leader in mathematical and scientific research. He began by changing the atmosphere of the university. He established a reading room on the third floor of the main hall as he had done in Leipzig. Students were encouraged to spend time there to discuss their work or freely take books from the shelves. In one of the hallways Klein displayed numerous mathematical models. This hall was famous among the students, so much so that they called it the "room of models," despite its being a simple hallway. To complete his plan, Klein then moved to recruit many of the top mathematicians to Göttingen. In 1894 a position opened and Klein made it clear that he wanted Hilbert to fill it. The search committee agreed and Hilbert accepted (Reid 1996, 45–46, 48; Yaglom 1988, 135).

At Göttingen Hilbert continued his mathematical pursuits and taught classes. It was here where the two brilliant mathematicians differentiated themselves from each other in a very public way. Hilbert was of the habit of preparing only broad outlines for his lectures and would then develop the mathematics in front of his students. He would often make errors when working the details, but he did not mind because he was showing his students how a mathematician worked. Hilbert's content was direct and to the point, and he would often repeat himself in an attempt to make sure that all of his students understood. Although some of his colleagues thought that his style was better suited for the gymnasium, most of his students appreciated the "beautiful insights" that they gleamed from the time in his classes.

Klein's approach was different. When it came to his lectures, Klein was a perfectionist. He would arrive at the room an hour early to mentally prepare his presentation. His assistant would have prepared for him a list of references. Klein would check these and use them all. By the time the lecture had started, he had prepared the entire lecture, including all of the formulas and diagrams that were required. By the end the chalkboard would be full of mathematics. Klein believed that he should present only an outline of the topic because he thought that students should spend a good four hours working on the mathematics outside his one-hour lecture (Reid 1996, 48–49).

New Postulates

During the 1898–1899 academic year, Hilbert surprised his students by giving a sequence of lectures on geometry. They had known him as an expert in invariant theory or his newfound interest of number theory, but not in geometry. Hilbert did have experience in the subject and had attended lectures on modern viewpoints that went beyond Lobachevski, Poncelet, and Riemann. Although inspired by their work, contemporary mathematicians such as Moritz Pasch had reduced the subject to pure logic, and the mathematician Giuseppe Peano took Pasch's work and translated it into his new symbolic notation. Essentially, in their hands geometry had become an abstract study not of points and lines but of sets of any kind that obeyed certain rules. Although Hilbert agreed with this new view, he realized that the new notation made it hard to grasp. Hilbert solved the problem by using the old Euclidean vocabulary when dealing with the new abstractions. The terms *point* and *line* simply became names for the objects and remain undefined. These objects could be anything as long as they could be interpreted to obey the postulates. Hilbert once clarified this viewpoint by stating that

> [o]ne must be able to say at all times — instead of points, straight lines, and planes — tables, chairs, and beer mugs.

Nonetheless, the familiar terms of *line* and *point* were preferred because they served as a mnemonic device for his students, making the new viewpoint easier to learn (Reid 1996, 57, 59, 61; Boyer and Merzbach 1991, 608).

Hilbert then took his geometric understanding to its logical conclusion. If the words *point* and *line* were going to be reexamined, why should not the same be done to Euclid's entire geometry? Despite his *Elements* remaining at the center of mathematics for over two millennia, Euclid's work was not without critiques. Gauss observed that Euclid had assumed betweenness properties in his proofs, and Leibnitz noted that he had assumed continuity. Neither of these are surprising when geometric proofs rely heavily on diagrams. Both betweenness and continuity are easily assumed from pictures. There is nothing wrong with these assumptions. The problem was that Euclid did not include them among his postulates.

To remedy matters, Hilbert introduced a new set of postulates and then proceeded to reprove the basic results of the first book of the *Elements*. As was standard, the number of postulates should be as few as possible, but they need not be self-evident because the terms *point* and *line* could represent anything. Nonetheless, the sentences chosen should use familiar terminology. More importantly, the postulate set must satisfy three criteria:

- The set must be independent.
- The set must be consistent.
- The set must be complete.

Although we saw the concepts of independence and consistency as early as Saccheri's work, Hilbert is responsible for making these criteria desirable for all modern axiom sets (Kline 1972, 102; Reid 1996, 63–64).

These were the ideas that Hilbert introduced to his students. His lectures became the basis for his *Foundations of Geometry*. It begins with these words,

> Geometry, like arithmetic, requires only a few and simple principles for its logical development. These principles are called the **axioms** of geometry. The establishment of the axioms of geometry and the investigation of their relationships is a problem which has been treated in many excellent works of the mathematical literature since the time of Euclid. This problem is equivalent to the logical analysis of our perception of space. (Hilbert 1992, 2)

Hilbert then begins to set up his system. He takes two types of objects. He called them **points** and **lines**. Denote points by uppercase Latin letters and lines by lowercase Latin letters. The points and lines exist in a **plane**.

When describing relationships among points and lines, it is common to use such words as **lie**, **between**, and **congruent**. For example,

- The point P *lies* on the line l.
- The point A is *between* the points B and C.
- The segments $\overline{AB}$ and $\overline{CD}$ are *congruent*.

These relationships will also be undefined, yet we will have some initial information about them because the axioms will codify our intuition concerning these relationships. The **incidence axioms** will explain *lie*, the **order axioms** will explain *between*, and the **congruence axioms** will explain *congruent*. There are two more sets of axioms: the singleton **parallel axiom**, which is a proposition equivalent to Euclid's Parallel Postulate, and the **continuity axioms**, which identify the principles that prevent Euclidean geometry from being discrete.

The incidence axioms determine what it means for one geometric object to lie on, pass through, intersect, or join another object (Hilbert 1992, 3–4). Compare them with the projective postulates of Sections 9.2 and 14.1.

■ **AXIOMS 15.5.1 [Incidence, *Foundations* §2]**

1. For every two points A and B, there exists a line l that contains each of the points A and B.
2. For every two points A and B, there exists no more than one line that contains each of the points A and B.
3. There exists at least two points on a line. There exist at least three points that do not lie on a line.

It is interesting that Hilbert stated the first two incident axioms as separate statements instead of combining them into one. However, it is reasonable to state the results as he did. Although we have not seen any geometry that does not satisfy the first, there is a model of the elliptic geometry of Riemann that does not satisfy the second (Section 13.4). However, both axioms together quickly yield the expected result.

■ **THEOREM 15.5.2**

For every two points A and B, there exists exactly one line that contains each of the points A and B.

Notice that $\mathbb{R}^2$ satisfies the Incidence Axioms, but there are other significantly smaller models that do the same thing. By Axiom 15.5.1.3 we arrive at a minimum of three points, A, B, and C. Axiom 15.5.1.1 guarantees that we have $\overline{AB}$, $\overline{AC}$, and $\overline{BC}$. If these are all the same line, then by Axiom 15.5.1.3, there exists at least three more points. However, it may be the case that $\overline{AB}$ and $\overline{AC}$ are different lines, so that the same axioms requires only two extra points, say D and E. Hence, only five points are required to satisfy Axioms 15.5.1.1 to 15.5.1.3. This is illustrated by the model

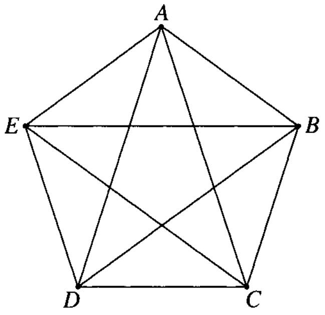


Figure 15.10 A finite model for the Incidence Axioms.

shown in Figure 15.10. Although the segments found inside the pentagon appear to intersect, they do not. Segments in this model intersect only at the points labeled.

The order axioms give meaning to the word *between*. We will write A–B–C to mean that B lies between A and C.

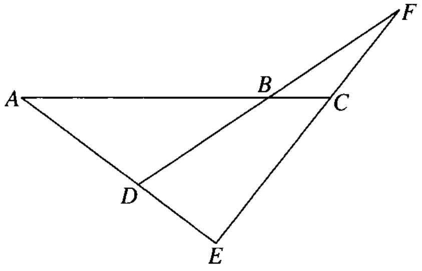
■ AXIOMS 15.5.3 [Order, *Foundations* §3]

1. If A–B–C, the points A, B, and C are three distinct points lying on a line, and C–B–A.
2. For two points A and B, there is a point C on $\overline{AB}$ produced such that A–B–C.
3. Of any three points on a line, there exists no more than one that lies between the other two.
4. **[Pasch]** In $\triangle ABC$, if a line intersects $\overline{AB}$ in a point D such that $A - D - B$, the line also intersects exactly one of the other sides in a point E such that either $A - E - C$ or $B - E - C$.

The order axioms allow us to conclude that points on lines behave as we expect

■ THEOREM 15.5.4 [*Foundations* §4.3]

For any two points A and C, there exists a point B on $\overline{AC}$ such that A–B–C.



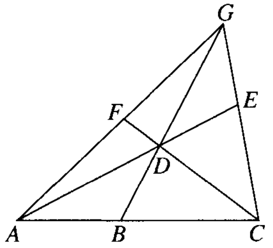
PROOF

Suppose that A and C are two points. Let D be a point not on $\overline{AC}$ by Axiom 15.5.1.3. Appealing to Axiom 15.5.3.2, we know that there is a point E such that A–D–E, and by the same axiom there is a point F such that E–C–F. If $\overline{DF}$ intersected $\overline{EC}$, Axiom 15.5.1.2 would be violated. Hence, $\overline{DF}$ intersects side $\overline{AC}$ at a point B by Pasch's Axiom (15.5.3.4). ■

If points A, B, and C are collinear, Axiom 15.5.3.3 prevents us from writing any two of A–B–C, B–A–C, or A–C–B at the same time, but none of the axioms state that one of these options must hold. Instead, this is a theorem. Its proof is important to read very carefully. Do not rely on results that seem to appear in the diagram but have yet to be proven.

■ THEOREM 15.5.5 [*Foundations* §4.4]

Of any three collinear points A, B, and C, there exists one that lies between the other two.



PROOF

Suppose that neither B–A–C nor A–C–B. Take D not on $\overline{AC}$ and find G such that B–D–G (Axioms 15.5.1.3 and 15.5.3.2). Using Pasch's Axiom (15.5.3.4) on $\triangle BCG$, it follows that $\overline{AD}$ intersects $\overline{GC}$ at E, where G–E–C. Notice that at the moment that we do not know if A–D–E. By a similar argument, $\overline{DC}$ intersects $\overline{AG}$ at F with A–F–G. Furthermore, it is still a question whether F–D–C.

Now apply Pasch's Axiom to $\triangle FGC$ using $\overline{AE}$. Since this line intersects $\overline{GC}$ at E and it is impossible for it to intersect $\overline{FG}$ (Axiom 15.5.1.2), we see that $\overline{AE}$ must intersect $\overline{FC}$. Since already $\overline{AE}$ meets $\overline{FC}$ at D, this point must be the point given by Pasch's Axiom. Hence, F–D–C. But, applying this same argument to $\triangle AFC$ with $\overline{DG}$ intersecting $\overline{FC}$ at D, we find that A–B–C. ■

Although the Incidence Axioms can be satisfied by a finite model, that is not the case for the Order Axioms. By a sequence of applications of Theorem 15.5.4, we may prove the next result.

■ THEOREM 15.5.6 [*Foundations* §4.6]

Between any two points on a line there exists a countably infinite number of points.

The next set of axioms deal with the familiar concept of congruence. Euclid wrote none of these as postulates in the *Elements*, but he used them all.

■ **AXIOMS 15.5.7 [Congruence, *Foundations* §5]**

1. If A and B are points on a line l, and A' is a point on the same or on another line l', there exists a point B' on a given side of the line that contains B' such that $\overline{AB} \cong \overline{A'B'}$.
2. If $\overline{A'B'} \cong \overline{AB}$ and $\overline{A''B''} \cong \overline{AB}$, then $\overline{A'B'} \cong \overline{A''B''}$.
3. On the line l, let $\overline{AB}$ and $\overline{BC}$ have no points in common other than B. On a line l' that may or may not be the same line as l, let $\overline{A'B'}$ and $\overline{B'C'}$ have no points in common other than B'. In this case, if $\overline{AB} \cong \overline{A'B'}$ and $\overline{BC} \cong \overline{B'C'}$, then $\overline{AC} \cong \overline{A'C'}$.
4. For any $\sphericalangle ABC$ and $\overline{B'A'}$, there exists a unique $\overline{B'C'}$ on a given side of $\overline{B'A'}$ such that $\sphericalangle ABC \cong \sphericalangle A'B'C'$. Moreover, every angle is congruent to itself.
5. In $\triangle ABC$ and $\triangle A'B'C'$, if
$$\overline{AB} \cong \overline{A'B'},\ \overline{AC} \cong \overline{A'C'}, \text{ and } \sphericalangle BAC \cong \sphericalangle B'A'C',$$
then $\sphericalangle ABC \cong \sphericalangle A'B'C'$.

Hilbert concluded his axiom set by including propositions that are required to make the Euclidean plane have the properties that we expect. That is, the plane should have parallel lines and be continuous. Hilbert accomplished this by including Archimedes' Postulate (6.2.1) and by returning to the definition of parallel used by Euclid. Instead of using the ancient version of the Parallel Postulate, Hilbert chose a modified version of Playfair's Postulate (10.1.1).

■ **DEFINITION 15.5.8**

Two lines are **parallel** if they do not intersect.

■ **AXIOM 15.5.9 [Euclid]**

If l is any line and P a point not on l, then there exists at most one line that passes through P and is parallel to l.

The Model

To show that Hilbert's axioms for Euclidean geometry are consistent, we must find a model in which the axioms can be interpreted as true statements. Because of Theorem 15.5.6, the model must be infinite. A suitable chosen set of rational numbers will suffice, but along with Hilbert we will choose the Cartesian plane $\mathbb{R}^2$.

We interpret the undefined terms *point*, *line*, *incident*, *between*, and *congruent* as follows:

- A *point* is an element of $\mathbb{R}^2$.
- A *line* is an element of $\mathscr{L} = \{[u, v, w] : u, v, w \in \mathbb{R}\}$.
- The point (x, y) is *incident* with line $[u, v, w]$ if and only if
$$ux + vy + w = 0.$$
- The point (x_2, y_2) is *between* (x_1, y_1) and (x_3, y_3) if and only if all three points are different and there exists a line on which all three points are incident and
$$\text{either } x_1 \leqslant x_2 \leqslant x_3 \text{ or } x_1 \geqslant x_2 \geqslant x_3, \text{ and}$$
$$\text{either } y_1 \leqslant y_2 \leqslant y_3 \text{ or } y_1 \geqslant y_2 \geqslant y_3.$$
- $\overline{AB}$ is *congruent* to $\overline{A'B'}$ if and only if there exists an isometry ϕ such that $\phi[\overline{AB}] = \overline{A'B'}$, where for every two points A and B,
$$\overline{AB} = \{C : A - C - B\}.$$
- $\sphericalangle ABC$ is *congruent* to $\sphericalangle A'B'C'$ if and only if there exists a similarity ψ such that $\psi[\sphericalangle ABC] = \sphericalangle A'B'C'$. An angle in the model is two line segments that share exactly one endpoint and are produced indefinitely in one direction.

Call $\mathbb{R}^2$ with these interpretations the **Cartesian model** of Euclidean geometry. To illustrate these interpretations, observe the following:

- $(0, 1)$ is incident with $[2, 4, -4]$ because $(0, 1)$ is a solution to $2x+4y-4 = 0$.
- $(0, 4)$ is between $(0, 1)$ and $(0, 5)$ because these points are on $[1, 0, 0]$, $0 \leqslant 0 \leqslant 0$, and $1 \leqslant 4 \leqslant 5$.
- The line segment with endpoints $(1, 2)$ and $(-3, 5)$ is congruent to the line segment with endpoints $(3, -1)$ and $(-1, 2)$ because the second segment is the image of the first under the translation described by $\langle 2, -3\rangle$.

We will check that some of the axioms hold true under this interpretation and leave the rest for Exercise 5. We begin with an incidence axiom.

> *For every two points A and B, there exists a line l that contains each of the points A and B.*

Let $A = (x_1, y_1)$ and $B = (x_2, y_2)$. Using some basic algebra, we find that
$$y - y_1 = \frac{y_2 - y_1}{x_2 - x_1}(x - x_1).$$
Therefore,
$$(y_1 - y_2)x + (x_2 - x_1)y + x_1y_2 - x_2y_1 = 0,$$
which means that both A and B are on $[y_1 - y_2, x_2 - x_1, x_1y_2 - x_2y_1]$.

Next we examine an axiom of order.

> *For two points A and B, there is a point C on $\overline{AB}$ produced such that A–B–C.*

Let $A = (x_1, y_1)$ and $B = (x_2, y_2)$. We already know that these points are on $[y_1 - y_2, x_2 - x_1, x_1y_2 - x_2y_1]$. There are many cases to consider when finding C. For example, if $0 \leqslant x_1 \leqslant x_2$ and $0 \leqslant y_1 \leqslant y_2$, then

$$C = (2x_2 - x_1, 2y_2 - y_1)$$

is on the line and $A - B - C$ because

$$x_1 \leqslant x_2 \leqslant 2x_2 - x_1$$

and

$$y_1 \leqslant y_2 \leqslant 2y_2 - y_1.$$

Finally, we check a congruence axiom.

> *On the line l, let $\overline{AB}$ and $\overline{BC}$ have no points in common other than B. On a line l' that may or may not be the same line as l, let $\overline{A'B'}$ and $\overline{B'C'}$ have no points in common other than B'. In this case, if $\overline{AB} \cong \overline{A'B'}$ and $\overline{BC} \cong \overline{B'C'}$, then $\overline{AC} \cong \overline{A'C'}$.*

Let $A - B - C$ on l and $A' - B' - C'$ on l'. Assume that $\overline{AB} \cong \overline{A'B'}$ and $\overline{BC} \cong \overline{B'C'}$. Under our interpretation, this means that there exist isometries ϕ and ψ such that

$$\phi[\overline{AB}] = \overline{A'B'} \text{ and } \psi[\overline{BC}] = \overline{B'C'}.$$

Using these two functions, we define

$$\eta(X) = \begin{cases} \phi(X) & \text{if } A - X - B \text{ or } X = A \text{ or } X = B \\ \psi(X) & \text{if } B - X - C \text{ or } X = C. \end{cases}$$

This is the isometry desired.

The models of the hyperbolic and elliptic geometries show that these new systems are consistent if Euclidean geometry is consistent. By using the Cartesian plane as a model of his axioms, Hilbert showed that Euclidean geometry is consistent if arithmetic is consistent. Since mathematicians had little doubt concerning the consistency of arithmetic, Hilbert succeeded in putting all of the geometries on a solid logic footing.

Final Note

Lie, who had been a professor of mathematics at Christiania University, took Klein's place at Leipzig by Klein's recommendation. Three years later, in 1898, Lie received the first International Lobachevski Prize for his geometric work. The prize was established by the Kazan society in 1893 to celebrate the 100th anniversary of

Lobachevski's birth. Later winners would include Klein and Poincaré. In 1898, Lie returned to his home in Norway, and he died the following year on February 18, 1899 (Yaglom 1988, 126–130).

In 1872, Klein began assisting the editors of the journal *Mathematische Annalen* and became its chief editor in 1876. As was typical for Klein, he was instrumental in earning the journal its reputation as the leading mathematical journal. In 1898 he led the team whose task was to published Gauss's collected works. They finished in 1918. His other ventures included the publication of his own books and the lecture notes from the classes he taught at Göttingen (Yaglom 1988, 132–134).

Influenced by his childhood days at the Düsseldorf gymnasium, days that he did not remember with fondness, Klein led efforts to reform the teaching of mathematics. Himself known to be an excellent teacher, in 1898 he organized the International Commission on Mathematics Education. The commission recommended numerous changes that we see still today in the mathematics classroom:

- The use of visual aids
- The emphasis on the study of functions in algebra
- The application of geometric transformations in geometry
- A more unified approach to various mathematical subjects
- A closer connection between mathematics and science education

Such activities, combined with his academic accomplishments, led to his being the representative for Göttingen University in the upper house of the Prussian parliament (Yaglom 1988, 136–137).

Klein lived out his days in Göttingen and died on July 22, 1925 (Yaglom 1988, 137). Under Klein's leadership the university had risen from the mediocrity that Riemann encountered to being a preeminent institute for mathematics. He left the university in good hands. Not only did Hilbert remain to carry on the tradition, but there were other notable mathematicians, including Paul Bernays, Richard Courant, Edmund Landau, Emmy Noether, and Hermann Weyl, in addition to Max Born and James Franck in physics. In 1932, Hilbert celebrated his seventieth birthday, and the next year saw the beginning of the end of what Klein had established at Göttingen (Reid 1996, 191, 203–204).

Exercises

1. Show that the following axiom sets are independent.
   (a) Incidence axioms (15.5.1)
   (b) Order axioms (15.5.3)
   (c) Congruence axioms (15.5.7)
2. Which of Hilbert's axioms can be shown to be consistent with a finite model?
3. Identify all pairs of parallel lines in Figure 15.10.

4. Prove that Hilbert's geometry contains infinitely many lines.

5. Show that Hilbert's axioms hold in the Cartesian model.

6. Prove that congruence of line segments is an equivalence relation.

7. How would we show that a set of axioms is complete?

8. Use Hilbert's concept of betweenness to define the interior and exterior of an angle.

9. Define what it means for two points to be on opposite sides of a line segment. What would it mean for two points to be on the same side of a line segment?

10. Prove the following from Hilbert's *Foundations of Geometry*. Assume the standard definitions for all defined terms.

- (a) For any two points A and B, there exists C collinear with A and B such that C is between A and B.
- (b) Of any three distinct collinear points, there exists one the is between the other two.
- (c) The base angles of an isosceles triangle are congruent.
- (d) SAS
- (e) ASA
- (f) Let $\sphericalangle ABC$ be the supplement of $\sphericalangle CBD$ and $\sphericalangle A'B'C'$ the supplement of $\sphericalangle C'B'D'$. If $\sphericalangle ABC \cong \sphericalangle A'B'C'$, then $\sphericalangle CBD \cong \sphericalangle C'B'D'$.
- (g) Vertical angles are congruent.
- (h) Let $\overline{BD}$ be in the interior of $\sphericalangle ABC$ and $\overline{B'D'}$ be in the interior of $\sphericalangle A'B'C'$. If $\sphericalangle DBC \cong \sphericalangle D'B'C'$ and $\sphericalangle ABC \cong \sphericalangle A'B'C'$, then $\sphericalangle ABD \cong \sphericalangle A'B'D'$.
- (i) If two points A and C are put on different sides of $\overline{BD}$ and if $\overline{AD} \cong \overline{CD}$ and $\overline{BA} \cong \overline{BC}$, then $\sphericalangle ABD \cong \sphericalangle CBD$.
- (j) SSS
- (k) If $\sphericalangle A' \cong \sphericalangle A$ and $\sphericalangle A'' \cong \sphericalangle A$, then $\sphericalangle A' \cong \sphericalangle A''$.
- (l) All right angles are congruent to each other.
- (m) The exterior angle of a triangle is greater than any interior angle that is not adjacent to it.
- (n) In every triangle the greater angle lies opposite the greater side.
- (o) A triangle with two congruent angles is isosceles.
- (p) AAS
- (q) Every segment can be bisected.

2.3.4. Projective curves.

2.3.4.1. THE PROJECTIVE PLANE. We define the projective plane to be the set

$$\mathbb{P}_2 := \{\text{1-dimensional subspaces of } \mathbb{C}^3\}.$$

If $(x, y, z) \in \mathbb{C}^3 - \{0\}$ then there is a unique line in $\mathbb{C}^3$ passing through (x, y, z) and $(0, 0, 0)$. We denote this point of $\mathbb{P}_2$ by

$$[x, y, z].$$

We define the topology on $\mathbb{P}_2$ to be the coarsest topology such that the map $\pi : \mathbb{C}^3 - \{0\} \to \mathbb{P}_2$ sending (x, y, z) to $[x, y, z]$ is continuous. That is to say, a set $U \subset \mathbb{P}_2$ is open if and only if $\pi^{-1}(U)$ is open in $\mathbb{C}^3$.

Chapter 12

Euclidean Space Tangent at a Point

63. Euclidean tangent metric. Consider a Riemannian manifold defined as a manifold endowed with an arbitrary line element

$$ds^2 = g_{ij} du^i du^j. \tag{12.1}$$

We shall assume that the right-hand side of (12.1) is a positive definite differential form with coefficients g_{ij} of class C^1.

The metric defined by a Euclidean line element

$$d\sigma^2 = \gamma_{ij} du^i du^j \tag{12.2}$$

constructed with variables u^i is called a *Euclidean tangent to the metric* (12.1) at the point $A(u_0^1, \dots, u_0^n)$ if we have $\gamma_{ij} = g_{ij}$ for $u^i = u_0^i$.

Obviously, there exists an infinity of Euclidean metrics tangent to the metric (12.1) at a given point. In order to show this, it is sufficient, for example, to take

$$\gamma_{ij} = (g_{ij})_0.$$

On the other hand, the set of all these metrics does not depend on the choice of coordinates defining the Riemannian manifold analytically, since under the change of the variables u^i by certain other determined variables v^i, the new values at the point A of the coefficients of the line element only depend on their original values at A. Therefore, the equality $\gamma_{ij} = g_{ij}$ remains valid also for the new variables at the point A.

Rather than saying that we endow the manifold in question with a new (Euclidean) metric, we can say that we represent a Riemannian manifold in the Euclidean space in such a way that in this representation the line element of the Euclidean space becomes $d\sigma^2$. This Euclidean space is called the *Euclidean space tangent at the point A to the given Riemannian manifold.* This terminology is convenient since it provides a visualization.

We can say that there exists an infinity of Euclidean spaces tangent at the point A to a Riemannian manifold in the sense that the line element $d\sigma^2$ depends on an infinite number of arbitrary parameters. However, as we are going to consider in the sequel only geometric properties common to all these spaces, we may quite conveniently say, *the Euclidean space tangent at the point A to the Riemannian manifold.*

64. Tangent Euclidean space. The first geometric notion implied by consideration of the tangent Euclidean space is that of the distance between a point A and a point infinitesimally close to A. The distance is equal to $d\sigma$ or ds. It is the same notion on which the definition of a Riemannian manifold is based.

1°. *The angle between the two directions du^i and δu^i.* In the tangent Euclidean space, the value of the cosine of the angle between two vectors $\mathbf{X}$ and $\mathbf{Y}$ is obtained from the scalar product $\mathbf{X}\cdot\mathbf{Y}$ which coincides with the coefficient of 2λ in the decomposition of the square of the sum $\mathbf{X}+\lambda\mathbf{Y}$:

$$(\mathbf{X}+\lambda\mathbf{Y})^2 = \mathbf{X}^2 + 2\lambda\mathbf{X}\cdot\mathbf{Y} + \lambda^2\mathbf{Y}^2.$$

In the Riemannian manifold one must consider the product

$$\begin{aligned} g_{ij}\ &(du^i + \lambda\delta u^i)(du^j + \lambda\delta u^j) \\ &= g_{ij}(du^i du^j + \lambda^2 \delta u^i \delta u^j) + 2\lambda g_{ij} du^i \delta u^j. \end{aligned}$$

Thus, the required cosine of the angle between two vectors $\mathbf{X}$ and $\mathbf{Y}$ is

$$\cos\varphi = \frac{g_{ij}du^i du^j}{ds\,\delta s}. \tag{12.3}$$

We can be sure in advance that *the right-hand side of this equation does not depend on the choice of a coordinate system*, since the angle between two directions in the tangent Euclidean space with the metric $d\sigma^2$ is determined by the same formula.

Likewise one may define the angle between a p-dimensional plane element and a q-dimensional plane element, etc., if they have a common vertex.

2°. We apply the notion of the angle between directions at a point of a Riemannian manifold in order to obtain the *rectangular coordinates in an orthogonal frame.*

As is known, a positive definite form

$$ds^2 = g_{ij}du^i du^j$$

can be always represented as a sum of squares:

$$ds^2 = (\omega^1)^2 + (\omega^2)^2 + \ldots + (\omega^n)^2, \tag{12.4}$$

where

$$\left\{ \begin{array}{l} \omega^1 = a_1^1 du^1 + a_2^1 du^2 + \ldots + a_n^1 du^n, \\ \cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots \\ \omega^n = a_1^n du^1 + a_2^n du^2 + \ldots + a_n^n du^n. \end{array} \right. \qquad \det(a_i^j) \neq 0,$$

Consider now vectors $\mathbf{I}_i$ in the tangent Euclidean space, whose coordinates X^k satisfy the equations

$$\text{for } \mathbf{I}_1: \quad \begin{cases} a_1^1 X^1 + \ldots + a_n^1 X^n = 1, \\ a_1^2 X^1 + \ldots + a_n^2 X^n = 0, \\ \dots\dots\dots\dots\dots\dots\dots\dots \\ a_1^n X^1 + \ldots + a_n^n X^n = 0; \end{cases}$$

. . . .

$$\text{for } \mathbf{I}_n: \quad \begin{cases} a_1^1 X^1 + \ldots + a_n^1 X^n = 0, \\ a_1^2 X^1 + \ldots + a_n^2 X^n = 0, \\ \dots\dots\dots\dots\dots\dots\dots\dots \\ a_1^n X^1 + \ldots + a_n^n X^n = 1. \end{cases}$$

The expression in the numerator of formula (12.3) is a bilinear form associated with the quadratic form in (12.1). After reduction, the quadratic form in (12.1) takes the form (12.4). Then the bilinear form in the numerator of (12.3) becomes

$$\omega^1(d)\,\omega^1(\delta) + \ldots + \omega^n(d)\,\omega^n(\delta), \tag{12.5}$$

where

$$\omega^i(d) = a_k^i du^k, \quad \omega^i(\delta) = a_k^i \delta u^k.$$

Consider two vectors $\mathbf{I}_1$ and $\mathbf{I}_2$. For the first vector $\mathbf{I}_1$, we have

$$\frac{\omega^1(d)}{dt} = 1, \quad \omega^2(d) = 0, \quad \ldots, \quad \omega^n(d) = 0,$$

and for the second, we have

$$\omega^i(\delta) = 0, \quad \frac{\omega^2(\delta)}{\delta t} = 1, \quad \ldots, \omega^2(\delta) = 0.$$

Substituting these values into bilinear form (12.5), we see that this form vanishes. Thus, the vectors $\mathbf{I}_1$ and $\mathbf{I}_2$ are orthogonal (cf. No. **38**). The remaining identities

$$\mathbf{I}_j \cdot \mathbf{I}_k = \delta_{jk}$$

can be proved in a similar way. Thus, the frame constructed on the n vectors $\mathbf{I}_i$ in the tangent Euclidean space is orthonormal. The components of translations of this frame are the same forms ω^i that were used in the frame definition.

3°. At the point A of the Euclidean tangent space, one can define *vectors* (in an oblique frame, covariant and contravariant), *bivectors, multivectors*, and generally speaking, arbitrary *tensors*. All these can be extended to a Riemannian manifold. Moreover, we can introduce notions concerning the entire curve or the entire surface.

Firstly, since the infinitesimal distance between two infinitesimally close points is known, by means of addition (integration), we obtain the arc length of any curve,

$$s = \int \sqrt{\sum_i (\omega^i)^2}$$

This implies immediately (an idea due to Riemann) the notion of a *straight line*, or *geodesic* as giving an extreme for the distance. Here we merely indicate this possibility in order to return to it later.

Secondly, as is known, the elementary volume of the manifold is defined by the formula

$$d\tau = \omega^1 \wedge \omega^2 \wedge \ldots \wedge \omega^n.$$

65. The main notions of vector analysis. Given a vector field in a Riemannian manifold, it is not yet possible to define the derivative tensor, since, for this, one needs to be able to compare tensors at different points of the manifold. Nevertheless, we can define the gradient of a function and the *curl* of a vector field. For example, consider a scalar field. Let V be a function of a point,

$$V = V(u^1, \ldots, u^n).$$

The differential dV depends linearly on $du^1, du^2, \ldots, du^n$. Thus, this differential can be represented in the form

$$dV = V_1\omega^1 + V_2\omega^2 + \ldots + V_n\omega^n. \tag{12.6}$$

The quantities V_i define the *gradient* of the function V.

Next, consider a field of vectors

$$(X_1, X_2, \ldots, X_n).$$

The tangent tensor form is

$$\widetilde{\omega} = X_1\omega^1 + \ldots + X_n\omega^n.$$

Compute its exterior differential. Since the differential of X is linearly expressed in terms of ω^i, we have

$$d\widetilde{\omega} = X_{ij}\omega^i \wedge \omega^j, \tag{12.7}$$

where X_{ij} is the skew-symmetric tensor called the *curl* of the vector field.

For example, for the expression

$$\widetilde{\omega} = X dx + Y dy + Z dz,$$

the exterior differential is

$$\begin{aligned}
&dX \wedge dx + dY \wedge dy + dZ \wedge dz \\
&= \frac{\partial X}{\partial y} dy \wedge dx + \frac{\partial X}{\partial z} dz \wedge dx + \frac{\partial Y}{\partial x} dx \wedge dy \\
&\quad + \frac{\partial Y}{\partial z} dz \wedge dy + \frac{\partial Z}{\partial x} dx \wedge dz + \frac{\partial Z}{\partial y} dy \wedge dz \\
&= \left(\frac{\partial Z}{\partial y} - \frac{\partial Y}{\partial z}\right) dy \wedge dz + \left(\frac{\partial X}{\partial z} - \frac{\partial Z}{\partial x}\right) dz \wedge dx + \left(\frac{\partial Y}{\partial x} - \frac{\partial X}{\partial y}\right) dx \wedge dy,
\end{aligned}$$

i.e., we obtain the usual form of the curl in the Euclidean space.

We also derive the *divergence*. The flux of a vector field defines the tensor form

$$\widetilde{\omega} = X_1 \omega^2 \wedge \omega^3 + X_2 \omega^3 \wedge \omega^1 + X_3 \omega^1 \wedge \omega^2,$$

where the exterior products $\omega^i \wedge \omega^j$ define certain areas.

The exterior differential has the form

$$d\widetilde{\omega} = a\, \omega^1 \wedge \omega^2 \wedge \omega^3.$$

Here, a is the *divergence* of the vector field.

If we take the flux of the gradient,

$$V_1 \omega^2 \wedge \omega^3 + V_2 \omega^3 \wedge \omega^1 + V_3 \omega^1 \wedge \omega^2, \tag{12.8}$$

and apply exterior differentiation, then we obtain the second differential parameter

$$\Delta_2 V \omega^1 \wedge \omega^2 \wedge \omega^3.$$

EXAMPLE. Consider the line element

$$ds^2 = z^2 dx^2 + z^2 dy^2 + dz^2.$$

Here we have

$$\omega^1 = z\, dx, \quad \omega^2 = z\, dy, \quad \omega^3 = dz.$$

How can we find the second differential parameter?

In order to find the gradient, we differentiate V:

$$\begin{aligned}
dV &= \frac{\partial V}{\partial x} dx + \frac{\partial V}{\partial y} dy + \frac{\partial V}{\partial z} dz \\
&= V_1 \omega^1 + V_2 \omega^2 + V_3 \omega^3 = V_1 z\, dx + V_2 z\, dy + V_3\, dz.
\end{aligned}$$

Thus,

$$V_1 = \frac{1}{z} \frac{\partial V}{\partial x}, \quad V_2 = \frac{1}{z} \frac{\partial V}{\partial y}, \quad V_3 = \frac{\partial V}{\partial z}.$$

These expressions are the components of the gradient. The elementary vector flux is

$$\begin{aligned} &V_1\,\omega^2\wedge\omega^3 + V_2\,\omega^3\wedge\omega^1 + V_3\,\omega^1\wedge\omega^2 \\ &= \frac{\partial V}{\partial x}\,dy\wedge dz + \frac{\partial V}{\partial y}\,dz\wedge dx + \left(z^2\frac{\partial V}{\partial z}\right) dx\wedge dy. \end{aligned}$$

Applying exterior differentiation, we find that

$$\begin{aligned} &\Delta_2 V\,\omega^1\wedge\omega^2\wedge\omega^3 = \Delta_2 V z^2 dx\wedge dy\wedge dz \\ &= \frac{\partial^2 V}{\partial x^2}\,dx\wedge dy\wedge dz + \frac{\partial^2 V}{\partial y^2}\,dy\wedge dz\wedge dx + \left(z^2\frac{\partial V}{\partial z}\right) dz\wedge dx\wedge dy, \end{aligned}$$

i.e., the second differential parameter is

$$\Delta_2 V = \frac{1}{z^2}\left(\frac{\partial^2 V}{\partial x^2} + \frac{\partial^2 V}{\partial y^2} + \left(z^2\frac{\partial V}{\partial z}\right)\right). \tag{12.9}$$

The function V is harmonic in this Riemannian manifold if $\Delta_2 V = 0$.

66. Three methods of introducing a connection. Although we were able to extend many notions from the tangent Euclidean space to a Riemannian manifold, there still remain many basic elementary notions that are missing: for example, we need to define the notion of an angle of rotation of a vector field when we move from one point of the manifold to another one.

In general, every geometric notion involving a *scalar* at any point can be generalized easily. The same can be said about a notion involving one vector or several vectors *provided that they have the same initial point.*

It seems as if the divergence of a vector field is an exception. However, in fact, *the elementary vector flux introduces a field at only one point.*

Summarizing, we see that until now a Riemannian manifold was for us a *collection of small pieces of the Euclidean space.* In some sense it was *amorphous,* since we have not yet connected these different pieces in a mutual orientation. Toward this end, we must define the rotation of a frame under a displacement of a point in the manifold. This can be done by different methods.

Riemann began with the postulate according to which a geodesic of the space, an extreme for the arc length, is not only the shortest line but also is the straightest line, i.e., it does not rotate a frame.

Another method is the same one that led us to the Euclidean tangent space: distinguishing an osculating Euclidean metric and extending its connection to a Riemannian manifold.

The third method is axiomatic: combining more or less natural requirements. This may be the most interesting method, since it admits a generalization to spaces with other fundamental groups.

Here we outline the second and the third methods.

67. Euclidean metric osculating at a point. A Euclidean metric osculating a given metric at a point $A(u_0^i)$ is defined by the line element

$$d\sigma^2 = \gamma_{ij} du^i du^j,$$

provided that the coefficients γ_{ij} and their first-order partial derivatives have the same numerical values at the point $A(u_0^i)$ as they have for the given line element.

The existence of osculating Euclidean metrics does not depend on the choice of coordinate system, since for a given change of variables, the new numerical values of the coefficients g_{ij} and their first-order partial derivatives are completely determined if the original values of the same quantities are known. Thus, rather than speak of an osculating Euclidean metric, we would rather say an *osculating Euclidean space.*

First, it is necessary to prove the existence of osculating Euclidean spaces at a given point A of Riemannian manifold.

From formulas (1.9), (1.10), and (5.4) for an oblique frame in the Euclidean space, we have

$$\begin{cases} d\mathbf{M} = \omega^i \mathbf{e}_i, \\ d\mathbf{e}_i = \omega_i^k \mathbf{e}_k, \quad \omega_i^k = \gamma_i{}^k{}_j \omega^j, \end{cases} \tag{12.10}$$

$$g_{ij} = \mathbf{e}_i \cdot \mathbf{e}_j, \quad dg_{ij} = \omega_i^k g_{kj} + \omega_j^k g_{ik}. \tag{12.11}$$

If we choose the so-called *natural frame*, i.e., if we set

$$\omega^i = du^i, \tag{12.12}$$

then

$$d\omega^i = 0,$$

and the first structure equation (II) of No. **26** implies that

$$du^j \wedge \omega_j^i = 0.$$

It follows from these equations that

$$\omega_j^i = \Gamma_j{}^i{}_k du^k, \quad \Gamma_j{}^i{}_k = \Gamma_k{}^i{}_j, \tag{12.13}$$

$$dg_{ij} = (\Gamma_j{}^i{}_h g_{kj} + \Gamma_j{}^i{}_h g_{ik}) du^k. \tag{12.14}$$

This implies immediately that

$$\frac{\partial g_{ij}}{\partial u^l} = \Gamma_i{}^k{}_l g_{kj} + \Gamma_j{}^k{}_l g_{ik}. \tag{12.15}$$

Thus, if at the point $u^i = u_0^i$, the quantities γ_{ij} coincide with $(g_{ij})_0$, and the coefficients $\Gamma_{j\ k}^{\ i}$ of the Euclidean frame at the initial point coincide with the corresponding values $(\Gamma_{j\ k}^{\ i})_0$ of the Riemannian metric for $u^i = u_0^i$, then not only the coefficients g_{ij} of the line element but also their partial derivatives $\frac{\partial g_{ij}}{\partial u^k}$ are respectively equal in both metrics.

This is not difficult to prove. Since from equations (12.10) and (12.13), it follows that

$$\frac{\partial \mathbf{M}}{\partial u^i} = \mathbf{e}_i, \quad \frac{\partial^2 \mathbf{M}}{\partial u^i \partial u^j} = \Gamma_{i\ j}^{\ k} \mathbf{e}_k, \tag{12.16}$$

we need only to select a parametrization of the Euclidean space in such a way that for $u^i = u_0^i$, equations (12.16) are satisfied.

At an arbitrary point O of the Euclidean space, construct an oblique Cartesian coordinate system $(\mathbf{e}_1, \dots, \mathbf{e}_n)$ such that for $u^i = u_0^i$, the equations

$$\mathbf{e}_i \cdot \mathbf{e}_j = (g_{ij})_0 \tag{12.17}$$

hold. With respect to this coordinate system, define the coordinates x^i of an arbitrary (moving) point of the Euclidean space by means of the equations

$$x^i = u^i - u_0^i + \frac{1}{2}\left(\Gamma_{r\ s}^{\ i}\right)_0 (u^r - u_0^r)(u^s - u_0^s), \quad i = 1, \dots, n. \tag{12.18}$$

The line element of the Euclidean space relative to this system of curvilinear coordinates enjoys the desired properties: the coincidence of the values of γ_{ij} and g_{ij} at the point $u^i = u_0^i$ follows from the construction of the initial frame (in particular, from formulas (12.17)), and the coincidence of the values $\Gamma_{j\ k}^{\ i}$ for the Euclidean space and the Riemannian manifold follows from formulas (12.16) by means of equations (12.18). Thus, at the point $u^i = u_0^i$, the numerical values of the functions γ_{ij}, $\frac{\partial \gamma_{ij}}{\partial u^k}$ and g_{ij}, $\frac{\partial g_{ij}}{\partial u^k}$ are equal.

Chapter 13

Osculating Euclidean Space

68. Absolute differentiation of vectors on a Riemannian manifold. All the geometric notions common to the different osculating Euclidean spaces at a point are obviously intrinsic (invariant) geometric properties of the Riemannian manifold. This is the case for all properties depending on numerical values at the point A of the coefficients g_{ij} and $\Gamma_{i\,j}^{\,k}$.

Let us imagine that in the osculating Euclidean space, the point A and the frame (R_0) attached to this point are fixed. Each point M in the Riemannian manifold is represented by a point $\overline{M}$ whose coordinates, with respect to the frame (R_0), are well defined to within an order of infinitesimals *greater than the second.* The frame attached to the point $\overline{M}$ in the Euclidean space, with respect to its magnitude and orientation, is well defined to within some order of infinitesimals *greater than the first.* Moreover, this frame is equal to the frame attached to the point M in the Riemannian manifold. Every vector of the Riemannian manifold attached to M is represented with the same degree of approximation by an equal vector.

In general, if M and N are any two points in a neighborhood of the point A in the Riemannian manifold and if the points representing M and N in the osculating Euclidean space lie inside a sphere centered at A and of radius r, then the scalar product of two vectors representing vectors attached to M and N are well defined to within infinitesimals of order of radius r inclusively.

In a Riemannian manifold, a vector $\mathbf{X}$ attached to a point A and a vector $\mathbf{X}'$ attached to an infinitesimally close point A' are represented in the osculating Euclidean space by two vectors, whose difference is well defined to within an order of infinitesimals greater than the first. This leads us to extend to an arbitrary Riemannian manifold the notion of the *absolute differential* (or the *covariant differential for the natural frame*) of a vector, or more generally, of a tensor. We shall continue for this absolute differential the same notation D which we used earlier.

From equations (7.17), the absolute differential is

$$DX^i = dX^i + X^k\omega_k^i \tag{13.1}$$

for a contravariant vector (X^i), and

$$DX_i = dX_i - X_k \omega_i^k \tag{13.2}$$

for a covariant vector (X_i). In an orthonormal frame, both definitions coincide, since then

$$X^k = X_k \text{ and } \omega_i^{\cdot k} = \omega_{ik} = \omega^i_{\cdot k} = -\omega_k^{\cdot i}.$$

The minus sign appears because of the change of the order of the indices.

It is important to note that in the Euclidean geometry, the absolute differential is the true differential, while in the geometry of Riemannian manifolds, one cannot be sure that this is the case.

In particular, denoting by $\mathbf{e}_i$ (see No. **4**) the coordinate vectors, we have

$$D\mathbf{e}_i = \omega_i^k \mathbf{e}_k.$$

DEFINITION. Two vectors attached to the two infinitesimally close points A and A' are said to be *equipollent*[1] if the absolute differential of the first vector (when this first vector is transported to the second vector) is equal to zero.

Thus, the conditions for equipollence are

$$dX^i + X^k \omega_k^i = 0, \tag{13.3}$$

or

$$dX_i - X_k \omega_i^k = 0. \tag{13.4}$$

69. Geodesics of a Riemannian manifold. It is not difficult now to define the *acceleration* of a moving point in the Riemannian manifold. If $\mathbf{v}$ is the velocity vector, then the acceleration vector is $\frac{D\mathbf{v}}{dt}$. For example, in order to write the contravariant components γ^i of the acceleration vector with coordinates (u^i) in the natural frame, note that from (12.12), (12.13), and (12.14), it follows that the velocity vector is

$$\mathbf{v} = \frac{D\mathbf{M}}{dt} = \frac{\omega^i}{dt}\mathbf{e}_i = \frac{du^i}{dt}\mathbf{e}_i, \quad v^i = \frac{du^i}{dt}.$$

Applying equations (13.1) to the components v^i and taking into account (12.13), we have

$$\frac{Dv^i}{dt} = \frac{d^2u^i}{dt^2} + \frac{du^i}{dt}\omega_k^i = \frac{d^2u^i}{dt^2} + \frac{du^k}{dt}\Gamma^i_{kh}\frac{du^h}{dt},$$

and hence

$$\gamma^i = \frac{d^2u^i}{dt^2} + \Gamma^i_{kh}\frac{du^k}{dt}\frac{du^h}{dt}. \tag{13.5}$$

A moving point whose acceleration is zero throughout has the velocity which is constantly equipollent to itself. The lines of a Riemannian manifold, whose tangent remains equipollent to itself throughout, are called the *geodesics* (the "straight lines") of the manifold. If a point moves along such a curve and has its velocity equal to 1, then the acceleration is equal to zero. It follows that the equations of geodesics in Riemannian manifolds have the form

---

[1] In modern terminology, the term *parallel* is used. (*Translator's note.*)

$$\frac{d^2u^i}{dt^2} + \Gamma^i_{kh}\frac{du^k}{dt}\frac{du^h}{dt} = 0. \tag{13.6}$$

These equations comprise Cauchy's system for the unknown functions u^i and the independent variable t. Under the hypotheses of Cauchy's theorem, with initial conditions

$$u^i = (u^i)_0, \quad \frac{du^k}{dt} = (v^k)_0 \ \text{ for } t = t_0, \ \ (u^i)_0, (v^k)_0 \ \text{ are constants,} \tag{13.7}$$

such a system has one and only one solution. If we note that the first condition of (13.7) defines an initial point, and the second defines an initial velocity, we obtain the following result.

Theorem 1. *Through a point of a domain of regularity of a Riemannian manifold and in any direction, there passes one and only one geodesic.*

70. Generalization of the Frenet formulas. Curvature and torsion. *The theory of curvature of lines* can be extended without modification from Euclidean space to any Riemannian manifold.

In fact, let M be a point on a curve, $\mathbf{T}$ be a unit tangent vector to the curve at the point M, and ds be the arc element of the curve. The vector $\frac{D\mathbf{T}}{ds}$ is normal to the vector $\mathbf{T}$. This can be seen immediately if one uses the Euclidean space osculating at the point M to the Riemannian manifold.

Suppose that

$$\frac{D\mathbf{T}}{ds} = \frac{1}{\rho}\mathbf{N},$$

where $\mathbf{N}$ is a unit vector (*principal normal*), and $\mathbf{B}$ is the unit vector (the *binormal*), which is orthogonal to $\mathbf{T}$ and $\mathbf{N}$ and forms a right trihedron with them. Suppose also that

$$\frac{D\mathbf{N}}{ds} = \alpha\mathbf{T} + \beta\mathbf{N} + \gamma\mathbf{B},$$

$$\frac{D\mathbf{B}}{ds} = \alpha'\mathbf{T} + \beta'\mathbf{N} + \gamma'\mathbf{B}.$$

The relations

$$\mathbf{T}\cdot\mathbf{N} = 0, \ \ \mathbf{T}\cdot\mathbf{B} = 0, \ \ \mathbf{N}\cdot\mathbf{B} = 0, \ \ \mathbf{N}^2 = 1, \ \ \mathbf{B}^2 = 1$$

on absolute differentiation, yield the following equations:

$$\frac{1}{\rho} + \alpha = 0, \ \ \alpha' = 0, \ \ \gamma + \beta' = 0, \ \ \beta = 0, \ \ \gamma' = 0.$$

Setting now

$$\gamma = -\beta' = \frac{1}{\tau},$$

we obtain the generalized Frenet formulas

$$\begin{cases} \dfrac{D\mathbf{T}}{ds} = \dfrac{1}{\rho}\mathbf{N}, \\ \dfrac{D\mathbf{N}}{ds} = -\dfrac{1}{\rho}\mathbf{T} + \dfrac{1}{\tau}\mathbf{B}, \\ \dfrac{D\mathbf{B}}{ds} = -\dfrac{1}{\tau}\mathbf{N}. \end{cases} \tag{13.8}$$

The quantities $\frac{1}{\rho}$ and $\frac{1}{\tau}$ in these formulas are respectively the *curvature* and *torsion* of the curve. The "straight lines" (geodesics) of the Riemannian manifold are curves of zero curvature. As for the curves of zero torsion, they are characterized by the following properties:

1°) The osculating plane element at a point M of the curve is parallel to the osculating plane element at an infinitesimally close point M'.

2°) The vectors

$$\mathbf{T} + D\mathbf{T}, \quad \mathbf{N} + D\mathbf{N},$$

that are the unit vectors taken along the tangent and the principal normal to the curve at the point M' become

$$\mathbf{T} + \frac{ds}{\rho}\mathbf{N}, \quad \mathbf{N} - \frac{ds}{\rho}\mathbf{T} + \frac{ds}{\tau}\mathbf{B}.$$

These new vectors lie in the osculating plane element at the point M if and only if *the torsion* $\frac{1}{\tau}$ vanishes.

If we represent the Riemannian manifold in the osculating Euclidean space at the point M, then the image of the given curve (C) is a certain curve (Γ) *having the same curvature at the point M as (C)*. Moreover, the vectors $\mathbf{T}, \mathbf{N}$, and $\mathbf{B}$ on the curve (Γ) are the images of the similar vectors on the curve (C). The following explanation makes this even more clear. *Whether we adapt the given metric or an osculating Euclidean metric at the point M, the curve (C) has the same tangent, principal vector, binormal, and the same curvature as (Γ). But (C) does not have the same torsion with the two metrics.* In particular, for an observer who would adapt an osculating Euclidean metric at M, every straight line (every geodesic) in the Riemannian manifold represents a point of inflection at M.

71. The theory of curvature of surfaces in a Riemannian manifold. The classical theory of curvature of surfaces can be extended to Riemannian manifolds quite easily.[2] The different curves on a surface (S) passing through a given point M of (S), have the same principal normal and even the same curvature in both metrics, the metric of the Riemannian manifold or the osculating Euclidean metric, adapted to M. It follows that the laws which govern the variation of the curvature of these curves, when their tangents at the point M are varied, are the same as for the Euclidean space.

All curves tangent to one another have the same *normal curvature.* This normal curvature is equal to $\frac{\cos V}{\rho}$, where V is the angle of the principal normal to the curve with the surface normal, and ρ is the radius of curvature of the curve. This result is *Meusnier's theorem.*

There exist two orthogonal directions tangent to the surface corresponding to the maximum and minimum normal curvature. These directions are called the *principal directions.* The normal curvatures corresponding to these directions are the *principal curvatures.*

The *curvature lines* are the lines which, at each of their points, are tangent to one of principal directions at that point. If θ is the angle formed by a curve with the curvature line of the first family, then we have for this curve

$$\frac{\cos V}{\rho} = \frac{\cos^2\theta}{R_1} + \frac{\sin^2\theta}{R_2}, \tag{13.9}$$

where $\dfrac{1}{R_1}$ and $\dfrac{1}{R_2}$ are the two principal curvatures.

The *asymptotic curves* are those whose normal curvature is zero. The osculating plane element of such curves is tangent to the surface. The straight line (the geodesic) of the Riemannian manifold tangent to an asymptotic line at a point M has a second-order tangency at this point with the surface.

The curvature lines can also be characterized by the following condition: for any given point M on the curve, the tangent to the curvature line at M, the surface normal at M, and the surface normal at an infinitesimally close point M' of this line, once transported by parallelism from M' to M, lie in the same plane element.

Denote by ν the unit vector of the surface normal, and by $\mathbf{T}_1$ and $\mathbf{T}_2$ the unit vectors of the tangents to the curvature lines. Then, for a displacement in the direction of the vector $\mathbf{T}_1$ with length ds_1, we have

$$D_1\nu = -\frac{ds_1}{R_1}\mathbf{T}_1.$$

Then, for a displacement in the direction of the vector $\mathbf{T}_2$ with length ds_2, we have

$$D_2\nu = -\frac{ds_2}{R_2}\mathbf{T}_2.$$

These formulas represent a generalization to the Riemannian manifolds of the classical *Olinde Rodriques equations.*

---

[2] The theory of curvature of surfaces in the Euclidean space is the subject of Chapter 23.

For a displacement with length ds in the direction making an angle θ with the principal direction $\mathbf{I}_1$, in general we have

$$\frac{D\nu}{ds} = -\frac{\cos\theta}{R_1}\mathbf{T}_1 - \frac{\sin\theta}{R_2}\mathbf{T}_2. \tag{13.10}$$

Finally, the total curvature $\frac{1}{R_1R_2}$ of the surface at a point M could be defined by the method applied by Gauss to the Euclidean space. Take a surface element $d\sigma$ enclosing the point M and the sphere of center M and of radius 1 in the Euclidean space tangent at M to the Riemannian manifold. Transport by parallelism to the point M the surface normals at the different points of the element $d\sigma$, and consider a small region of the sphere defined by the intersection with the sphere of the normals so transported. The limit of the ratio $\frac{d\omega}{d\sigma}$ of the area of this portion of the sphere to the given area $d\sigma$ is equal to the total curvature $\frac{1}{R_1R_2}$. We could the consider $d\omega$ as the solid angle of the cone at the vertex M obtained by transporting by parallelism at M the normals emanating from the different points of the element $d\sigma$.

72. Geodesic torsion. The Enneper theorem. The notion of the *geodesic torsion* of a curve on a surface can be extended to the most general Riemannian manifolds.

In fact, denote by $\mathbf{T}, \mathbf{N}$, and $\mathbf{B}$ the unit vectors along the tangent, principal normal, and binormal to the curve respectively, and keep the same notations $\mathbf{T}_1, \mathbf{T}_2$, and ν for the unit vectors along the tangents to the principal directions and the surface normal. Finally, denote by θ the angle formed by the tangent to the curve with the tangent to the first principal direction, and by V the angle of the principal normal to the curve and the surface normal. The direction cosines of the vectors $\mathbf{T}, \mathbf{N}$, and $\mathbf{B}$ with respect to the vectors $\mathbf{T}_1, \mathbf{T}_2$, and $\boldsymbol{\nu}$ are given in Table 13.1:

	$\mathbf{T}_1$	$\mathbf{T}_2$	$\boldsymbol{\nu}$
T	$\cos\theta$	$\sin\theta$	0
N	$-\sin\theta\sin V$	$\cos\theta\sin V$	$\cos\theta$
B	$\sin\theta\cos V$	$-\cos\theta\cos V$	$\sin\theta$

Table 13.1

Let us start with the generalized Frenet formulas

$$\begin{cases} \dfrac{D\mathbf{T}}{ds} = \dfrac{1}{\rho}\mathbf{N}, \\ \dfrac{D\mathbf{N}}{ds} = -\dfrac{1}{\rho}\mathbf{T} + \dfrac{1}{\tau}\mathbf{B}, \\ \dfrac{D\mathbf{B}}{ds} = -\dfrac{1}{\tau}\mathbf{N} \end{cases} \tag{13.11}$$

and the equation

$$\frac{D\nu}{ds} = -\frac{\cos\theta}{R_1}\mathbf{T}_1 - \frac{\sin\theta}{R_2}\mathbf{T}_2.$$

Differentiating the relations

$$\mathbf{T}\cdot\nu = 0, \quad \mathbf{N}\cdot\nu = \cos V, \quad \mathbf{B}\cdot\nu = \sin V,$$

we obtain two distinct equations:

$$\frac{\cos V}{\rho} = \frac{\cos^2\theta}{R_1} + \frac{\sin^2\theta}{R_2}, \tag{13.12}$$

$$\frac{dV}{ds} + \frac{1}{\tau} = \left(\frac{1}{R_1} - \frac{1}{R_2}\right)\sin\theta\cos\theta. \tag{13.13}$$

The left-hand side of equation (13.13) is a quantity called the *geodesic torsion* of the curve. The form of the right-hand side shows that all curves with the same tangent have the same geodesic torsion. The geodesic torsion vanishes for the curvature lines.

If we apply equation (13.13) to an asymptotic line which is not a straight line ($V = \frac{\pi}{2}$), then we obtain

$$\frac{1}{\tau} = \left(\frac{1}{R_1} - \frac{1}{R_2}\right)\sin\theta\cos\theta.$$

But for an asymptotic line, we have

$$\frac{\cos^2\theta}{R_1} + \frac{\sin^2\theta}{R_2} = 0,$$

and this implies that[3]

$$\frac{1}{\tau} = \pm\sqrt{-\frac{1}{R_1R_2}}.$$

---

[3] In fact, we have $\frac{1}{\tau} = \frac{\cos\theta}{R_1\sin\theta}$ or $\frac{1}{\tau^2} = -\frac{1}{R_1R_2}$. (*Translator's note.*)

This is the *Beltrami-Enneper theorem* for an arbitrary Riemannian manifold.

The asymptotic lines emanating from a point M of a surface have at that point torsions equal in absolute values but with opposite signs. The common absolute value of these torsions is equal to the square root of the total curvature of the surface taken with the sign changed.

In particular, the torsion of a doubly-asymptotic line is constantly zero.

It is known that, in Euclidean space, if two families of asymptotic lines coincide, then the asymptotic lines are straight lines. This theorem is no longer true in an arbitrary Riemannian manifold.[4] Nevertheless, by means of the Enneper theorem, we can affirm that they are curves with zero torsion.

73. Conjugate directions. The theory of *conjugate tangents* also generalizes to an arbitrary Riemannian manifold. If M and M' are two infinitesimally close points on a curve (C) traced on a surface (S), then the plane element tangent to the surface (S) at the point M', being transported by parallelism at the point M, has a certain direction, conjugate to the direction of (C) at M, in common with the plane element tangent to (S) at M. Two conjugate directions are harmonically conjugate with respect to the asymptotic directions. Finally, when we pass from M to M', the absolute differential of the unit vector of the surface normal is perpendicular to the conjugate direction of the curve. All these properties become trivial if we represent the Riemannian manifold in the osculating Euclidean space at the point M.

74. The Dupin theorem on a triply orthogonal system. We conclude with the *famous Dupin theorem.* As is known, a triply orthogonal system is a system formed by three one-parameter families of surfaces that intersect at right angles. The Dupin theorem states that the intersecting curves of each pair of surfaces from two different families is a curvature line for each of these surfaces.

The analytic proof that we are going to present can be applied just as well to Riemannian manifolds as to Euclidean spaces.

Since the cosines of the angles between the two intersecting coordinate curves is zero, the line element of our manifold is

$$ds^2 = g_{22}(du^1)^2 + g_{11}(du^2)^2 + g_{33}(du^3)^2.$$

For example, the condition, expressing the fact that the coordinate line (C_1) (u^1 a variable) is a curvature line for the surface (S_1) (u^2 a constant), is that the vector

$$\mathbf{e}_3 + D_1\mathbf{e}_3 du^1,$$

normal to (S_1) at the point M' infinitesimally close to the point M on the line (C_1), must belong to the same plane element as the vectors $\mathbf{e}_3$ and $\mathbf{e}_1$. In other words, the coefficient of $\mathbf{e}_2$ in the expression of $D_1\mathbf{e}_3$ is zero. But we have

---

[4] É. Cartan, *Sur les courbes de torsion nulle et les surfaces développables dans les espaces de Riemann*, Comptes Rendus Acad. Sc. **184** (1927), 138–141. (JFM **53**, p. 696.)

$$D\mathbf{e}_3 = \omega_3^1\,\mathbf{e}_1 + \omega_3^2\,\mathbf{e}_2 + \omega_3^3\,\mathbf{e}_3,$$

$$D_1\mathbf{e}_3 = \Gamma_3{}^1{}_1\mathbf{e}_1 + \Gamma_3{}^2{}_1\mathbf{e}_2 + \Gamma_3{}^3{}_1\mathbf{e}_3.$$

Thus, we need to prove that $\Gamma_3{}^2{}_1 = 0$. But taking equation (12.14) for $i = 1$, $j = 2$, $h = 3$ and applying equations $g_{23} = g_{31} = g_{12} = 0$, we come to the equations

$$\Gamma_1{}^2{}_3\, g_{22} + \Gamma_2{}^1{}_3\, g_{11} = 0,$$

$$\Gamma_2{}^3{}_1\, g_{33} + \Gamma_3{}^2{}_1\, g_{22} = 0,$$

$$\Gamma_3{}^1{}_2\, g_{11} + \Gamma_1{}^3{}_2\, g_{33} = 0,$$

where the last two equations are obtained from the first by cyclic permutation of the indices 1, 2, 3. By (12.13), the coefficients $\Gamma_i{}^k{}_j$ are symmetric with respect to the lower indices. Thus, adding the first two equations and subtracting the third, we obtain

$$2\Gamma_3{}^2{}_1\, g_{22} = 0, \quad g_{22} \neq 0,$$

and as a result, we have

$$\Gamma_3{}^2{}_1 = 0.$$

Chapter 14

Euclidean Space of Conjugacy along a Line

75. Development of a Riemannian manifold in Euclidean space along a curve. The development of a Riemannian manifold in Euclidean space along a curve opens up new possibilities.

Suppose that coordinates of a varying point of a curve are expressed in terms of a parameter t which takes the value $t = 0$ at an initial point A_0. In a Euclidean space, take an origin O to which we attach a Cartesian frame R_0 determined in size and shape by the numerical values of the coefficients g_{ij} at the point A_0. With each point $M(t)$, we associate a point M' of the Euclidean space and a Cartesian frame $(\mathbf{e}'_i)$ attached to M'. We shall start with equations (I) of No. **26** and suppose that the frame $(\mathbf{e}'_i)$ is natural. Then we have

$$\begin{cases} d\mathbf{M}' = du^i \mathbf{e}'_i, \\ d\mathbf{e}'_i = \omega_i^j \mathbf{e}'_j \end{cases} \tag{14.1}$$

with the independent variable t and the initial conditions: for $t = 0$, the point M' coincides with the point O, and the vector $(\mathbf{e}'_i)$ coincides with the vector $(\mathbf{e}_i)$ of the frame (R_0). As in No. **28**, we can prove that in the frame $(R) = (\mathbf{e}'_i)$ attached to the point $M'(t)$, the scalar products $\mathbf{e}'_i \cdot \mathbf{e}'_j$ of its vectors are equal to the coefficients g_{ij}. Furthermore, if M and M_1 are arbitrary infinitesimally close points on a given curve, and M' and M'_1 are their images in the Euclidean space, then two equipollent vectors at the points M and M_1 have for their images two equipollent (simply parallel) vectors with at M' and M'_1.

Since a Cartesian frame (R) is attached to each point M', in fact, we obtain a development in Euclidean space not only of the given line but also of an entire infinitesimally small neighborhood of this line in the Riemannian manifold. In order to get the absolute geometric variation of a vector, whose initial point describes the arc of the given line in the Riemannian manifold, *it suffices to* *construct the ordinary geometric difference between the two vectors obtained in the preceding development.*

Thus, we have obtained a rigorous and precise realization of this absolute geometric variation. Now we also know precisely what is meant by "transport by the principle of equipollence[1] of a vector along a given path."

76. The constructed representation and the osculating Euclidean space. We prove now that the development obtained at each point of the curve enjoys the properties of an osculating Euclidean space. This means that we prove that along the curve, the constructed Euclidean line element with the variables u^i has the same numerical values of the coefficients g_{ij} and their first-order partial derivatives as those of the given line element.

Consider the operation of development in the Euclidean space in more detail. For simplicity, we take $n = 3$, and without loss of generality, assume that the line is defined by the equations $u^1 = 0$, $u^2 = 0$.

The development in the Euclidean space gives us the point M' and the vectors $\mathbf{e}'_1, \mathbf{e}'_2, \mathbf{e}'_3$ as functions of u^3. By means of equations (14.1), we obtain

$$\left\{\begin{aligned} &\frac{d\mathbf{M}'}{du^3} = \mathbf{e}'_3, \\ &\frac{d\mathbf{e}'_i}{du^3} = \Gamma_{i}{}^{k}{}_{3}\mathbf{e}'_k. \end{aligned}\right. \tag{14.2}$$

Next we find, in terms of functions u^1, u^2, and u^3, a point P of the Euclidean space satisfying the following initial conditions: for $u^1 = 0$, $u^2 = 0$,

$$\left\{\begin{gathered} \mathbf{P} = \mathbf{M}', \\ \frac{\partial \mathbf{P}}{\partial u^1} = \mathbf{e}'_1, \quad \frac{\partial \mathbf{P}}{\partial u^2} = \mathbf{e}'_2, \\ \frac{\partial^2 \mathbf{P}}{(\partial u^1)^2} = (\Gamma_{1}{}^{k}{}_{1})^* \mathbf{e}'_k, \quad \frac{\partial^2 \mathbf{P}}{\partial u^1 \partial u^2} = (\Gamma_{1}{}^{k}{}_{2})^* \mathbf{e}'_k, \quad \frac{\partial^2 \mathbf{P}}{(\partial u^2)^2} = (\Gamma_{2}{}^{k}{}_{2})^* \mathbf{e}'_k. \end{gathered}\right. \tag{14.3}$$

where $(\Gamma_{i}{}^{k}{}_{j})^*$ are the values of these coefficients for $u^1 = 0$, $u^2 = 0$.

Of course, these conditions are compatible with each other. It suffices, for example, to take

$$\begin{aligned} \mathbf{P} = \mathbf{M} + u^1\mathbf{e}'_1 + u^2\mathbf{e}'_2 + \frac{1}{2}(u^1)^2(\Gamma_{1}{}^{k}{}_{1})^*\mathbf{e}'_k \\ + u^1u^2(\Gamma_{1}{}^{k}{}_{2})^*\mathbf{e}'_k + \frac{1}{2}(u^2)^2(\Gamma_{2}{}^{k}{}_{2})^*\mathbf{e}'_k. \end{aligned}$$

In this formula, Euclidean space is related to a system of curvilinear coordinates u^1, u^2, u^3. For $u^1 = 0, u^2 = 0$, the natural frame attached to the point P (which reduces here to the point M') is determined by the vectors $\frac{\partial \mathbf{P}}{\partial u^i}$, which reduce here to the vectors $\mathbf{e}'_1, \mathbf{e}'_2, \mathbf{e}'_3$. The coefficients of the line element ds^2 in the Euclidean space are the coefficients of the given line element of the Riemannian manifold. As for the coefficients $\Gamma_{i\ j}^{\ k}$ of the Euclidean space, they are obtained if one compares the coefficients of $\mathbf{e}'_k$ in the expression $\frac{\partial^2 \mathbf{P}}{\partial u^i \partial u^j}$. If the indices i and j are both distinct from 3, then by applying (14.3), we find the coefficients $\Gamma_{i\ j}^{\ k}$ in the Riemannian manifold. If $i \neq 3$ and $j = 3$, then on account of (14.2) and for $u^1 = 0$, $u^2 = 0$, we find that

---

[1] This is "parallel transfer" or "parallel transport" in modern terminology. (*Translator's note.*)

$$\left(\frac{\partial^2 \mathbf{P}}{\partial u^i \partial u^3}\right)_0 = \frac{d}{du^3}\left(\frac{\partial \mathbf{P}}{\partial u^i}\right)_0 = \frac{d\mathbf{e}'_i}{du^3} = (\Gamma_{i\ 3}^{\ k})^* \mathbf{e}'_k,$$

and the conclusion is the same. Finally, if $i = j = 3$, then

$$\left(\frac{\partial^2 \mathbf{P}}{(\partial u^3)^2}\right)_0 = \frac{d\mathbf{e}'_3}{du^3} = (\Gamma_{3\ 3}^{\ k})^* \mathbf{e}'_k,$$

and again the conclusion is the same.

We see that *the determination of a Euclidean space of conjugacy along a given curve does not require integration, once the development of the curve on the Euclidean space is carried out.*

This result has numerous important consequences. First of all, *an observer, who moves only along the given line and is content to restrict his measurements to an immediate neighborhood of this line, would not be able to see that he is outside a Euclidean space as long as he neglects infinitesimals of an order greater than the first.*

Another important consequence is as follows: if, in a Riemannian manifold, one considers an arc of a curve infinitesimally close to the curve (C), then *the length of this arc, measured by the metric of the Riemannian manifold or by the Euclidean metric of conjugacy along the curve (C), is the same up to the second-order infinitesimals.* [2]

In fact, at a point infinitesimally close to the curve (C), the coefficients of the given line element and the line element of the Euclidean space of conjugacy are equal up to second-order infinitesimals. Thus, *the representation of the Riemannian manifold upon the Euclidean space of conjugacy preserves the distances measured in the neighborhood of the given line up to the same order.*

77. Geodesics. Parallel surfaces. When one develops a curve on a Euclidean space, at each of its points, the developed curve has the same curvature and the same torsion as the given curve, since in development, the absolute differential of a vector, whose initial point describes the curve, becomes the ordinary geometric variation of this vector. The generalized Frenet formulas become, in the Euclidean space of conjugacy, the *usual* Frenet formulas:

---

[2] It is necessary to assume than the two arcs of the curves in question correspond, point by point, in a way that at two corresponding points, the directions of the tangent elements are infinitesimally close.

$$\begin{cases} \dfrac{d\mathbf{T}}{ds} = \dfrac{1}{\rho}\mathbf{N}, \\ \dfrac{d\mathbf{N}}{ds} = -\dfrac{1}{\rho}\mathbf{T} + \dfrac{1}{\tau}\mathbf{B}, \\ \dfrac{d\mathbf{B}}{ds} = -\dfrac{1}{\tau}\mathbf{N}. \end{cases}$$

Thus, a curve with zero torsion is so developed along a plane curve, and a curve with zero curvature is developed along a straight line.

The straight lines (the geodesics) of a Riemannian manifold are therefore the curves whose development is along a straight line. This immediately implies that the straight lines (the geodesics) in our definition are equivalent to the straight lines in Riemann's definition.

In fact, if a curve (C) is developed along a straight line, and in a Riemannian manifold we take a curve (C') infinitesimally close to (C), which emanates from a given point A of (C), and ends at another given point B of (C), then the image, *a curve in the Euclidean space of conjugacy*, has the same length as (C), up to second-order infinitesimals. But in this Euclidean space, the line, which is the image of the curve (C'), results from the variation of a straight line segment. Thus, its length is *the same* as the length of the line segment up to second-order infinitesimals. Consequently, in the Riemannian manifold, the first variation of the length of a segment of a straight line (a geodesic) is identically zero, and the "straight line" (the geodesic) realizes the extremum of the distance conforming to the classical definition of Riemann.

This implies another *consequence*: if we consider a geodesic arc AB and an infinitesimally close geodesic arc $A'B'$, then as *in the Euclidean space*, up to second-order infinitesimals, we have

$$\text{arc } A'B' - \text{arc } AB = -AA' \cos(\widehat{AB, AA'}) - BB' \cos(\widehat{BA, BB'}).$$

In particular, taking a constant length R starting from the point A along the different geodesics emanating from A, we obtain a certain surface similar to the sphere as a region between the extremities. *The tangent plane element to this surface at a point M is normal to the geodesic emanating from A and ending at the point M.* The same applies if we consider a family of geodesics generating the surface from A only. Namely, if we take a constant length on each of these geodesics, then the line element tangent at any point M in the region between extremities is orthogonal to the geodesic emanating from A and ending at M.

One other consequence is the generalization of the property of *parallel surfaces*. If we construct normal geodesics at different points of a surface and take a constant length on each of them, then the region of the points so obtained is a surface which, at each of its points, is normal to the corresponding geodesic. It follows that if a two-parameter family of geodesics is normal to a surface, then it is normal to an infinity of surfaces.

78. Geodesics on a surface. In general, what we did above for a line is impossible to do for a surface. *In general, there is no Euclidean space of conjugacy along a surface.* The reason for this is very simple: in general, it is impossible to develop a surface in Euclidean space. Nevertheless, *if a development in Euclidean space is possible, then there exists a Euclidean space of conjugacy along a surface.*

Note the final application of the Euclidean space of conjugacy. In a three-dimensional Euclidean space, take a surface (S) and *a geodesic* (C) *of this surface*, i.e., a line realizing the minimum of distance *on a surface.* In the Euclidean space of conjugacy along the curve (C), the line (C) has a stationary length with respect to all lines on (S) having their ends at two given points of (C). Thus, by a classical property of geodesics on a surface of the Euclidean space, the osculating plane at any point of the line (C) is normal to the surface. *This property*, which is valid for the Euclidean space of conjugacy, *is also valid for a Riemannian manifold.*

Chapter 15

Space with a Euclidean Connection

79. Determination of forms ω_i^j for given forms ω^i. In No. **66** we posed the problem of finding a connection of a Riemannian manifold and outlined certain ways to solve this problem. First, we discovered that this problem is equivalent to the problem of absolute differentiation of vectors and depends on the choice of coefficients $\Gamma_{i\ k}^{\ j}$ (sometimes called the object of connection[1] or the forms ω_i^j).

We made broad use of the notion of the metric osculating at a point and obtained a series of geometric results.

Now we want to investigate to what degree we need the postulate on extending a connection of an osculating metric into a Riemannian manifold.

In order not to complicate the situation by the choice of frame, we assume that an orthonormal frame is assigned to every point of the Riemannian manifold.

We saw (No. **64**) that it is sufficient to reduce a positive definite quadratic form to a sum of squares (this is always possible),

$$ds^2 = (\omega^1)^2 + (\omega^2)^2 + \ldots + (\omega^n)^2, \tag{15.1}$$

in order that the forms ω^i define an orthonormal frame.

Will this determine the forms ω_i^j ?

We saw that in the Euclidean space, the forms ω^i and ω_i^j satisfy structure equations (II) of No. **26**,

$$d\omega^i = \omega^k \wedge \omega_k^i, \tag{II$_1$}$$

$$d\omega_i^j = \omega_i^k \wedge \omega_k^j, \tag{II$_2$}$$

and of course, the orthonormality condition

$$\omega_i^j = -\omega_j^i. \tag{15.2}$$

---

[1] They are now called the connection coefficients. (*Translator's note.*)

Conditions (15.2) followed from our choice an orthonormal frame. So, we need to investigate two equations (II_1) and (II_2). If both of them are satisfied, then the space is Euclidean. Equation (II_2) does not contain the forms ω^i at all, but these forms determine the line element (15.1). Thus, it is natural to search for the forms ω_i^j satisfying the system of equations (II_1) and (15.2).

Theorem 1. *If the forms ω^i are given, then it is possible to find the $\frac{n(n-1)}{2}$ forms ω_i^j satisfying the system of equations* (II_1) *and* (15.2), *and such a solution of this system is unique.*

Proof. We assume that only one frame is associated with each point of the space. Hence the forms ω_i^j are linear combinations of the forms ω^i:

$$\omega_i^j = \gamma_i{}^j{}_k \omega^k. \tag{15.3}$$

We need to find the coefficients $\gamma_i{}^j{}_k$ in such a way that they satisfy the system of equations (II_1) and (15.2).

Exterior differentiation of the given forms ω^i gives us the exterior quadratic form with respect to the basis forms ω^k in the form [2]

$$d\omega^i = c^i_{[jk]}\omega^j \wedge \omega^k, \quad c^i_{[jk]} = c^i_{jk} - c^i_{kj}. \tag{15.4}$$

Then equations (II_1) take the form

$$c^i_{[jk]}\omega^j \wedge \omega^k = \omega^k \wedge \omega^i_k. \tag{15.5}$$

Substituting expressions (15.3) into equations (15.5) and (15.2) and comparing the coefficients in independent products $\omega^j \wedge \omega^k$, we obtain

$$c^i_{[jk]} = \gamma^i_{jk} - \gamma^i_{kj}, \tag{15.6}$$

$$0 = \gamma^i_{jk} + \gamma^j_{ik}. \tag{15.7}$$

Equations (15.6) and (15.7) determine γ^i_{jk} uniquely.

In fact, twice making the cyclic permutation of the indices i, j, k in equations (15.6) and applying relations (15.7), we find that

$$\left\{\begin{aligned} c^i_{[jk]} &= \gamma^i_{jk} + \gamma^k_{ij}, \\ c^j_{[ki]} &= \gamma^j_{ki} + \gamma^i_{jk}, \\ c^k_{[ij]} &= \gamma^k_{ij} + \gamma^j_{ki}. \end{aligned}\right.$$

---

[2] Here and in what follows, it is assumed that for the alternated coefficients $c^i_{[jk]}$ the summation is carried over all combinations (j,k) of indices j and k:

$$c^i_{[jk]}\omega^j \wedge \omega^k = \sum_{(j,k)} c^i_{jk}\omega^j \wedge \omega^k.$$

Adding the first two equations and subtracting the third, we obtain

$$\gamma^i_{jk} = \frac{c^i_{[jk]} + c^j_{[ki]} - c^k_{[ij]}}{2}. \tag{15.8}$$

80. Condition of invariance of line element. Suppose now that the quadratic form ds^2 is decomposed into a sum of squares in the most general way, i.e., with $\frac{n(n-1)}{2}$ parameters

$$v^1, v^2, \ldots, v^{\frac{n(n-1)}{2}}$$

(this is the same as the number of independent forms ω^j_i satisfying equations (15.2)). The difficulty of the problem depends on the fact that although the forms ω^i are linear combinations of $du^1, \ldots, du^n$, the coefficients of these linear combinations can depend on u^i and v^α. Thus, after exterior differentiation the differentials dv^α can occur. By hypothesis, the line element

$$ds^2 = (\omega^1)^2 + (\omega^2)^2 + \ldots + (\omega^n)^2$$

does not depend on v^α. We now discuss how to express this condition.

It is always possible to choose new forms $\widetilde{\omega}^i_k$, which can also depend also on v^α and dv^α, in such a way that

$$d\omega^i = \omega^k \wedge \widetilde{\omega}^i_k, \tag{15.9}$$

or in bilinear form,

$$d\,\omega^i(\delta) - \delta\,\omega^i(d) = \omega^k(d)\,\widetilde{\omega}^i_k(\delta) - \omega^k(\delta)\,\widetilde{\omega}^i_k(d). \tag{15.10}$$

Suppose that the symbol d of differentiation corresponds to differentiation with respect to the variables u^i, and the symbol δ corresponds to differentiation with respect to the variables v^α. Then, by hypothesis, we have

$$\omega^i(\delta) = 0.$$

Denote also

$$\widetilde{\omega}^i_k(\delta) = e^i_k, \quad \omega^i(d) = \omega^i.$$

Then equations (15.10) take the form

$$\delta\,\omega^i = -e^i_k\,\omega^k.$$

Differentiating ds^2 with respect to the parameter v^α, we find that

$$\delta\,(ds^2) = 2\sum_i \omega^i\,\delta\omega^i = -2e_{ki}\,\omega^i\,\omega^k.$$

By hypothesis, $\delta(ds^2) = 0$. Hence,

$$e_{ki}\,\omega^i\,\omega^k = 0.$$

As a result, for any choice of the forms ω^k, all coefficients of $(\omega^i)^2$ and $\omega^i\omega^j (i \neq j)$ vanish,

$$e_{ii} = 0 \;\; (i \text{ not summed}), \;\; e_{ij} + e_{ji} = 0.$$

This proves that for fixed u^i, we have

$$\widetilde{\omega}_i^j(\delta) + \widetilde{\omega}_j^i(\delta) = 0.$$

Therefore, for any change of secondary parameters v^α, this sum depends only on the differentials $du^1, du^2, \dots, du^n$, i.e., it depends on the forms ω^i. Thus,

$$\widetilde{\omega}_i^j(\delta) + \widetilde{\omega}_j^i(\delta) = a_{ik}^j \omega^k, \;\; a_{ik}^j = a_{jk}^i. \tag{15.11}$$

Now we will show how to write the form ω_i^j as a sum of the form $\widetilde{\omega}_i^j$, which can depend on dv^α, and a linear combination of the forms ω^i:

$$\omega_i^j = \widetilde{\omega}_i^j + \lambda_{ik}^j \omega^k, \tag{15.12}$$

where the coefficients λ_{ik}^j are unknown functions.

Equations (15.2) give now

$$\widetilde{\omega}_i^j + \widetilde{\omega}_j^i + (\lambda_{ik}^j + \lambda_{jk}^i)\omega^k = 0,$$

or by means of (15.11),

$$(a_{jk}^i + \lambda_{ik}^j + \lambda_{jk}^i)\, \omega^k = 0, \tag{15.13}$$

i.e.,

$$a_{jk}^i + \lambda_{ik}^j + \lambda_{jk}^i = 0. \tag{15.14}$$

The difference between equations (II_1) and (15.9) is

$$\omega^k \wedge (\omega_k^i - \widetilde{\omega}_k^i) = 0,$$

or by means of (15.12),

$$\lambda_{kh}^i \, \omega^k \wedge \omega^h = 0,$$

i.e.,

$$\sum_{(k,h)} (\lambda_{kh}^i - \lambda_{hk}^i)\, \omega^k \wedge \omega^h = 0.$$

Since the forms $\omega^k \wedge \omega^h$ are linearly independent, we find that

$$\lambda_{kh}^i - \lambda_{hk}^i = 0. \tag{15.15}$$

Making in (15.14) the cyclic permutation of the indices i, j, k, we obtain

$$\begin{cases} a_{ik}^j + \lambda_{ik}^j + \lambda_{jk}^i = 0, \\ a_{ji}^k + \lambda_{ji}^k + \lambda_{ki}^j = 0, \\ a_{kj}^i + \lambda_{kj}^i + \lambda_{ij}^k = 0. \end{cases} \tag{15.16}$$

Subtracting the sum of the first two equations from the third and applying (15.15), we get

$$\lambda^j_{ik} = \frac{a^i_{kj} - a^j_{ik} - a^k_{ji}}{2}. \tag{15.17}$$

Here, from (15.11), the coefficients a^j_{ik} are symmetric with respect to the indices i and j—this also can be seen from equations (15.16). The solution (15.17) satisfies the system of equations (15.14) and (15.15). Thus, it is always possible to find a solution of equations (15.1) and (15.2). Theorem 1 is proved. ☐

81. Axioms of equipollence of vectors. Can the same absolute differentiation $D\mathbf{X} = (dX^i + X^k\omega^i_k)\mathbf{e}_i$ correspond to two different decompositions of ds^2 into sums of squares? We saw that to any decomposition of ds^2 into sums of squares, there is a certain corresponding connection given by its components ω^j_i. These components, and only these components, satisfy the first group of structure equations (II_1). Since a connection defined by the osculating Euclidean space is also defined up to transformations of coordinate lines, and the components of this connection satisfy equations (II_1), the two connections coincide.

We proved above that this connection can be obtained as a solution of the system of equations (II_1) and (15.2). In order to generalize the notion of equipollence of vectors, we must use another approach.

Suppose that two infinitesimally close points M and N are given. Establish a correspondence of *equipollence* between vectors at M and N (Levi–Civita's parallelism) by the following five requirements:

1°. *If a vector* $\mathbf{X}'$ *is equipollent to a vector* $\mathbf{X}$, *then a vector* $m\mathbf{X}$ *is equipollent to a vector* $m\mathbf{X}'$, *where* m *is an arbitrary factor.*

These and the remaining requirements can be written as the formulas:

1°. If $\mathbf{X} \approx \mathbf{X}'$, then $m\mathbf{X} \approx m\mathbf{X}'$.

2°. If $\mathbf{X} \approx \mathbf{X}', \mathbf{Y} \approx \mathbf{Y}'$, then $\mathbf{X} + \mathbf{Y} \approx \mathbf{X}' + \mathbf{Y}'$.

3°. If $\mathbf{X} \approx \mathbf{X}'$, then $\mathbf{X}^2 \approx (\mathbf{X}')^2$, i.e., *equipollent vectors have equal lengths.*

4°. *If* $\mathbf{X} \approx \mathbf{X}'$, *then the difference of the corresponding components of these vectors is infinitesimally small.*

5°. This requirement will be given later.

Conditions 1° and 2° show that the vectors $\mathbf{X}$ and $\mathbf{X}'$ are linearly related:

$$X^{i'} = \alpha^i_k X^k.$$

From condition 4°, it follows that the last equation can be written in the form

$$X^{i'} = X^i + \omega^i_k X^k, \tag{15.18}$$

where ω^i_k are infinitesimally small.

Now we formulate the fifth condition:

5°. *The components ω^i_k are linear with respect to the differentials of independent variables.*

Condition 3° shows the equality of sums of squares of components of the vectors $\mathbf{X}$ and $\mathbf{X}'$:

$$\sum_i (X^i)^2 = \sum_i (X^{i'})^2.$$

Substituting (15.18) into the last equation and using the distributive law, we get

$$\begin{aligned}\sum_i (X^i)^2 &= \sum_i (X^i + \omega^i_k X^k)^2 \\ &= \sum_i (X^i)^2 + 2\sum_{i,k} X^i X^k + \sum_i (\omega^i_k X^k)^2.\end{aligned}$$

Cancelling out the first terms $\sum_i (X^i)^2$ and neglecting the last term (as infinitesimally small of second order), we get

$$\sum_{i,k} \omega^i_k X^i X^k = 0.$$

Summing in the last equation over the combinations (i,k) of i and k, we obtain

$$\sum_i \omega^i_i (X^i)^2 + \sum_{(i,k)} (\omega^i_k + \omega^k_i) X^i X^k = 0.$$

Since the vector X^i is arbitrary, we have

$$\omega^i_i = 0 \ \ (i \text{ not summed}), \ \ \omega^i_k + \omega^k_i = 0. \tag{15.19}$$

It follows that if

$$\mathbf{X}' = \mathbf{X} + d\mathbf{X},$$

then

$$dX^i = \omega^i_k X^k,$$

or

$$X^{i'} = X^i + \omega^i_k X^k. \tag{15.20}$$

This formula has the same form as earlier, but now all ω^j_i are arbitrary skew-symmetric forms.

We come to the following conclusion: the correspondence of equipollence is defined by an *arbitrary system of skew-symmetric forms ω^j_i*.

82. Space with Euclidean connection. Suppose now that a certain equipollence is given, i.e., there is given a law of correspondence of vectors at a point M and at a neighboring point N. Then the scalar product of vectors is preserved,

$$\mathbf{X} \cdot \mathbf{Y} = \mathbf{X}' \cdot \mathbf{Y}'.$$

In fact, from conditions 1° and 2°, it follows that

$$(\mathbf{X}+\lambda\mathbf{Y})^2 = \mathbf{X}^2 + \lambda^2\mathbf{Y}^2 + 2\lambda\mathbf{X}\cdot\mathbf{Y}.$$

But from condition 1°,

$$\mathbf{X}^2 = (\mathbf{X}')^2, \ \ \mathbf{Y}^2 = (\mathbf{Y}')^2.$$

As a result, we have

$$\mathbf{X}\cdot\mathbf{Y} = \mathbf{X}'\cdot\mathbf{Y}'.$$

Preservation of the scalar product (and preservation of norms of vectors) implies preservation of angles between corresponding vectors.

Note that we can define a position of the point N with respect to the frame associated with the point M by means of the components ω^i of translation. If we fix a law of equipollence, then we can represent the points M and N and vectors emanating from M and N in the same Euclidean space. Two "equipollent" vectors become *really equipollent* (parallel) in this Euclidean space.

Thus, we have defined an *Euclidean connection* in a "generalized space", i.e., as in the Euclidean space, we have connected neighborhoods of two infinitesimally close points M and N. In general, for arbitrary points M and N, this is impossible. However, two points A and B that are not infinitesimally close can be connected by a *certain* path AB.

Then we can represent a neighborhood of a point M_1, which is infinitesimally close to the point A on the line AB. Next we can move from M_1 to M_2, and so on, step-by-step by the same method. (Note that the correspondence obtained depends on the choice of a path AB.)

How is the passage to the limit realized effectively?

83. Euclidean space of conjugacy. Suppose that a point μ, representing a variable point M of the arc AB, moves along an arc $\alpha\beta$ representing the arc AB. Then for a frame at the point μ, we have

$$\left\{\begin{aligned} d\mu &= \omega^1\mathbf{i}_1 + \omega^2\mathbf{i}_2 + \ldots + \omega^n\mathbf{i}_n, \\ d\mathbf{i}_i &= \omega_i^k\mathbf{i}_k. \end{aligned}\right. \tag{15.21}$$

If the point M describes the arc AB in such a way that its coordinates are represented by continuously differentiable functions (of class C^1) of a parameter t, then

$$\left\{\begin{aligned} \omega^i &= p^i dt, \\ \omega_i^j &= p_i^j dt, \end{aligned}\right. \tag{15.22}$$

where for a fixed path AB, the quantities p^i and p_i^j are completely determined functions of the independent variable t. Substituting these values into equations

(15.21), we obtain the Cauchy system

$$\begin{cases} \dfrac{d\mu}{dt} = p^k\,\mathbf{I}_k, \\ \dfrac{d\mathbf{i}_i}{dt} = p_i^k\,\mathbf{i}_k. \end{cases} \tag{15.23}$$

If we integrate this system, then we come to the *Euclidean space of conjugacy* (see No. **75**).

Choosing a certain Euclidean connection, we can extend the tensor analysis to this connection defining the absolute differential of a vector by the formulas for the contravariant and covariant vectors (in an orthonormal frame these formulas coincide):

$$\begin{cases} DX^i = dX^i + X^k\omega_k^i, \\ DX_i = dX_i - X_k\omega_i^k. \end{cases} \tag{15.24}$$

84. Absolute exterior differential. The most important moment is the extension of the notion of absolute differentiation of differential forms to the space with Euclidean connection.

In a generalized manifold, one cannot add vectors with different initial points, if these points are not connected by certain paths.

Consider a point A inside the domain in question and take a family of paths connecting the point A with different points of the domain. Then we can consider integrals over surfaces, volumes, etc.

In fact, suppose that a vector $(\widetilde{\omega}^i)$ is associated with a point M of a surface S. This vector, after being transferred to the point A along a path MA by means of equipollence, becomes

$$\xi^i = \alpha_k^i\widetilde{\omega}^k.$$

The sum of these vectors on a p-dimensional surface S is represented by the integral

$$\underbrace{\int\cdots\int}_{(p)}\xi^i = \underbrace{\int\cdots\int}_{(p)}\alpha_k^i\widetilde{\omega}^k.$$

Applying the generalized Gauss theorem to this integral, we represent this integral in the form

$$\underbrace{\int\cdots\int}_{(p+1)}(\alpha_k^i d\widetilde{\omega}^k + d\alpha_k^i \wedge \widetilde{\omega}^k). \tag{15.25}$$

Now we restrict ourselves to a domain that is sufficiently small in order to be able to consider only an element of the integral.

We will see that under these conditions the result does not depend on the choice of paths.

In fact, the general formula

$$\xi^i = X^k \alpha^i_k$$

shows that at the point A, where $\xi^i = X^i$, all α^i_k, except α^i_i (i not summed), vanish,

$$\alpha^i_k = 0, \quad k \neq i, \quad \alpha^i_i = 1 \quad (i \text{ not summed}).$$

Thus the integrand in (15.15) reduces to the sum

$$D\tilde{\omega}^i = d\tilde{\omega}^i + d\alpha^i_k \wedge \tilde{\omega}^k.$$

At a point M, which is infinitesimally close to the point A, we have

$$\xi^i = X^i + d\alpha^i_k X^h.$$

On the other hand,

$$X^i = \xi^i + \omega^i_k \xi^k.$$

Hence

$$d\alpha^i_k = \omega^i_k$$

and

$$D\tilde{\omega}^i = d\tilde{\omega}^i + \omega^i_k \wedge \tilde{\omega}^k. \tag{15.26}$$

This generalizes the formula for the absolute exterior differential in the Euclidean space.

Similarly we have

$$D\tilde{\omega}^j_i = d\tilde{\omega}^j_i - \omega^k_i \wedge \tilde{\omega}^k_j + \omega^j_k \wedge \tilde{\omega}^k_i. \tag{15.27}$$

85. Torsion of the manifold. Take an infinitesimally close contour around the point A. Let M and M' be two infinitesimally close points on the contour. Associate with the point M an infinitesimally small vector $\overrightarrow{ds} = \overrightarrow{MM'}$. Its components are

$$\tilde{\omega}^i = \omega^i.$$

Take the sum of all these vectors. Because the contour is infinitesimally small, we can replace this sum by one vector. In Euclidean space, this sum vanishes. Here we have

$$D\omega^i = d\omega^i + \omega^i_k \wedge \omega^k = d\omega^i - \omega^k \wedge \omega^i_k = \Omega^i. \tag{15.28}$$

This sum can be equal to zero—*this is an intrinsic property of the space*, since for all decompositions of ds^2 into a sum of squares (i.e., for any choice of ω^i), this sum is zero.

In order to satisfy this property, we need to choose ω_i^j such that

$$d\omega^i = \omega^k \wedge \omega_k^i.$$

We saw that this is always possible to achieve, and in only one way.

This is one of the possible Euclidean connections for ds^2. In fact, this was Riemann's choice of connection. This choice implies that the sum of vectors of a closed contour around a point is equal to zero.

However, this connection is not the only possible connection.

If one considers the general formula

$$d\omega^i = \omega^k \wedge \omega_k^i + \Omega^i,$$

where ω_k^i depend on secondary parameters v^α (defining a decomposition of ds^2 into a sum of squares), then the quadratic form Ω^i does not depend on these parameters, and hence it does not depend on the forms ω_k^i. The form Ω^i defines the *torsion* of the manifold.

86. Structure equations of a space with Euclidean connection. Let us investigate now how the structure equations (II$_2$),

$$d\omega_i^j = \omega_i^k \wedge \omega_k^j, \tag{II$_2$}$$

will be changed in the new connection.

Associate with a point M of a cycle Γ a vector $\mathbf{X}$ and consider the integral

$$\int\limits_\Gamma D\mathbf{X}.$$

In the Euclidean space this integral vanishes.

For an arbitrary connection, the components of $D\mathbf{X}$ are

$$\widetilde{\omega}^i = dX^i + X^k \omega_k^i. \tag{15.29}$$

Applying formula (15.26) for the absolute exterior differential to form (15.29), we obtain

$$\begin{aligned} D\widetilde{\omega}^i &= dX^k \wedge \omega_k^i + X^k d\omega_k^i + \omega_k^i \wedge (dX^k + X^h \omega_h^k) \\ &= X^k (d\omega_k^i + \omega_h^i \wedge \omega_k^h). \end{aligned}$$

Set

$$d\omega_k^i - \omega_k^h \wedge \omega_h^i = \Omega_k^i.$$

Then

$$\int D\mathbf{X}^i = \iint X^k \Omega_k^i.$$

The quadratic forms Ω_k^i are skew-symmetric. They define a rotation which gives to the vector X the variation $\int D\mathbf{X}$. Thus, in general, we have

$$d\omega^i = \omega^k \wedge \omega_k^i + \Omega^i, \tag{15.30}$$

$$d\omega_i^j = \omega_i^k \wedge \omega_k^j + \Omega_i^j. \tag{15.31}$$

87. Translation and rotation associated with a cycle. As our paths AM, we take the arcs AM of the cycle in question and develop this cycle on the line $\alpha\mu\alpha'$ of the Euclidean space (Fig. 5).

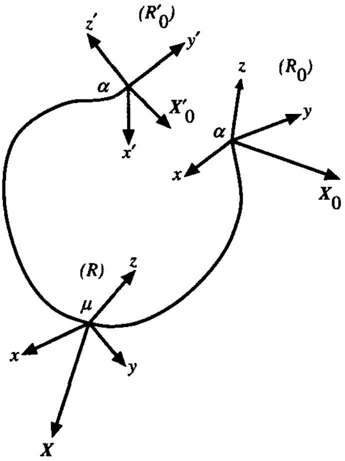

Fig. 5

A vector $\mathbf{X}$ attached to the point A is mapped into a vector $\mathbf{X}_0$ emanating from the point α and into a vector $\mathbf{X}'_0$ emanating from the point α'. When we move from M to M', we take $\mathbf{X}'$ at μ', $\mathbf{X}$ at μ, and compute

$$D\mathbf{X} = \mathbf{X}' - \mathbf{X},$$

i.e., in the Euclidean connection, we compute the ordinary difference $\mathbf{X}' - \mathbf{X}$, without moving to the point α. Thus,

$$\int D\mathbf{X},$$

is an ordinary integral for the path $\alpha\mu\alpha'$, i.e., it is the difference $\mathbf{X}'_0 - \mathbf{X}_0$. We see that this result depends on a field value at the point A (dX^k disappears in the computation).

Next we move from the vector $\mathbf{X}_0$ to the vector $\mathbf{X}'_0$ by means of a simple infinitesimal rotation which takes the frame (R_0) attached to the point α into the frame (R'_0) attached to the point α', i.e., it makes $\mathbf{X}_0$ parallel to $\mathbf{X}'_0$ (since the coordinates of $\mathbf{X}_0$ with respect to (R_0) are the same as the coordinates of $\mathbf{X}'_0$ with respect to (R'_0)).

The quantities Ω_i^j are the components in (R_0') of an infinitesimally small rotation making $\mathbf{R}_0$ parallel to $\mathbf{R}_0'$. Similarly, the quantities Ω^i are the components in (R_0') of an infinitesimally small translation transferring α to α'.

Thus, the displacement taking (R_0) to (R_0') has components Ω^i and Ω_i^j.

This displacement vanishes in the Euclidean space. The *inverse* displacement (i.e., the displacement taking (R_0') to (R_0)) is called the displacement *associated with the cycle.*

Consider a field of equipollent vectors. In the Euclidean connection, the vector $\mathbf{Y}(\alpha')$ is equipollent in an ordinary sense (equal) to the vector $\mathbf{X}_0$. At the same time an observer of a Riemannian manifold considers the vector $\mathbf{X}_0$, which is not equipollent to the vector $\mathbf{Y}$, as the initial vector. The variation is $\mathbf{Y} - \mathbf{X}_0'$, i.e., the *rotation* Ω_i^j *associated with the cycle.*

Thus, the rotation associated with a cycle is the rotation undergone by a vector which is transferred along a cycle equipollently.

The associated rotation defines the *curvature*, and the associated translation defines the *torsion* at the point A.

88. The Bianchi identities. Consider structure equations (15.30) and (15.31) of the space with Euclidean connection.

Here

$$\Omega^i = R^i_{[jk]}\omega^j \wedge \omega^k, \quad \Omega_i^j = R^j_{i[kh]}\omega^k \wedge \omega^h,$$

where

$$R^i_{[jk]} = R^i_{jk} - R^i_{kj}, \quad R^j_{i[kh]} = R^j_{ikh} - R^j_{ihk}.$$

In order to obtain the Bianchi identities, we apply exterior differentiation to equations (15.30) and (15.31):

$$0 = d\omega^k \wedge \omega_k^i - \omega^k \wedge \omega_k^i + d\Omega^i,$$
$$0 = d\omega_i^k \wedge \omega_k^j - \omega_i^k \wedge d\omega_k^i + d\Omega_i^j.$$

In ordinary Euclidean space, these equations are identically satisfied. This implies that if we substitute the values of $d\omega^i$ and $d\omega_i^j$ from (15.30) and (15.31) into the last equations, all the terms, except those containing the forms Ω^i and Ω_i^j, must cancel out:

$$0 = \Omega^k \wedge \omega_k^i - \omega^k \wedge \Omega_k^i + d\Omega^i, \tag{15.32}$$

$$0 = \Omega_i^k \wedge \omega_k^j - \omega_i^k \wedge \Omega_k^i + d\Omega_i^j. \tag{15.33}$$

This is the first group of the Bianchi identities written for the space with Euclidean connection.

89. Theorem of preservation of curvature and torsion. We turn now to the interpretation of equations (15.32) and (15.33). Start from equations (15.33). They show that the absolute differential of the form Ω_i^j is equal to zero.

From equations (15.26), the absolute differential of the form $\widetilde{\omega}^i$ is

$$D\widetilde{\omega}^i = d\widetilde{\omega}^i + \omega^i_k \wedge \widetilde{\omega}^k.$$

Similarly, the absolute differential of the form $\widetilde{\omega}^j_i$ is

$$D\widetilde{\omega}^j_i = d\widetilde{\omega}^j_i - \omega^k_i \wedge \widetilde{\omega}^j_k + \omega^j_k \wedge \widetilde{\omega}^k_i.$$

Applying the last formula to the form $\widetilde{\Omega}^j_i$ and using (15.33), we find that

$$D\Omega^j_i = d\Omega^j_i - \omega^k_i \wedge \Omega^j_k + \omega^j_k \wedge \Omega^k_i = 0.$$

In fact, in the last formula, the first sum is the same as in (15.33). As to the second sum, we have $\omega^j_k \wedge \Omega^k_i = \Omega^k_i \wedge \omega^j_k$, since the form Ω^k_i is of even order, and this permutation of factors does not change the sign in the product.

Thus, Ω^j_i is the sum of bivectors (skew-symmetric tensors). Take a volume V bounded by a surface S. Consider bivectors Ω^j_i applied to the surface S. Their sum is equal to zero. This follows from equations (15.33) by means of the Gauss theorem:

$$\iint\limits_S \Omega^j_i = \iiint\limits_V d\,\Omega^j_i.$$

Now we turn to equations (15.32). The absolute differential of the form Ω^i is

$$D\,\Omega^i = d\,\Omega^i + \Omega^k \wedge \omega^i_k.$$

From equations (15.32), it follows that

$$D\,\Omega^i = \omega^k \wedge \Omega^i_k.$$

Consider, for example a three-dimensional space and an oriented element of a surface (i.e., an element with a direction of an infinitesimally small cycle). To every cycle, there are the corresponding translation Ω^i and the rotation Ω^j_i with components

$$\Omega^1,\ \Omega^2,\ \Omega^3;\ \Omega^3_2,\ \Omega^1_3,\ \Omega^2_1.$$

The rotation Ω^j_i can be represented by a vector $(\widetilde{\omega}^1, \widetilde{\omega}^2, \widetilde{\omega}^3)$, and the translation Ω^i can be represented as the moment of a pair.

Thus, on a surface, a double system of vectors is formed. Consider the sum of all vectors and all pairs. We need to connect a point A with all points M of a surface by certain paths.

If (X^1, X^2, X^3) is a vector, then we can transfer it to the point A by the formula

$$\xi^i = a^i_k X^k.$$

The components of a pair can be found from the matrix

$$\begin{pmatrix} x & y & z \\ a^1_k\widetilde{\omega}^k & a^2_k\widetilde{\omega}^k & a^3_k\widetilde{\omega}^k \end{pmatrix},$$

and they are

$$
\begin{gathered}
ya^3_k\tilde{\omega}^k - za^2_k\tilde{\omega}^k,\\
za^1_k\tilde{\omega}^k - xa^3_k\tilde{\omega}^k,\\
xa^2_k\tilde{\omega}^k - ya^1_k\tilde{\omega}^k,
\end{gathered}
$$

where x, y, z are the coordinates of a point M with respect to the trihedron (R_0).

The sum of the vectors vanishes by means of equations (15.32). The sum of the pairs is

$$
\begin{aligned}
\iint\limits_S [a^1_1\Omega^1 &+ a^1_2\Omega^2 + a^1_3\Omega^3 + y(a^3_1\Omega^3_2 + a^3_2\Omega^1_3 + a^3_3\Omega^2_1)\\
&-z(a^2_1\Omega^3_2 + a^2_2\Omega^1_3 + a^2_3\Omega^2_1) + \dots].
\end{aligned}
$$

The integral along the entire surface reduces to the integral over the volume

$$
\begin{aligned}
\iiint\limits_V [a^1_1 d\Omega^1 &+ da^1_1 \wedge \Omega^1 + \dots + yd(a^3_1\Omega^3_2 + \dots)\\
&+dy \wedge (a^3_1\Omega^2_3 + \dots) - \dots].
\end{aligned}
$$

If a volume is very small, then by setting

$$a^1_1 = 1,\ \ a^2_1 = a^3_1 = 0,\ \ da^1_1 = 0,\ \ da^k_i = \omega^k_i,\ \ y = z = 0,\ \ dy = \omega^2,\ \ dz = \omega^3, \dots ,$$

we obtain

$$\iiint\limits_V (d\Omega^1 + \omega^1_k \wedge \Omega^k + \omega^2 \wedge \Omega^2_1 - \omega^3 \wedge \Omega^1_3).$$

But by means of the first equation of (15.32), we have

$$d\Omega^1 + \omega^1_k \wedge \Omega^k = d\Omega^1 + \omega^1_k \wedge \Omega^k - \omega^2 \wedge \Omega^1_2 - \omega^3 \wedge \Omega^1_3 = 0.$$

Thus, we have proved the following result.

Theorem 2. *In a Riemannian manifold with Euclidean connection, to a small volume there correspond both vectors and pairs, defining translations and rotations associated with a cycle on a surface. Geometrically, the sum of vectors and pairs is equal to zero.*

In mechanics one can find an interpretation in terms of the elastic forces acting on an area element.

Chapter 16

Riemannian Curvature of a Manifold

90. The Bianchi identities in a Riemannian manifold. The point of view of Riemann himself corresponds to a torsion-free connection,

$$\Omega^i = 0.$$

Now, the Bianchi identities take the form

$$\omega^k \wedge \Omega_k^i = 0, \tag{16.1}$$

$$\Omega_i^k \wedge \omega_k^j - \omega_i^k \wedge \Omega_k^j + d\Omega_i^j = 0. \tag{16.2}$$

The first of these identities show that there are no moments of pairs since the translation Ω^i is absent, and the second one shows that the sum of vectors vanishes (see No. **89**).

We decomposed ds^2 into a sum of squares and chose the unique forms ω_k^i in such a way that

$$d\omega^i = \omega^k \wedge \omega_k^i, \tag{16.3}$$

$$d\omega_i^j = \omega_i^k \wedge \omega_k^j + \Omega_i^j. \tag{16.4}$$

Is it possible to determine the forms ω_k^i independently of the choice of axes? This determination does not depend on the method of decomposition of ds^2 into a sum of squares. Take the most general decomposition of ds^2 into a sum of squares. The forms ω_i^j depend on the variables $u^1, u^2, \dots, u^n$ and on parameters $v^1, v^2, \dots, v^{\frac{n(n-1)}{2}}$ defining the method of decomposition. Obviously, Ω_{ij} can depend on both, ω^i and ω_i^j. We prove that Ω_{ij} depend only on ω^i. This follows from our Theorem 1 in No. **79**. We will prove this independently of this theorem.

From equations (15.31), we have

$$\Omega_i^j + \Omega_j^i = 0.$$

Denote the forms ω_{ij} by ω_α with Greek indices.

In general, the quadratic forms Ω_{ij} depend on both ω^i and ω_i^j. We can set

$$\Omega_{ki} = a_{ki[hl]}\, \omega^h \wedge \omega^l + b^\alpha_{kil}\, \omega^l \wedge \omega_\alpha + c^{[\alpha\beta]}_{ki}\, \omega_\alpha \wedge \omega_\beta,$$

where

$$a_{ki[hl]} = -a_{ki[lh]},$$
$$c^{[\alpha\beta]}_{ki} = -c^{[\beta\alpha]}_{ki}.$$

Substituting this expression for Ω_{ki} into equations (16.1), we find that

$$\omega^k \wedge \Omega_{ki} = a_{ki[hl]}\, \omega^k \wedge \omega^h \wedge \omega^l + b^\alpha_{kil}\, \omega^k \wedge \omega^l \wedge \omega_\alpha + c^{[\alpha\beta]}_{ki}\, \omega^k \wedge \omega_\alpha \wedge \omega_\beta.$$

Firstly, note that in the last sum, all terms contain different combinations of the basis forms $\omega^k, \omega_\alpha, \omega_\beta$, since the summation is carried over the combinations of α and β, and as a result, there are no similar terms. Thus,

$$c^{[\alpha\beta]}_{ki} = 0,$$

and the form Ω_{ki} does not contain terms with the products $\omega_\alpha \wedge \omega_\beta$.

Secondly, in the second sum for the triple of basis forms $\omega^k, \omega^l, \omega_\alpha$, two combinations

$$b^\alpha_{kil}\, \omega^k \wedge \omega^l \wedge \omega_\alpha + b^\alpha_{lik}\, \omega^l \wedge \omega^k \wedge \omega_\alpha$$

are possible. It follows that there is the symmetry in two lower indices:

$$b^\alpha_{kil} = b^\alpha_{lik}. \tag{16.5}$$

On the other hand, since the forms Ω_{ki} are skew-symmetric, we have

$$b^\alpha_{kil} = -b^\alpha_{ikl}. \tag{16.6}$$

Applying transformations (16.5) and (16.6) in turn, we obtain

$$b^\alpha_{kil} = b^\alpha_{lik} = -b^\alpha_{ilk} = -b^\alpha_{kli} = b^\alpha_{lki} = b^\alpha_{ikl} = -b^\alpha_{kil}.$$

It follows that

$$b^\alpha_{kil} = 0,$$

and the forms Ω_{ki} do not depend on the forms ω_α.

91. The Riemann–Christoffel tensor. From the previous section, we have

$$\Omega_i^j = R_i{}^j{}_{[kh]}\omega^k \wedge \omega^h. \tag{16.7}$$

The coefficients $R_i{}^j{}_{[kh]}$ constitute a tensor, since if we contract these quantities with the vectors ω^k and ω^h, we obtain the tensorial differential form Ω_{ij}. This tensor is called the *Riemann–Christoffel tensor.*

Structure equations (16.3) and (16.4) can be written now in the form

$$d\omega^i = \omega^k \wedge \omega^i_k, \tag{16.8}$$

$$d\omega^j_i = \omega^k_i \wedge \omega^j_k + R_i{}^j{}_{[kh]}\omega^k \wedge \omega^h. \tag{16.9}$$

If we substitute the values of the forms Ω_α from (16.7) into the first Bianchi identities (16.1), the latter give

$$R_k{}^i{}_{hl}\omega^k \wedge \omega^h \wedge \omega^l = 0.$$

In order to collect similar terms, we cycle these equations with respect to the three lower indices. Equating the coefficients obtained to zero, we find that

$$R_k{}^i{}_{hl} + R_h{}^i{}_{lk} + R_l{}^i{}_{kh} = 0,$$

or

$$(i) = R_{ikhl} + R_{ihlk} + R_{ilkh} = 0. \tag{16.10}$$

If we choose four arbitrary numbers i, k, h, l among $1, 2, \dots, n$, then there will be a few dependencies among the components R_{ikhl} with the chosen indices. These indices are split into two pairs, i, k and h, l.

1°. *Under permutation of indices of one pair, the quantity R_{ikhl} changes its sign.* For the first pair i, k, this follows from the skew-symmetry of the forms $\Omega_i{}^k$, and for the second pair h, l this follows from the accompanying permutation of factors ω^h, ω^l in the exterior product $\omega^h \wedge \omega^l$ and the invariance of the left-hand side Ω^i_k in (16.7).

2°. *Under permutation of pairs of indices, the quantity R_{ikhl} is not changed.* To prove this, consider equations (16.10) and equations obtained from these by the cyclic permutation of four indices i, k, h, l:

$$\begin{aligned}
(i) &= R_{ik,hl} + R_{ih,lk} + R_{il,kh} = 0,\\
(k) &= R_{kh,li} + R_{kl,ih} + R_{ki,hl} = 0,\\
(h) &= R_{hl,ik} + R_{hl,ik} + R_{hk,li} = 0,\\
(l) &= R_{li,kh} + R_{li,kh} + R_{lh,ik} = 0.
\end{aligned}$$

Then

$$\frac{1}{2}[(i) + (k) - (h) - (l)] = R_{khli} - R_{likh} = 0. \tag{16.11}$$

This proves property 2°.

We turn now to the second group (16.2) of the Bianchi identities:

$$d\Omega_i^j + \Omega_i^k \wedge \omega_k^j - \omega_i^k \wedge \Omega_k^j = 0.$$

Substituting Ω_i^j from (16.7) into these identities, we obtain

$$dR_i{}^j{}_{kh} \wedge \omega^k \wedge \omega^h + R_i{}^j{}_{kh}\, \omega^i \wedge \omega_i^k \wedge \omega^h - R_i{}^j{}_{kh}\, \omega^k \wedge \omega^l \wedge \omega_i^h$$
$$+ R_i{}^k{}_{lh}\, \omega^l \wedge \omega^h \wedge \omega_k^j - R_k{}^j{}_{lh}\, \omega_i^k \wedge \omega^l \wedge \omega^h = 0.$$

Changing the summation indices, we have

$$(dR_i{}^j{}_{kh} - R_i{}^j{}_{lh}\, \omega_k^l - R_i{}^j{}_{kl}\, \omega_h^i + R_i{}^l{}_{kh}\, \omega_l^j - R_l{}^j{}_{kh}\, \omega_i^l) \wedge \omega^k \wedge \omega^h = 0.$$

Using the notation D for the absolute differential, we get

$$DR_i{}^j{}_{kh} \wedge \omega^k \wedge \omega^h = 0,$$

or

$$R_i{}^j{}_{kh|l}\omega^l \wedge \omega^k \wedge \omega^h = 0.$$

Cycling three indices l, k, h and equating the coefficients to zero, we obtain the second group of conditions for the covariant derivatives of the Riemann–Christoffel tensor:

$$R_i{}^j{}_{kh|l} + R_i{}^j{}_{hl|k} + R_i{}^j{}_{lk|h} = 0. \qquad (16.12)$$

It follows that the number of all components of the Riemann–Christoffel tensor is:

$$\frac{n(n-1)}{2} \text{ of type } R_{ij,ij};$$
$$\frac{n(n-1)(n-2)}{2} \text{ of type } R_{ij,ik};$$
$$2\frac{n(n-1)(n-2)(n-3)}{4!} \text{ of type } R_{ij,kh};$$

altogether, we have

$$\frac{n^2(n^2-1)}{12}$$

different components.

It is always possible to find a Riemannian manifold corresponding to arbitrary values of these quantities.

92. Riemannian curvature. At a point A, consider a bivector defined by the coordinates $p^{ij} = -p^{ji}$. This is an oriented element of a surface. A certain rotation Ω_{ij} is associated with this element, and since

$$\omega^k \wedge \omega^h = p^{kh},$$

we have

$$q_{ij} = -R_{ij[kh]}p^{kh}.$$

Consider now the scalar product

$$p^{ij}q_{ij} = R_{ij,kh}p^{ij}p^{kh},$$

where $q_{ij} = -\Omega_{ij}$ are components of the associated rotation. The *Riemannian curvature* at the point A in the planar direction of the above bivector is defined by the formula

$$K = \frac{p^{ij}q_{ij}}{\sum\limits_{(i,j)}(p^{ij})^2} = -\frac{R_{ij,kh}p^{ij}p^{kh}}{\sum\limits_{(i,j)}(p^{ij})^2}. \tag{16.13}$$

93. The case $n = 2$. We have only one quadratic form, namely,

$$\Omega_1^2 = R_1{}^2{}_{12}\omega^1 \wedge \omega^2 = -K\omega^1 \wedge \omega^2. \tag{16.14}$$

This is the Riemannian curvature of the manifold.

We saw that a rotation is associated with a cycle. If $d\sigma$ is an area bounded by a cycle, then a vector $\mathbf{X}$, remaining equipollent to itself under traveling the cycle, will not return to the initial position after the cycle is complete. This vector takes new position $\mathbf{X}'$ forming an angle

$$K\,d\sigma$$

with the original position.

The structure equations are

$$\begin{cases} d\omega^1 = \omega^2 \wedge \omega_2^1, \\ d\omega^2 = \omega^1 \wedge \omega_1^2, \\ d\omega_1^2 = -K\,\omega^1 \wedge \omega^2. \end{cases}$$

In general, the Riemannian curvature is a function of a point.

The simplest case is the space of constant curvature,

$$K = \text{const}.$$

An example of such a space is a sphere in an ordinary space. Its curvature $K = \frac{1}{R^2}$, where R is the radius of the sphere.

In fact, let R be a radius of a sphere, and O be its center. Associate with the point O trihedrons O, x_1, x_2, x_3 depending on three parameters.

If the point O is fixed, then a trihedron rotates with rotation components

$$\varpi_{12},\quad \varpi_{23},\quad \varpi_{31}.$$

If M is the common point of the third axis of the trihedron and the sphere, then

$$\overrightarrow{OM} = R\mathbf{I}_3$$

is the position vector of the point M of the sphere.

For the trihedrons in question, we have the following structure equations and the equations of infinitesimal displacement of axes:

$$\begin{cases} d\varpi_{23} = \varpi_{21} \wedge \varpi_{13}, & d\mathbf{I}_1 = \varpi_{12}\mathbf{I}_2 + \varpi_{13}\mathbf{I}_3, \\ d\varpi_{31} = \varpi_{32} \wedge \varpi_{21}, & d\mathbf{I}_2 = \varpi_{21}\mathbf{I}_1 + \varpi_{23}\mathbf{I}_3, \\ d\varpi_{12} = \varpi_{13} \wedge \varpi_{32}, & d\mathbf{I}_3 = \varpi_{31}\mathbf{I}_1 + \varpi_{32}\mathbf{I}_2. \end{cases} \tag{16.15}$$

If R is constant, then the displacement of the point M is equal to $d\mathbf{I}_3$ multiplied by R:

$$d\mathbf{M} = R\,(\varpi_3^1\mathbf{I}_1 + \varpi_3^2\mathbf{I}_2).$$

Thus, for the sphere, we have

$$\omega^1 = R\varpi_3^1,\quad \omega^2 = R\varpi_3^2,\quad \omega_1^2 = \varpi_1^2.$$

The structure equations are

$$\begin{aligned} d\omega^1 &= R\,d\varpi_{31} = R\varpi_{32} \wedge \varpi_{21} = \omega^2 \wedge \varpi_{21}, \\ d\omega^2 &= \omega^1 \wedge \varpi_{12}, \\ d\omega_1^2 &= d\varpi_{12} = \varpi_{13} \wedge \varpi_{32} = -\frac{1}{R^2}\,\omega^1 \wedge \omega^2. \end{aligned}$$

It follows that the curvature $K = \frac{1}{R^2}$.

This can be generalized to arbitrary dimension. All of these results can be obtained by considering a line element of a sphere. It has the form

$$ds^2 = R^2\,d\theta^2 + R^2 \sin^2\theta\,d\varphi^2,$$

where $\frac{\pi}{2} - \theta$ is the latitude, and φ is the longitude. Thus,

$$\omega^1 = R\,d\theta,\quad \omega^2 = R\,\sin\theta\,d\varphi.$$

Applying exterior differentiation, we obtain

$$d\omega^1 = 0,\quad d\omega^2 = R\,\cos\theta\,d\theta \wedge d\varphi.$$

Since

$$d\omega^1 = \omega^2 \wedge \omega_2^1, \quad d\omega^2 = \omega^1 \wedge \omega_1^2,$$

and hence

$$\omega_1^2 \wedge d\varphi = 0, \quad \omega_1^2 \wedge d\theta = \cos\theta\, d\varphi \wedge d\theta,$$

we find that

$$\omega_1^2 = \cos\theta\, d\varphi.$$

Further, we have

$$d\omega_1^2 = -\sin\theta\, d\theta \wedge d\varphi = -\frac{1}{R^2}\,\omega^1 \wedge \omega^2,$$

and thus the curvature $K = \frac{1}{R^2}$.

94. The case $n = 3$. Now equations (16.7) have the form

$$\begin{cases} \Omega_{23} = R_{23,23}\,\omega^2 \wedge \omega^3 + R_{23,31}\,\omega^3 \wedge \omega^1 + R_{23,12}\,\omega^1 \wedge \omega^2, \\ \Omega_{31} = R_{31,23}\,\omega^2 \wedge \omega^3 + R_{31,31}\,\omega^3 \wedge \omega^1 + R_{31,12}\,\omega^1 \wedge \omega^2, \\ \Omega_{12} = R_{12,23}\,\omega^2 \wedge \omega^3 + R_{12,31}\,\omega^3 \wedge \omega^1 + R_{12,12}\,\omega^1 \wedge \omega^2. \end{cases}$$

For brevity, denote $R_{23,23}$ by $-K_{11}$, $R_{31,31}$ by $-K_{12}$, and so on, replacing in each group of indices a pair of indices by a complementary index. Then we have

$$\begin{cases} \Omega_{23} = -K_{11}\,\omega^2 \wedge \omega^3 - K_{12}\,\omega^3 \wedge \omega^1 - K_{13}\,\omega^1 \wedge \omega^2, \\ \Omega_{31} = -K_{21}\,\omega^2 \wedge \omega^3 - K_{22}\,\omega^3 \wedge \omega^1 - K_{23}\,\omega^1 \wedge \omega^2, \\ \Omega_{12} = -K_{31}\,\omega^2 \wedge \omega^3 - K_{32}\,\omega^3 \wedge \omega^1 - K_{33}\,\omega^1 \wedge \omega^2. \end{cases}$$

The property $R_{ij,kh} = R_{kh,ij}$, yields the symmetry of K_{ij}:

$$K_{21} = K_{12}, \quad K_{31} = K_{13}, \quad K_{32} = K_{23}, \tag{16.16}$$

and the condition (16.12),

$$R_{i\ kh|l}^{\ j} + R_{i\ hl|k}^{\ j} + R_{i\ lk|h}^{\ j} = 0$$

takes the form

$$\sum_k K_{ik|k} = 0. \tag{16.17}$$

It should be pointed out that in equations (16.17), each of the first two indices represent a pair of complementary indices, and the third index (written on the right of the vertical line), the index of covariant differentiation, indicates the form ω^k in which the covariant derivative stands for a coefficient.

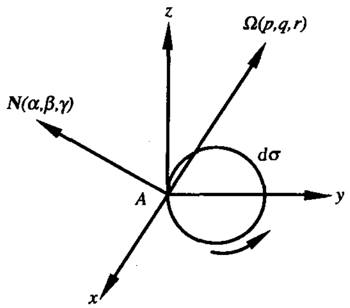

Fig. 6

95. Geometric theory of curvature of a three-dimensional Riemannian manifold. Suppose that a frame is connected with a point A and the element of surface $d\sigma$ passing through the point A (Fig. 6). Let $d\sigma$ be an oriented cycle, α, β, γ be the direction cosines of the normal, and $p d\sigma, q d\sigma, r d\sigma$ be the rotation associated with the cycle. We can always assume that $d\sigma$ is an infinitesimally small parallelogram with sides $\omega^i(d)$:

$$\begin{pmatrix} \omega^1(d) & \omega^2(d) & \omega^3(d) \\ \omega^1(\delta) & \omega^2(\delta) & \omega^3(\delta) \end{pmatrix}.$$

Then

$$\omega_2 \wedge \omega_3 = \alpha\, d\sigma.$$

Thus, if $\Omega(p, q, r)$ is the rotation associated with the cycle with components

$$p\, d\sigma, \quad q\, d\sigma, \quad r\, d\sigma,$$

then

$$\begin{cases} p\, d\sigma = K_{11}\, \alpha\, d\sigma + K_{12}\, \beta\, d\sigma + K_{13}\, \gamma\, d\sigma, \\ q\, d\sigma = K_{21}\, \alpha\, d\sigma + K_{22}\, \beta\, d\sigma + K_{23}\, \gamma\, d\sigma, \\ r\, d\sigma = K_{31}\, \alpha\, d\sigma + K_{32}\, \beta\, d\sigma + K_{33}\, \gamma\, d\sigma. \end{cases}$$

It follows that

$$\begin{cases} p = K_{11}\, \alpha + K_{12}\, \beta + K_{13}\, \gamma, \\ q = K_{21}\, \alpha + K_{22}\, \beta + K_{23}\, \gamma, \\ r = K_{31}\, \alpha + K_{32}\, \beta + K_{33}\, \gamma. \end{cases}$$

These formulas coincide with the formulas of the theory of elasticity which define the liquid pressure on a surface element.

Define the quadric-indicatrix (a surface of second order):

$$\Phi(x,y,z) = K_{11}x^2 + K_{22}y^2 + K_{33}z^2$$
$$+2K_{12}xy + 2K_{23}yz + 2K_{31}xz = 1.$$

The diametrical plane which is conjugate to the direction (α,β,γ) has the direction parameters

$$\frac{1}{2}\Phi'_\alpha,\ \frac{1}{2}\Phi'_\beta,\ \frac{1}{2}\Phi'_\gamma,\ \text{i.e., } p,\ q,\ r;$$
$$\Phi'_\alpha = \left.\frac{\partial\Phi}{\partial x}\right|_{x=\alpha,y=\beta,z=\gamma},\quad \Phi'_\beta = \left.\frac{\partial\Phi}{\partial y}\right|_{x=\alpha,y=\beta,z=\gamma},\quad \Phi'_\gamma = \left.\frac{\partial\Phi}{\partial z}\right|_{x=\alpha,y=\beta,z=\gamma}.$$

The equation of this plane is

$$x\Phi'_\alpha + y\Phi'_\beta + z\Phi'_\gamma = 0.$$

This implies the following result.

Theorem 1. *The vector representing the rotation associated with a surface element is normal to the diametrical plane which is conjugate to the direction of the surface normal. In order to find the magnitude of this rotation, it is sufficient to find its projection onto the direction* (α,β,γ).

Suppose that P is the common point of the quadric-indicatrix and the normal AP to a surface element. (A is a point at which the element is considered; this is the center of the quadric.)

We have

$$p\alpha + q\beta + r\gamma = \Phi(\alpha,\beta,\gamma) = \frac{1}{\overline{AP}^2}.$$

The *Riemannian curvature* at the point A in the direction of (α,β,γ) is equal to the projection of the rotation vector onto this direction: this is $\Phi(\alpha,\beta,\gamma)$ (Schur's definition).

The directions of the axes of the quadric-indicatrix are called the *principal directions* at the point A.

The rotation associated with an element normal to a principal direction takes place around this direction. If we take the coordinate axes as the quadric axes, then in the quadric equation, only squares remain. The coefficients in these squares are the *principal curvatures.* If the indicatrix is a sphere, then the principal curvatures are equal. In this case, the manifold is *isotropic* at a point.

96. Schur's theorem. *If a manifold is isotropic at each point, then the Riemannian curvature of the manifold is the same at all points.*

In fact, the vector Ω_{ij} is reduced to the form

$$-K\omega^i \wedge \omega^j.$$

The vanishing of its absolute exterior differential gives

$$dK \wedge \omega^i \wedge \omega^j = 0,$$

since

$$D\overline{\omega}_{ij} = d\overline{\omega}_{ij} + \omega_{ki} \wedge \overline{\omega}_{kj} + \omega_{kj} \wedge \overline{\omega}_{ik}.$$

All

$$D\overline{\omega}_{ij} = 0$$

by means of the second group of Bianchi's identities.

If

$$\overline{\omega}_{ij} = -K\,\omega^i \wedge \omega^j,$$

then

$$d\widetilde{\omega}_{ij} = -dK \wedge \omega^i \wedge \omega^j - K\,d\omega^i \wedge \omega^j + K\,d\omega^j \wedge \omega^i.$$

On the other hand, $D\overline{\omega}_{ij} = 0$ implies that

$$d\widetilde{\omega}_{ij} = -\omega_{ki} \wedge \overline{\omega}_{kj} - \omega_{kj} \wedge \overline{\omega}_{ik} = -K\,d\omega^i \wedge \omega^j + K\,d\omega^j \wedge \omega^i.$$

Thus,

$$dK \wedge \omega^i \wedge \omega^j = 0.$$

It follows from these equations that the differential dK depends linearly on ω^i and ω^j. But it does not depend on ω^i. Thus $dK = 0$, and $K = \text{const}$.

MECHANICAL INTERPRETATION. An ideal liquid in equilibrium, under action of internal forces only, is subject to a constant pressure at all points.

97. Example of a Riemannian space of constant curvature. Consider a rigid body rotating around a fixed point with velocity components p, q, r. If the ellipsoid of inertia is a sphere, then the kinetic energy has the form

$$2T = A\,(p^2 + q^2 + r^2),$$

and we have a Riemannian manifold with the line element

$$ds^2 = A\,(p^2 + q^2 + r^2)dt^2,$$

since

$$ds^2 = 2T\,dt^2.$$

Consider a coordinate trihedron invariantly connected with the rigid body in question. Suppose that $\widetilde{\omega}_{23}, \widetilde{\omega}_{31}, \widetilde{\omega}_{12}$ are the components of its rotation. We have

$$\widetilde{\omega}_{23} = p\,dt, \quad \widetilde{\omega}_{31} = q\,dt, \quad \widetilde{\omega}_{12} = r\,dt.$$

It follows that

$$ds^2 = A\,[(\widetilde{\omega}_{23})^2 + (\widetilde{\omega}_{31})^2 + (\widetilde{\omega}_{12})^2].$$

Since the rotation occurs in Euclidean space, we have

$$\begin{cases} d\omega_{23} = \omega_{21} \wedge \omega_{13}, \\ d\omega_{31} = \omega_{32} \wedge \omega_{21}, \\ d\omega_{12} = \omega_{13} \wedge \omega_{32}. \end{cases}$$

We can set

$$\begin{cases} \omega^1 = \sqrt{A}\,\omega_{23}, \\ \omega^2 = \sqrt{A}\,\omega_{31}, \\ \omega^3 = \sqrt{A}\,\omega_{12}. \end{cases}$$

This implies that

$$\begin{cases} d\omega^1 = -\dfrac{1}{\sqrt{A}}\,\omega^2 \wedge \omega^3, \\ d\omega^2 = -\dfrac{1}{\sqrt{A}}\,\omega^3 \wedge \omega^1, \\ d\omega^3 = -\dfrac{1}{\sqrt{A}}\,\omega^1 \wedge \omega^2. \end{cases}$$

Suppose that

$$\omega_{23} = \lambda\,\omega_1, \;\; \omega_{31} = \lambda\,\omega_2, \;\; \omega_{12} = \lambda\,\omega_3.$$

Then

$$d\omega^1 = -\omega^2 \wedge \omega_1^2 - \omega_3^1 \wedge \omega^3 = -2\lambda\,\omega^2 \wedge \omega^3.$$

Thus,

$$\lambda = \frac{1}{2\sqrt{A}}$$

and

$$\omega_{23} = \frac{1}{2\sqrt{A}}\,\omega_1, \;\; \omega_{31} = \frac{1}{2\sqrt{A}}\,\omega_2, \;\; \omega_{12} = \frac{1}{2\sqrt{A}}\,\omega_3.$$

It follows that

$$\begin{aligned} \Omega_{23} &= -d\omega_{23} - \omega_{21} \wedge \omega_{13}, \\ &= -\frac{1}{2A}\,\omega^2 \wedge \omega^3 + \frac{1}{4A}\,\omega^2 \wedge \omega^3 = -\frac{1}{4A}\,\omega^2 \wedge \omega^3. \end{aligned}$$

Finally, we have

$$K_{ij} = 0, \;\; i \neq j, \;\; K_{ii} = \frac{1}{4A} \;\; (i \text{ not summed}).$$

We have a space of constant Riemannian curvature $\frac{1}{4\sqrt{A}}$.

98. Determination of the Riemann–Christoffel tensor for a Riemannian curvature given for all planar directions.

Theorem 2. *If a Riemannian curvature is given for all planar directions emanating from a point A, then all components $R_{ij,kh}$ of the Riemann-Christoffel tensor can be found.*

Proof. Note that this is not obvious: the quantities p^{ij} are not arbitrary, since they are the components of a bivector and are connected by certain known relations. Thus, one cannot claim *a priori* that knowing the curvature

$$R_{ij,kh}p^{ij}p^{kh}$$

implies knowing the components $R_{ij,kh}$.

In order to prove the theorem, we need to show that if the equation

$$R_{ij,kh}p^{ij}p^{kh} = R'_{ij,kh}p^{ij}p^{kh}$$

holds for all p^{ij}, then this implies that

$$R_{ij,kh} = R'_{ij,kh}.$$

In other words, if we set

$$S_{ij,kh} = R_{ij,kh} - R'_{ij,kh},$$

then it is sufficient to prove that the equation

$$S_{ij,kh}\, p^{ij}p^{kh} = 0 \tag{16.18}$$

implies that

$$S_{ij,kh} = 0.$$

Introduce the vectors **X** and **Y** defining a bivector P with components

$$P^{ij} = X^iY^j - X^jY^i.$$

Then equation (16.18) takes the form

$$S_{ij,kh}\,(X^iY^j - X^jY^i)(X^kY^h - X^hY^k) = 0,$$

where all vectors X^i and Y^j are linearly independent. The last equation can be written as

$$S_{ij,kh}X^iY^jX^kY^h = 0.$$

In this sum (where the summation is carried out over all the indices i, j, k, and h), the term $(X^i)^2(Y^j)^2$ occurs only once. Thus, the coefficient of this term vanishes,

$$S_{ij,ij} = 0.$$

The term $(X^i)^2 Y^j Y^k$ occurs twice. Thus,

$$S_{ij,ih} + S_{ih,ij} = 0.$$

But using (16.11), we can easily prove that

$$S_{ij,ih} = S_{ih,ij}.$$

Hence,

$$S_{ij,ih} = S_{ih,ij} = 0.$$

Finally, the term $X^i X^k Y^j Y^h$ occurs four times and gives

$$S_{ij,kh} + S_{kj,ih} + S_{ih,kj} + S_{kh,ij} = 0,$$

or applying (16.11), we find that

$$2S_{ij,kh} + 2S_{ih,kj} = 0,$$

or

$$S_{ij,kh} = S_{ih,jk}.$$

Similarly,

$$S_{ik,hj} = S_{ij,kh}.$$

Thus, in the equations

$$S_{ij,kh} + S_{ik,hj} + S_{ih,jk} = 0,$$

which follows from (16.10), all terms are equal to one another. As a result, we have

$$S_{ij,kh} = 0.$$

99. Isotropic n-dimensional manifold. A manifold is called *isotropic* at a point A if the Riemannian curvature is the same in all directions, i.e., if

$$K = -\frac{R_{ij,kh}\, p^{ij} p^{kh}}{\sum\limits_{(i,j)} (p^{ij})^2}$$

and K does not depend on p^{ij}, or if

$$R_{ij,kh}\, p^{ij} p^{kh} + K \sum_{(i,j)} (p^{ij})^2 = 0$$

for all bivectors p^{ij}.

This reduces to Theorem 1 if we set

$$R'_{ij,ij} = -K, \;\; R'_{ij,kh} = 0.$$

As we proved, the components $R'_{ij,ij}$ must be equal to the corresponding components $R_{ij,ij}$.

Thus,

$$R_{ij,ij} = -K,$$

and all remaining components vanish,

$$R_{ij,kh} = 0.$$

Hence,

$$\Omega_{ik} = -K\omega^i \wedge \omega^j.$$

This is again Schur's theorem but now this theorem is extended to all values $n \geq 3$.

100. Curvature in two different two-dimensional planar directions. Let q_{ij} and q'_{ij} be rotations associated with two surface elements p^{ij} and p'^{ij}. We have

$$p^{ij} q'_{ij} = R_{ij,kh}\, p'^{kh} p^{ij}.$$

The number

$$-\frac{R_{ij,kh}\, p'^{kh} p^{ij}}{\sqrt{\sum\limits_{(i,j)} (p^{ij})^2}\sqrt{\sum\limits_{(i,j)} (p'^{ij})^2}}$$

is called the *mixed curvature* in two directions. The curvature K is a special case, when two directions coincide.

101. Riemannian curvature in a direction of arbitrary dimension. Until now we have considered only plane directions defined by bivectors.

Take now a three-dimensional element with which a system of trivectors

$$\Omega_{ijk} = \omega_i \wedge \Omega_{jk} + \omega_j \wedge \Omega_{ki} + \omega_k \wedge \Omega_{ij}$$

is associated. Consider a surface bounding this element, and attach a sliding (not free, as before) scalar bivector to each surface element.

The geometric sum of these bivectors gives a free trivector Ω_{ij}.

Consider the direction p^{ijk}, to which we attach a system of trivectors Ω_{ijk}, and consider the expression

$$K = -\frac{p^{ijk}\,\Omega_{ijk}}{\sqrt{\sum\limits_{(i,j,k)} (p^{ijk})^2}} = -\frac{p^{ijk}\, R_{ik,hl}\, p_i^{hl}}{\sqrt{\sum\limits_{(i,j,k)} (p^{ijk})^2}} = -\frac{R_{ik,hl}\, p^{ijk}\, p_i^{hl}}{\sqrt{\sum\limits_{(i,j,k)} (p^{ijk})^2}}.$$

This is the corresponding Riemannian curvature.

The Riemannian curvature in a four-dimensional direction is defined in a similar way:

$$K = -\frac{R_{ik,kh}\, p^{ij,\rho\sigma}\, p_{\rho\sigma}^{kh}}{\sqrt{\sum\limits_{(i,j,k)} (p^{ijk})^2}}.$$

102. Ricci tensor. Einstein's quadric. The important results are obtained for the dimension $n-1$.

An $(n-1)$-dimensional direction is defined by means of an $(n-1)$-vector, or by means of an orthogonal vector. If α_i are the direction cosines of the normal, we can set

$$p_{234\ldots n} = \alpha_1\, d\sigma, \quad p_{134\ldots n} = -\alpha_2\, d\sigma, \ldots \; .$$

Then, in the expression of the curvature, the numerator is

$$K_{[i,j]}\sigma^i\sigma^j,$$

where

$$K_{12} = R_1{}^k{}_{2k}, \quad K_{11} = -R_{23,23} - R_{34,34} - \ldots \; .$$

Define the *Ricci tensor*

$$R_{ij} = R_i{}^k{}_{jk}.$$

We have

$$K_{ij} = R_{ij}, \quad i \neq j,$$

$$K_{11} = R_{11} - R^{ij}_{\cdot\cdot,ij} = R_{11} - \frac{1}{2}\sum_i R_{ii}.$$

The tensor K_{ij} can be called the *Einstein tensor.*

We return to the notations of the case $n=3$. We can define the *Einstein quadric*

$$K_{ij}X^iX^j = 1$$

and the *isotropy of the second kind* (the Einstein quadric is a sphere). There is also a theorem similar to Schur's theorem.

The notion of a space of constant curvature of the second kind is more general (only $\frac{n(n-1)}{2}$ coefficients).

This page is intentionally left blank

Chapter 17

Spaces of Constant Curvature

103. Congruence of spaces of the same constant curvature. The structure equations of a space of constant curvature are

$$\begin{cases} d\omega^i = \omega^k \wedge \omega^i_k, \\ d\omega^j_i = \omega^k_i \wedge \omega^j_k - K\,\omega^i \wedge \omega^j. \end{cases} \tag{17.1}$$

All coefficients in these equations are constant for an arbitrary choice of an orthonormal frame.

Theorem 1. *If there exists a space of a given constant curvature K, then such a space is unique.*

This means the following: if there are two spaces with curvature K and line elements ds^2 and $d\sigma^2$, then in some domain by means of an appropriate change of variables, we can reduce ds^2 to coincide with $d\sigma^2$. Take a neighborhood of a point M_0 of one of these spaces and an arbitrary point M'_0 of the second space. Then we can superpose the neighborhood of the point M_0 on the second space in such a way that the point M_0 coincides with the point M'_0 and a frame (R_0) associated with the point M_0 coincides with a frame (R'_0) associated with the point M'_0.

Proof. Suppose that $u^1, \dots, u^N$, where $N = \frac{n(n+1)}{2}$, are parameters defining the most general frame at the point M_0, and $v^1, \dots, v^N$ are similar parameters at the point M'_0. At the point M_0, we have equations (17.1), and at the point M'_0, we have the similar equations

$$\begin{cases} d\overline{\omega}^i = \overline{\omega}^k \wedge \overline{\omega}^i_k, \\ d\overline{\omega}^j_i = \overline{\omega}^k_i \wedge \overline{\omega}^j_k - K\,\overline{\omega}^i \wedge \overline{\omega}^j. \end{cases} \tag{17.2}$$

Establish a correspondence between the points of two spaces by means of the equations

$$\begin{cases} \overline{\omega}^i(v, dv) = \omega^i(u, du), \\ \overline{\omega}_i^j(v, dv) = \omega_i^j(u, du), \end{cases} \tag{17.3}$$

where the v's must be considered as unknown functions of the u's. The system of equations (17.3) is completely integrable, since by equations (17.1) and (17.2), the equations

$$\begin{cases} d\overline{\omega}^i - d\omega^i = 0, \\ d\overline{\omega}_i^j - d\omega_i^j = 0 \end{cases} \tag{17.4}$$

are algebraic consequences of system (17.3).

In particular, system (17.4) admits solutions for which an initial system of values (u_0) corresponds to an arbitrary system of values (v_0), i.e., two arbitrary frames of the first and second family correspond to one another.

Since now

$$\begin{cases} v^1 = f^1(u^1, \dots, u^N), \\ \dots\dots\dots\dots\dots\dots\dots\dots \\ v^N = f^N(u^1, \dots, u^N), \end{cases}$$

we have a point correspondence between the two spaces.

In fact, the system of equations $\omega^i = 0$, $i = 1, \dots, n$, is completely integrable. Take $u^1, \dots, u^n$ as first integrals of this system. For constant values (u^i), we have $\omega^i = 0$, and the point M_0 of the first space is fixed. Thus, u^i are curvilinear coordinates of the first space. Take $v^1, \dots, v^n$ as those values of the first integrals of the system $\overline{\omega}^i = 0$ that correspond to the values (u^i) obtained in integrating of system (17.3). Since

$$\overline{\omega}^i = \omega^i, \tag{17.5}$$

v^i depend on $u^1, \dots, u^n$ only. To a point of the first space, there is a corresponding point of the second.

Finally, equations (17.5) imply the coincidence of the line elements,

$$ds^2 = \sum_i (\omega^i)^2 \text{ and } d\sigma^2 = \sum_i (\overline{\omega}^i)^2.$$

Corollary 2. *A space of constant curvature is applicable onto itself in an infinite number of ways: this space admits infinitely many motions (transformations preserving the distances). As with the Euclidean space, a space of constant curvature admits* ∞^N *displacements, where* $N = \frac{n(n+1)}{2}$.

REMARK. The spaces of constant curvature are the most general among the spaces admitting the group of motions. In fact, since the Riemannian curvature is defined by a line element ds^2, for displacements preserving ds^2, the Riemannian curvature is also preserved. In particular, a motion with a fixed arbitrary point A is possible. Thus, at this point A, the curvature in all directions is the same. Hence, the space is isotropic and has a constant curvature.

104. Existence of spaces of constant curvature. We pose this problem in another, more general form. The system of equations (17.1) is a particular case of a more general system of equations

$$d\omega^i = c^i_{[jk]}\omega^j \wedge \omega^k, \tag{17.6}$$

where

$$c^i_{[jk]} = c^i_{jk} - c^i_{kj}$$

are constants. The question is: does system (17.1) admit a solution ω^i ?

We obtain a necessary condition of existence of a solution, which is similar to the Bianchi identities, if we apply exterior differentiation to system (17.6):

$$0 = c^i_{[jk]}\,(d\omega^j \wedge \omega^k - \omega^j \wedge d\omega^k).$$

Changing in the second sum the summation indices $\binom{j\,k}{k\,j}$ and taking into account the fact that the coefficients $c^i_{[jk]} = c^i_{jk} - c^i_{kj}$ are skew-symmetric and the condition $\omega^j \wedge d\omega^k = d\omega^k \wedge \omega^j$ ($d\omega^k$ is of degree two), we obtain

$$0 = c^i_{[jk]}\, d\omega^j \wedge \omega^k.$$

Insert here the expression of $d\omega^i$ from formula (17.6). This gives

$$c^i_{[jk]}\, c^j_{[hl]}\, \omega^h \wedge \omega^j \wedge \omega^k = 0.$$

To collect similar terms, we make the circular substitution of indices h, l, k. This gives

$$(c^i_{[jk]}c^j_{[hl]} + c^i_{[jh]}c^j_{[lk]} + c^i_{[jl]}c^j_{[kh]})\,\omega^h \wedge \omega^j \wedge \omega^k = 0,$$

or finally

$$c^i_{[jk]}c^j_{[hl]} + c^i_{[jh]}c^j_{[lk]} + c^i_{[jl]}c^j_{[kh]} = 0. \tag{17.7}$$

Equations (17.6) are called the *structure equations of the group of transformations,* and equations (17.7) are the *conditions for the structure constants* $c^i_{[jk]}$ *of the group.* The group transformations are obtained from the equations

$$\omega^i(u, du) = \omega^i(v, dv), \quad i = 1, 2, \dots, r,$$

which, by equations (17.6), are completely integrable. Here (u^i) are the original coordinates of a point, and (v^i) are the coordinates of the transformed point.

We prove that conditions (17.7) are sufficient for the existence of r independent Pfaffian forms satisfying system (17.6). In group theory this corresponds to the third Sophus Lie theorem on existence of the group of transformations with given structure coefficients $c^i_{[jk]}$ satisfying conditions (17.7).

105. Proof of Schur. Suppose that we have a solution

$$\omega^i = A^i_k du^k,$$

where A^i_k are functions of independent variables u^k. Since the system of forms ω^i is linearly independent, the determinant of its coefficients is necessarily different from zero at the initial point:

$$\det(A^i_k) \neq 0 \text{ for } u^k = 0. \tag{17.8}$$

Introduce a redundant number $r+1$ variables instead of former r variables by setting

$$u^k = v^k t.$$

Then

$$\omega^i = A^i_k \, v^k \, dt + tA^i_k \, dv^k.$$

For $t = 0$, all coefficients in the differential dt are reduced to r functions

$$A^i_k(0) \, v^k,$$

that are independent by condition (17.8).

Define the quantities

$$a^i = A^i_k \, v^k, \tag{17.9}$$

which can be considered as new variables. So, now we have

$$\omega^i = a^i \, dt + \overline{\omega}^i(a, t, da), \tag{17.10}$$

where $\overline{\omega}^i$ are linear with respect to da^k and vanish if $t = 0$. We prove that for system (17.6), it is possible to construct solutions having the form of equations (17.10).

Taking exterior differentials of equations (17.10), we find that

$$d\omega^i = da^i \wedge dt + dt \wedge \frac{\partial \overline{\omega}^i}{\partial t} + \text{terms not depending on } dt. \tag{17.11}$$

In fact, by hypothesis, the form $\overline{\omega}^i$ can be written as

$$\overline{\omega}^i = M^i_k \, da^k.$$

Thus,

$$\begin{aligned} d\overline{\omega}^i &= \left(\frac{\partial M^i_k}{\partial t} \, dt \right) \wedge da^k = \frac{\partial M^i_k}{\partial t} \, dt \wedge da^k \\ &= dt \wedge \left(\frac{\partial M^i_k}{\partial t} \, da^k \right) = dt \wedge \frac{\partial \overline{\omega}^i}{\partial t}. \end{aligned}$$

For a solution of equations (17.6), the terms containing dt on the right-hand side of (17.6) are

$$c^i_{[jh]}\, dt \wedge (a^j\, \overline{\omega}^h - a^h\, \overline{\omega}^j) = c^i_{jh}\, a^j\, dt \wedge \overline{\omega}^h, \tag{17.12}$$

where on the right-hand side the summation is carried out with respect to the indices j and h separately.

Since t is the independent variable, the differential dt is also completely arbitrary. Thus if we substitute expressions (17.11) and (17.12) into equations (17.6), then the coefficients of dt on the left- and right-hand side of the equations obtained must coincide. The terms with dt are

$$da^i \wedge dt + dt \wedge \frac{\partial \overline{\omega}^i}{\partial t} = c^i_{jk}\, a^j\, dt \wedge \overline{\omega}^k.$$

It follows that

$$\frac{\partial \overline{\omega}^i}{\partial t} - da^i = c^i_{jk}\, a^j\, \overline{\omega}^k. \tag{17.13}$$

Thus, the forms $\overline{\omega}^i$, considered as functions of t, satisfy a system of ordinary differential equations with constant coefficients. Therefore, there exists a unique solution of this system satisfying the initial conditions

$$\overline{\omega}^i = 0 \text{ for } t = 0.$$

Therefore, if there exists a solution, we can actually compute it.

106. The system is satisfied by the solution constructed. Suppose now that a solution $\overline{\omega}^i$ is obtained. We insert it into equations (17.10) and prove that system (17.6) is identically satisfied. In other words, if we set

$$d\omega^i = c^i_{[jk]}\, \omega^j \wedge \omega^k + \Omega^i, \tag{17.14}$$

we must obtain

$$\Omega^i = 0.$$

In fact, we apply exterior differentiation to equations (17.14) and use the fact that the terms not containing Ω^i vanish by the imposed conditions which we assume are fulfilled. As a result, we obtain

$$d\Omega^i + c^i_{jk}\, \Omega^j \wedge \omega^k = 0. \tag{17.15}$$

Introduce the symbol d for differentiation with respect to the variable t and the symbol δ_α for differentiation with respect to the variable a^α.

We prove that

$$\Omega^i(d, \delta_\alpha) = 0, \quad \Omega^i(\delta_\alpha, \delta_\beta) = 0. \tag{17.16}$$

To say that

$$\Omega^i(d, \delta_\alpha) = 0$$

is the same as to say that the terms containing dt are the same on the left- and right-hand sides of equations (17.1). But comparison of these exact terms produced equations (17.3) whose integration gave the forms $\overline{\omega}^i$.

In order to justify the second equation of (17.16), we apply equations (17.14) to compute the bilinear form $\Omega^i(\delta_\alpha, \delta_\beta)$ for $t = 0$. We have

$$\begin{aligned}\Omega^i(\delta_\alpha, \delta_\beta) = \delta_\alpha \omega^i(\delta_\beta) - \delta_\beta \omega^i(\delta_\alpha)\\ -c^i_{[jk]}\left[\omega^j(\delta_\alpha)\,\omega^k(\delta_\beta) - \omega^j(\delta_\beta)\,\omega^k(\delta_\alpha)\right] = 0,\end{aligned}$$

since for $t = 0$,

$$\omega^i(\delta_\alpha) = \omega^i(\delta_\beta) = 0.$$

Now the trilinear covariant with the symbols of differentiation $d, \delta_\alpha, \delta_\beta$ associated with equations (17.15) can be written as

$$\begin{aligned}d\,\Omega^i(\delta_\alpha, \delta_\beta) \ &+\delta_\alpha\,\Omega^i(\delta_\beta, d) + \delta_\beta\,\Omega^i(d, \delta_\alpha) + c^i_{[jk]}\left[\Omega^j(d, \delta_\alpha)\,\omega^k(\delta_\beta)\right.\\ &\left.+\Omega^j(\delta_\alpha, \delta_\beta)\,\omega^k(d) + \Omega^j(\delta_\beta, d)\,\omega^k(\delta_\alpha)\right] = 0.\end{aligned}$$

Here, by the first (already proved) identity (17.16), all forms Ω^i for two symbols of differentiation d and δ vanish.

We obtain

$$d\,\Omega^i(\delta_\alpha, \delta_\beta) + c^i_{jk}\,\Omega^j(\delta_\alpha, \delta_\beta)\,\omega^k(d) = 0.$$

If we substitute here the values of $\omega^k(d)$ taken from (17.10) and set

$$H^i = \Omega^i(\delta_\alpha, \delta_\beta),$$

then our equations become a system of ordinary differential equations:

$$\frac{dH^i}{dt} + c^i_j k\, H^j\, a^k = 0.$$

This is a linear homogeneous system. Thus, it admits the solution

$$H^i = 0.$$

But since we proved that for $t = 0$,

$$\Omega^i(\delta_\alpha, \delta_\beta) = 0,$$

it follows that the above solution is the only possible solution for any t.

Thus, we have proved the second identity of (17.16). This immediately implies the vanishing of the exterior quadratic form Ω^i.

Now we need only to prove that all the forms ω^i we have found are linearly independent.

Note that the variables a^i and t occur only as the products a^it. In fact, equations (17.3), from which we found the forms $\overline{\omega}^i$, admit the substitution

$$t = k\,t', \;\; a^i = \frac{\alpha^i}{k}, \;\; k = \text{const.}$$

In order to integrate system (17.1), we integrate system (17.3) with the initial conditions

$$\overline{\omega}^i = 0 \;\text{ for }\; t = 0.$$

We get the forms ω^i if we substitute $t = 1$ in the obtained solution $\overline{\omega}^i$: since

$$\overline{\omega}^i = A^i_k\,du^k, \;\; \overline{\omega}^i = tA^i_k\,dv^k, \;\;\; u^k = v^k t,$$

we have

$$\overline{\omega}^i = \omega^i \;\text{ for }\; t = 1.$$

Thus, we can make vanish those of a^i from (17.9) that correspond to the forms ω^j_i with two indices.

In fact, from equations (17.10), we have

$$\omega^i = a^i\,dt + \overline{\omega}^i, \;\; \overline{\omega}^j_i = \omega^j_i.$$

1°. For example, if $K = 0$ (the Euclidean space), the system of equations (17.1) becomes

$$d\omega^i = \omega^k \wedge \omega^i_k, \;\; d\omega^j_i = \omega^k_i \wedge \omega^j_k, \tag{17.17}$$

and system (17.13) takes the form

$$\left\{\begin{aligned} &\frac{d\overline{\omega}^i}{dt} = da^i + a^k\,\overline{\omega}^i_k, \\ &\frac{d\overline{\omega}^j_i}{dt} = 0 \end{aligned}\right. \tag{17.18}$$

In fact, compare equations (17.17) with system (17.6),

$$d\omega^i = c^i_{[jk]}\,\omega^j \wedge \omega^k,$$

and set

$$\omega^j_i = \omega^\alpha, \quad \alpha = n+1, \dots, N.$$

Note that

a) The coefficients $c^i_{[jk]}$ are equal to either 0 or 1.

b) For $i \leq n$ (the case of the first of equations (17.17)), the index j also satisfies the inequality $j \leq n$, and the index k satisfies the inequality $k \geq n+1$.

c) For $i > n$ (the case of the second of equations (17.17)), both indices j and k satisfy the inequality $j, k > n$, but for such large j, all $a^j = 0$.

Integrating system (17.18), we find that

$$\overline{\omega}_i^j = 0, \quad \overline{\omega}^i = t\, da^i,$$

and as a result, we have

$$\omega^i = da^i, \quad ds^2 = \sum_i (da^i)^2.$$

(This proves one more time that the forms ω^i are linearly independent.)

2°. If $K \neq 0$, then by (17.1), we obtain

$$\begin{cases} \dfrac{d\overline{\omega}^i}{dt} = da^i + a^k\, \overline{\omega}_k^i, \\ \dfrac{d\overline{\omega}_i^j}{dt} = -K\,(a^i \overline{\omega}^j - a^j\, \overline{\omega}^i). \end{cases} \tag{17.19}$$

Multiplying the first equation of (17.19) by a_i and summing with respect to the index i, we find that

$$a_i\, \frac{d\overline{\omega}^i}{dt} = a_i\, da^i, \tag{17.20}$$

since

$$a_i\, a^k\, \overline{\omega}_k^i = \sum_{(i,k)} (a_i\, a^k\, \overline{\omega}_k^i + a_k\, a^i\, \overline{\omega}_i^k) = \sum_{(i,k)} a_i\, a_k\, (\overline{\omega}_k^i + \overline{\omega}_i^k) = 0.$$

Integrating equation (17.20) with respect to t and taking into account that a^i does not depend on t, for the initial conditions $\omega^i = 0$ for $t = 0$, we obtain

$$a_i \overline{\omega}^i = t\, a_i\, da^i. \tag{17.21}$$

Now, differentiating the first equation of (17.19) with respect to t, we get

$$\frac{d^2\overline{\omega}^i}{dt^2} = a^k\, \frac{d\overline{\omega}_k^i}{dt} = -K \sum_{(i,k)} a^k\, (a_k\, \overline{\omega}^i - a_i\, \overline{\omega}^k)$$

$$= -K\, a^k a_k\, \overline{\omega}^i + K\, a_i\, t\, a_k\, da^k.$$

The first transformation was made by means of the second equation of (17.19), and the second by equations (17.21).

Thus,

$$\frac{d^2\overline{\omega}^i}{dt^2} = -K\, a^k a_k\, \overline{\omega}^i + \varphi(t),$$

and we can integrate with the independent variable t and the unknown functions $\overline{\omega}^i$.

Chapter 18

Geometric Construction of a Space of Constant Curvature

107. Spaces of constant positive curvature. We can obtain a space of constant curvature by considering a hypersphere in an $(n+1)$-dimensional Euclidean space. We prove now that a hypersphere of radius R has the constant curvature $\frac{1}{R^2}$.

In an $(n+1)$-dimensional Euclidean space, consider a rectangular Cartesian coordinate system with an origin O and coordinates $x^1, \ldots, x^{n+1}$. The line element of this space is

$$ds^2 = (dx^1)^2 + (dx^2)^2 + \ldots + (dx^{n+1})^2.$$

The equation of the hypersphere with center at the origin and radius R is

$$(x^1)^2 + (x^2)^2 + \ldots + (x^{n+1})^2 = R^2.$$

To the fixed point O, we attach an orthonormal frame with unit basis vectors $\mathbf{I}_1, \ldots, \mathbf{I}_{n+1}$. Denote by M the common point of the hypersphere and the position vector of the direction $\mathbf{I}_{n+1}$. Then

$$\overrightarrow{OM} = R\mathbf{I}_{n+1}. \tag{18.1}$$

If the origin of our frame is fixed, the frame displacement is determined by the forms ω_α^β, $\alpha, \beta, \gamma = 1, \ldots, n+1$, satisfying the structure equations

$$d\omega_\alpha^\beta = \omega_\alpha^\gamma \wedge \omega_\gamma^\beta.$$

In what follows, the Greek letters take the values $\alpha, \beta, \gamma = 1, \ldots, n+1$, and the Latin letters take the values $i, j, k = 1, \ldots, n$. The equations of infinitesimal displacement of the point $\mathbf{M}$ are obtained by differentiation of equation (18.1):

$$d\mathbf{M} = R\, d\mathbf{I}_{n+1} = R\,(\omega_{n+1}^1 \mathbf{I}_1 + \ldots + \omega_{n+1}^n \mathbf{I}_n).$$

Thus the components of infinitesimal displacement of the point **M** are

$$\omega^i = R\omega^i_{n+1}, \tag{18.2}$$

from which it follows that

$$\omega^i_{n+1} = \frac{1}{R}\omega^i. \tag{18.3}$$

Exterior differentiation of equations (18.2) gives the following exterior quadratic equations:

$$\frac{d\omega^i}{R} = \omega^k_{n+1} \wedge \omega^i_k = \frac{1}{R}\omega^k \wedge \omega^i_k.$$

Thus,

$$d\omega^i = \omega^k \wedge \omega^i_k. \tag{18.4}$$

Similarly,

$$d\omega^j_i = \omega^k_i \wedge \omega^j_k + \omega^{n+1}_i \wedge \omega^j_{n+1},$$

so from (18.3) and $\omega^{n+1}_i = -\omega^i_{n+1}$, we have

$$d\omega^j_i = \omega^k_i \wedge \omega^j_k - \frac{1}{R^2}\omega^i \wedge \omega^j. \tag{18.5}$$

Hence, the curvature of the space is

$$K = \frac{1}{R^2}.$$

With the help of (18.1) and (18.2), we can easily find that

$$d\mathbf{M} = \omega^i \mathbf{I}_i. \tag{18.6}$$

Other equations of infinitesimal displacement are

$$d\mathbf{I}_\alpha = \omega^\beta_\alpha \mathbf{I}_\beta.$$

In addition, again using equations (18.1) and (18.2), we find that

$$d\mathbf{I}_i = \omega^k_i \mathbf{I}_k + \omega^{n+1}_i \mathbf{I}_{n+1} = \omega^k_i \mathbf{I}_k - \frac{\omega^i}{R^2}\overrightarrow{OM},$$

or

$$d\mathbf{I}_i = \omega^k_i \mathbf{I}_k - K\omega^i \overrightarrow{OM}. \tag{18.7}$$

We will call an *analytic point* a set of coordinates

$$x^1, x^2, \dots, x^{n+1}.$$

The *scalar square of this point* is

$$(x^1)^2 + (x^2)^2 + \dots (x^{n+1})^2 = \mathbf{M}^2 = \frac{1}{K}.$$

Thus, we have the following *scalar products*:

$$\mathbf{M}^2 = \frac{1}{K}, \quad (\mathbf{I}_i)^2 = 1, \quad \overrightarrow{OM} \cdot \mathbf{I}_i = 0, \quad \mathbf{I}_i \cdot \mathbf{I}_j = 0. \tag{18.8}$$

The differentials $d\mathbf{M}$ and $d\mathbf{I}_i$ allow us to find the differentials of any vector considered as a point having a certain scalar square: $\mathbf{X} = X^i\mathbf{I}_i$.

108. Mapping onto an n-dimensional projective space. In order to interpret the concept of negative curvature, it is convenient to consider $n+1$ numbers as homogeneous coordinates of a point of an elliptic space of dimension n. Here the points $(x^1, x^2, \dots, x^{n+1})$ and $(-x^1, -x^2, \dots, -x^{n+1})$ are considered identical.[1] Thus, an elliptic space composes only half of a spherical space.

Change the homogeneous coordinates in the space and suppose that

$$(x^1)^2 + (x^2)^2 + \dots (x^{n+1})^2 = F\left(x^{1'}, x^{2'}, \dots, x^{(n+1)'}\right)$$

and

$$ds^2 = F\left(dx^{1'}, dx^{2'}, \dots, dx^{(n+1)'}\right),$$

where F is a homogeneous second-degree polynomial (a form).

As a result, we obtain the definition of the space by means of the quadratic form F satisfying the condition

$$F\left(x^{1'}, x^{2'}, \dots, x^{(n+1)'}\right) = \frac{1}{K}. \tag{18.9}$$

We started from a definite form, but the form F could be also indefinite provided that ds^2 is positive. In this way we arrive at a hyperbolic ($K < 0$) space. We prove that this is possible only if the form F is a sum of n squares with positive signs and one square with negative sign.

A form F must be positive for all values dx related by the condition

$$\frac{\partial F}{\partial x^1} dx^1 + \dots + \frac{\partial F}{\partial x^{n+1}} dx^{n+1} = 0. \tag{18.10}$$

This equation is obtained by differentiation of equation (18.9) and shows that the point $(dx^1, \dots, dx^{n+1})$ lies in the polar hyperplane of the point $(x^1, \dots, x^{n+1})$ with respect to the absolute

$$F = 0. \tag{18.11}$$

If the polar hyperplane intersects the absolute, then the differential form

$$ds^2 = F\left(dx^1, dx^2, \dots, dx^{n+1}\right) \tag{18.12}$$

---

[1] For $n = 2$, the elliptic plane is obtained as the projection of a sphere from its center onto a tangent plane.

changes sign.

In a three-dimensional space, the last requirement excludes the ruled surfaces and admits only two cases:

1°. *The absolute is an imaginary quadric.* The form F is positive definite. The curvature K is positive. The space is elliptic.

2°. *The absolute is a real nonruled quadric*, for example, an ellipsoid. In order for the polar plane of a point to have no common points with the quadric, one must take a point (pole) inside the ellipsoid. The curvature K of the space is negative. The space is hyperbolic. Thus, a hyperbolic space is represented by interior points of the absolute. The form F decomposes into three squares with plus signs and one square with a minus sign.

109. Hyperbolic space. Let us show that for an n-dimensional hyperbolic space, we can choose the form F composed of n squares with plus signs and one square with a minus sign.

Consider a point $\mathbf{P}(0,\dots,0,1)$. In order for the coordinates of this point to satisfy equation (18.9), it is sufficient to take F of the form

$$F = \frac{(x^{n+1})^2}{K} + 2a_i x^i x^{n+1} + a_{ij} x^i x^j.$$

If we change the coordinate x^{n+1} by taking a new coordinate

$$x^{n+1} + K a_i x^i,$$

then the coordinates of the point $\mathbf{P}$ are not changed. Assuming that we made this coordinate transformation, we have

$$F = \frac{(x^{n+1})^2}{K} + \Phi(x^1,\dots,x^n).$$

At the point $\mathbf{P}$, linear equation (18.10) reduces to one term

$$dx^{n+1} = 0,$$

and line element (18.12) at the point $\mathbf{P}$ is positive if

$$\Phi(dx^1,\dots,dx^n) > 0.$$

Assuming that the form Φ is positive definite, we arrive at elliptic geometry if $K > 0$ and at hyperbolic geometry if $K < 0$.

Moreover, the points of the hyperbolic space are represented only by those points of the Euclidean space whose coordinates satisfy the inequality

$$F = \frac{(x^{n+1})^2}{K} + \Phi(x^1,\dots,x^n) < 0,$$

i.e., by the interior points of the absolute.

110. Representation of vectors in hyperbolic geometry. Let Q be a hyperquadric of the absolute, and let $\mathbf{M}(x^i)$ and $\mathbf{M}'(x^i + dx^i)$ be two internal neighboring points.

We can consider dx^i as coordinates of a point satisfying equation (18.10) which shows that the point (dx^i) is located in the polar hyperplane of the point $\mathbf{M}$ with respect to the absolute.

We have the same result for the velocity vector $\frac{d\mathbf{X}}{dt}$. The square of the length of the vector X^i is

$$F(x^1, x^2, \dots, x^{n+1}).$$

This is the scalar square of the point representing the vector. Thus, *any vector is represented by a point situated in the polar hyperplane of the initial point of the vector with respect to the absolute. The scalar square of this point is equal to the scalar square of the vector.*

The scalar product of two vectors with a common initial point is equal to the scalar product of the points representing these vectors.

Two vectors are orthogonal if the points representing them are conjugate, i.e., if the directions of these two vectors are conjugate with respect to the absolute.

The case $n = 2$. There are infinitely many straight lines through a point that are parallel to a given straight line, i.e., there are infinitely many straight lines that do not have common points inside the absolute. Two perpendiculars to a straight line are parallel, and so on.

In the elliptic interpretation, for the vector

$$\mathbf{X} = X^i \mathbf{I}_i,$$

we have

$$\begin{aligned} d\mathbf{X} &= dx^i\,\mathbf{I}_i + x^i\,d\mathbf{I}_i = dx^i\,\mathbf{I}_i + x^i\,(-K\,\omega^i\,\overrightarrow{OM} + \omega_i^k\,\mathbf{I}_k) \\ &= -K\,\omega_i\,X^i\,\overrightarrow{OM} + \mathbf{I}_i\,(dX^i + \omega_k^i X^k) = -K\,\omega_i\,X^i\,\overrightarrow{OM} + \mathbf{I}_i\,DX^i. \end{aligned}$$

It follows that

$$d\mathbf{X} = D\mathbf{X} - K\,\omega_i\,X^i\,\overrightarrow{OM}. \tag{18.13}$$

111. Geodesics in Riemannian manifold. The *acceleration* is the absolute derivative of the velocity vector with respect to time.

As usual, denote by ω^i the components of infinitesimal displacement of a moving point, by t the time, and by v^i the components of the velocity vector. We have

$$\omega^i = v^i\,dt.$$

It follows that the components g^i of the acceleration vector are

$$g^i = \frac{Dv^i}{dt} = \frac{dv^i}{dt} + v^k\,\frac{\omega_k^i}{dt}.$$

Setting

$$\omega_i^j = \gamma_i{}^j{}_k \omega^k,$$

we find that

$$g^i = \frac{dv^i}{dt} + \gamma_k{}^i{}_h v^k v^h.$$

For a geodesic, we have $g^i = 0$. It follows that the equations of geodesics are

$$\begin{cases} \dfrac{dv^i}{dt} + \gamma_k{}^i{}_h \, v^k v^h = 0, \\ \omega^i = v^i \, ds; \end{cases} \tag{18.14}$$

here we set $ds = dt$.

REMARK. Consider a holonomic system with n parameters $q^1, \dots, q^n$. The kinetic energy T is defined by the equation

$$T \, dt^2 = g_{ij} \, dq^i \, dq^j. \tag{18.15}$$

We assume that none of the constraints depend on time.

It is easy to see that instantaneous motions of the system (without exterior forces) are represented by geodesics of the space $q^1, \dots, q^n$.

Form (18.15) was considered by Volterra.[2] He calls v^i the characteristics of the motion.

A state of the system at a given moment is defined by the quantities $(q^i, \dot{q}^i)$, where $\dot{q}^i = \dfrac{dq^i}{dt}$. Volterra replaces $\dot{q}^i$ by linear combinations of v^i.

In particular, Volterra considers the case

$$\sum_i (v^i)^2.$$

This is our point of view.

Volterra poses the following problem: is it possible to choose v^i in such a way that $\gamma_k{}^i{}_h$ are constants (a system with independent characteristics)? If this is possible, then the first group and the second group of equations (18.14) can be integrated separately.

EXAMPLE: the Euler equations (the rotation of a rigid body). It would be interesting to study Riemannian manifolds with constant $\gamma_k{}^i{}_h$.

112. Pseudoequipollent vectors: pseudoparallelism. Is it possible to choose a rectangular frame at every point of a Riemannian manifold in such a way that

$$g^i = \frac{dv^i}{dt}\ ?$$

If this is possible, then for each geodesic, we have

$$v^i = \text{const}.$$

---

[2] Volterra, Atti Torino, 1887.

Thus, the components of the unit tangent vector are constant along a geodesic.

We call two vectors $\overrightarrow{MX}$ and $\overrightarrow{M'X'}$ *pseudoequipollent* if they have the same components with respect to the frames associated with them.

The unit vectors tangent to a geodesic are pseudoequipollent.

Suppose that two vectors tangent to two geodesics are pseudoequipollent at two points. Then they are also pseudoequipollent everywhere. We call such geodesics *pseudoparallel.*

This implies the following:

1°. *Each geodesic is pseudoparallel to itself.*

2°. *Two geodesics pseudoparallel to a third geodesic are pseudoparallel to one another.*

3°. *Through any point, there passes one and only one geodesic which is pseudoparallel to a given geodesic.*

4°. *If two geodesics intersect each other, then two other geodesics, that are pseudoparallel at their common point to the first two geodesics, intersect each other at the same angle.*

We show that the converse is also true: if it is possible to define a pseudoparallelism satisfying the following two (less strong) conditions:

1°). Through any point, there passes one and only one geodesic corresponding to a given geodesic,

2°). Two geodesics corresponding to two intersecting geodesics intersect each other at the same angle as the first pair,

then it is possible to find a frame giving $v^i = \text{const}$.

Proof. At the point O, take an orthonormal frame. To each direction emanating from a point M, associate the components a_1, a_2, a_3 of the unit vector tangent to the corresponding geodesic at the point O. The angle of two such directions (a) and (b) is defined by the formula

$$\cos\varphi = a_1 b_1 + a_2 b_2 + a_3 b_3.$$

Thus, there exists a certain rectangular frame at the point M such that if the direction cosines of the geodesic are a_1, a_2, and a_3, then the direction cosines of the corresponding geodesic at the point O are also a_1, a_2, and a_3.

Therefore, to any geodesic emanating from the point O, there corresponds also a geodesic emanating from the point M. The components of the velocity vector of a moving point along the geodesic are also constants. It follows that

$$\gamma^i_{kh} v^k v^h = 0.$$

In fact, at an arbitrary point M_0, we have

$$\frac{d\overset{\circ}{v}{}^i}{dt} = 0.$$

Using (18.14), the last equations can be written as

$$\overset{\circ}{\gamma}{}^{i}_{kh}\overset{\circ}{v}{}^{k}\overset{\circ}{v}{}^{h} = 0.$$

It follows that two geodesics are pseudoparallel if the same geodesic emanating from the point O corresponds to them.

In Euclidean space we have an ordinary parallelism. We will see that in elliptic space, there are two types of pseudoparallelism.

Consider a rigid body moving with an angular velocity (p, q, r) and the moments $A = B = C = 1$. For the axes connected with this rigid body, we have

$$\frac{dp}{dt} = \frac{dq}{dt} = \frac{dr}{dt} = 0, \quad T = p^2 + q^2 + r^2.$$

It follows that the parallelism is "absolute".

The equations remain the same for fixed axes in the space.

THE FRENET FORMULAS FOR GEODESICS.

If $\mathbf{T}$ is the unit tangent vector at a point M, then

$$\frac{d\mathbf{M}}{ds} = \mathbf{T}, \quad \frac{d\mathbf{T}}{ds} = \mathbf{0}, \tag{18.16}$$

113. Geodesics in spaces of constant curvature. From (18.13), we have

$$d\mathbf{X} = D\mathbf{X} - K\,X^i\omega_i\,\overrightarrow{OM},$$

$$X^i\omega_i = \mathbf{X}\cdot d\mathbf{M}.$$

For $\mathbf{X} = \mathbf{T}$, by (18.16) and $\mathbf{T}\cdot d\mathbf{M} = ds$, we find that

$$d\mathbf{T} = -K\,ds\,\overrightarrow{OM}.$$

This implies that

$$\frac{d\mathbf{T}}{ds} = -K\,\overrightarrow{OM}.$$

Set $\overrightarrow{OM} = \mathbf{M}$. Excluding $\mathbf{T}$ by means of the first equation of (18.16), we obtain

$$\frac{d^2\mathbf{M}}{ds^2} + K\,\mathbf{M} = \mathbf{0}. \tag{18.17}$$

Integrating this equation as a linear ordinary differential equation with constant coefficients, we obtain for $K > 0$

$$\mathbf{M} = \mathbf{A}\,\cos\left(s\sqrt{K}\right) + \mathbf{B}\,\sin\left(s\sqrt{K}\right),$$

where $\mathbf{A}$ and $\mathbf{B}$ are constant points.

The point $\mathbf{M}$ describes the straight line AB.

Thus, the geodesics of an elliptic space are ordinary straight lines.

If $\mathbf{M}_0$ is an initial point of a straight line and $\mathbf{T}_0$ is the point representing an initial direction, then we easily obtain

$$\mathbf{M} = \mathbf{M}_0 \cos\bigl(s\sqrt{K}\bigr) + \frac{\mathbf{T}_0}{\sqrt{K}} \sin\bigl(s\sqrt{K}\bigr). \tag{18.18}$$

The denominator in the second term of the right-hand side is explained by the fact that according to formulas (18.8), the point $\mathbf{M}$ as all analytic points has the norm $\frac{1}{\sqrt{K}}$ while $\mathbf{T}_0$ is the unit vector.

THE TOTAL LENGTH OF A STRAIGHT LINE

1°. *Spherical space*: $K = \frac{1}{R^2}$.

$$S_T = \frac{2\pi}{\sqrt{K}} = 2\pi R. \tag{18.19}$$

Since the trigonometric functions in equation (18.18) are of period 2π, the argument $s\sqrt{K}$ can vary from 0 to 2π. Thus, the arc length s can vary from 0 to $\frac{2\pi}{\sqrt{K}}$.

2°. *Elliptic space*:

$$S_T = \frac{\pi}{\sqrt{K}}. \tag{18.20}$$

In an elliptic space, the points with coordinates of opposite signs are identified. Since if the argument is increased by π, both trigonometric functions in equation (18.18) change their signs, the period for the point $\mathbf{M}$ is π for $s\sqrt{K}$ and $\frac{\pi}{\sqrt{K}}$ for s.

We can multiply both members of equation (18.18) by $\mathbf{M}_0$. Since

$$\mathbf{M}_0 \cdot \mathbf{T}_0 = 0, \ (\mathbf{M}_0)^2 = \frac{1}{\sqrt{K}},$$

we obtain

$$\mathbf{M}_0 \cdot \mathbf{M} = \frac{1}{K} \cos\bigl(s\sqrt{K}\bigr) = R^2 \cos\frac{s}{R}.$$

It follows that for a fixed point $\mathbf{M}_0$, the period for the point $\mathbf{M}$ is $\frac{\pi}{R}$.

3°. *Hyperbolic space*: $K = -\frac{1}{R^2} < 0$. Now when we integrate equations (18.17), we obtain hyperbolic functions instead of trigonometric ones:

$$\begin{aligned} \mathbf{M} &= \mathbf{M}_0 \cosh\bigl(s\sqrt{-K}\bigr) + \frac{\mathbf{T}_0}{\sqrt{-K}} \sinh\bigl(s\sqrt{-K}\bigr) \\ &= \mathbf{M}_0 \cosh\Bigl(\frac{s}{R}\Bigr) + \mathbf{T}_0\, R \sinh\Bigl(\frac{s}{R}\Bigr). \end{aligned} \tag{18.21}$$

If we change the normalization of the analytic point $\mathbf{M}_0$, we can write (18.21) in the form

$$\mathbf{M} = \mathbf{M}_0 + \mathbf{T}_0 \tanh\Big(\frac{s}{R}\Big). \tag{18.22}$$

When s changes from 0 to ∞, the point $\mathbf{M}$ changes from $\mathbf{M}_0$ to $\mathbf{M}_0 + \mathbf{T}_0 \tanh(\frac{s}{R})$. The last point lies on the absolute since

$$(\mathbf{M}_0 + \mathbf{T}_0 R)^2 = (\mathbf{M}_0)^2 + R^2 = 0.$$

Thus, the absolute is the locus of the points at infinity of straight lines. Each straight line has two points at infinity, $\mathbf{P}(\infty)$ and $\mathbf{Q}(-\infty)$. When the argument s changes sign, the hyperbolic tangent changes sign too, but in a hyperbolic space there is no identification of points with opposite signs of their coordinates.

114. The Cayley metric. Cayley defined the projective distance M_0 by means of the cross-ratio

$$(\mathbf{M}, \mathbf{M}_0; \mathbf{Q}, \mathbf{P}).$$

Since parameters of these four points are proportional to the numbers

$$\tanh\Big(\frac{s}{R}\Big), 0, -1, +1,$$

we have

$$(\mathbf{M}, \mathbf{M}_0; \mathbf{Q}, \mathbf{P}) = \frac{1 + \tanh\big(\frac{s}{R}\big)}{1 - \tanh\big(\frac{s}{R}\big)} = \frac{\sinh\big(\frac{s}{R}\big) + \cosh\big(\frac{s}{R}\big)}{-\sinh\big(\frac{s}{R}\big) + \cosh\big(\frac{s}{R}\big)} = e^{\frac{2s}{R}}.$$

It follows that

$$s = \frac{R}{2} \ln(\mathbf{M}, \mathbf{M}_0; \mathbf{Q}, \mathbf{P}).$$

REMARK. In Euclidean space, take the Euclidean sphere of radius R as the absolute.

As a parameter of a point $\mathbf{M}$, we can take the Euclidean length $r = |OM|$. It is easy to derive that

$$r = \tanh\Big(\frac{s}{R}\Big)$$

and

$$\overrightarrow{MM_0} = -\frac{1}{R^2} \sinh\Big(\frac{s}{R}\Big).$$

D. THE THEORY OF GEODESIC LINES

This page is intentionally left blank

Chapter 19

Variational Problems for Geodesics

115. The field of geodesics. We consider a family of lines close to an arc AB of a curve. Suppose that α is a parameter of the family and that $\alpha = 0$ for the curve AB.

On each line of the family, the points are defined by a parameter t. Take the unit vector tangent to an arc of a curve of the family as the coordinate vector $\mathbf{I}_1$. Choose the following symbols of differentiation:

$$d = \frac{\partial}{\partial t} \cdot dt, \quad \delta = \frac{\partial}{\partial \alpha} \cdot d\alpha,$$

$$\omega^i(d) = \omega^i, \quad \omega^i(\delta) = e^i.$$

By our choice of axis $\mathbf{I}_1$, we have

$$\omega^1 = ds, \quad \omega^2 = \ldots = \omega^n = 0.$$

From structure equations (17.1), it follows that

$$\begin{cases} d\omega^1 = \omega^i \wedge \omega_i^1, \\ d\omega^i = \omega^1 \wedge \omega_1^i + \omega^k \wedge \omega_k^i, \quad i, j, k = 2, \ldots, n, \\ d\omega_1^i = \omega_1^k \wedge \omega_k^i + R_{1i,1k}\, \omega^1 \wedge \omega^k + R_{1i,jk}\, \omega^j \wedge \omega^k, \end{cases}$$

and this implies the following bilinear decompositions

$$\begin{cases} \delta\omega^1 = de^1 + e^i \omega_i^1, \\ \delta\omega^i = de^i + e^1 \omega_1^i - e_1^i \omega^1 + e^k \omega_k^i, \\ \delta\omega_1^i = de_1^i + e_1^k \omega_k^i - e_k^i \omega_1^k - R_{1i,1k}\, e^k \omega^i. \end{cases} \tag{19.1}$$

116. Stationary state of the arc length of a geodesic in the family of lines joining two points. *We prove that the length of the arc AB in the family of lines passing through the points A and B is stationary only for a geodesic.*

Since now all lines of the family pass through the points A and B, the variation $\omega^i(\delta), i = 1, \dots, n$, at these points vanishes:

$$e^i = 0 \text{ at the points } A \text{ and } B. \tag{19.2}$$

Since the differential of the arc length of a curve of the family is equal to ω^i, the length of this curve between the points A and B is expressed by the integral

$$\lambda = \int_A^B \omega^1.$$

It follows that under the passage from one curve of the family to another and for fixed ends A and B, the variation of this line is

$$\delta\lambda = \int_A^B \delta\omega^1.$$

By means of equations (19.1), we can write this variation as

$$\delta\lambda = \int_A^B (de^1 + e^i\omega_i^1) = \int_A^B de^1 + \int_A^B e^i\omega_i^1 = \int_A^B (e^2\omega_2^1 + \dots + e^n\omega_n^1), \tag{19.3}$$

since the first integral $\int_A^B de^1$ reduces to the difference of the values of e^1 at the points A and B, and conditions (19.2) show that this difference is equal to zero.

In order to have $\delta\lambda = 0$ for any variations e^i, $i = 2, \dots, n$, vanishing at the points A and B, it is necessary and sufficient that

$$\omega_1^i = 0, \quad i = 2, \dots, n. \tag{19.4}$$

Equations (19.4) show that the arc AB in question is a geodesic. In fact, applying (15.24), we find that the absolute differential of the tangent $\mathbf{I}_1$ is

$$D\mathbf{I}_1 = \omega_1^i \mathbf{I}_i,$$

and under conditions (19.4), the tangent preserves its direction. Thus, we made our definition of a geodesic to be consistent with that of Riemann (see No. **61**).

REMARK. We see that it is always possible to choose frames at points of a geodesic in such a way that

$$\omega^i = 0, \ \omega_1^i = 0, \quad i = 2, \dots, n.$$

117. The first variation of the arc length of a geodesic. *Compute the variation of the arc length of the geodesic AB, when AB is transferred to $A'B'$.*

Now we wave the requirement that all lines of the family (α) pass through the points A and B common to all of them. Instead of this requirement, we request that all lines of the family (α) are geodesics. Then condition (19.4) is extended to all curves of the family (α).

Now the variation (19.3) of the arc length of a geodesic takes the form

$$\delta\lambda = \int_A^B (de^1 + e^i\omega_i^1) = \int_A^B de^1 = (e^1)_B - (e^1)_A.$$

Here $(e^1)_A$ is the projection of the displacement AA' onto the tangent at the point A of the arc AB, and $(e^1)_B$ is the projection of the displacement BB' onto the tangent at the point B of the arc AB (Fig. 7).

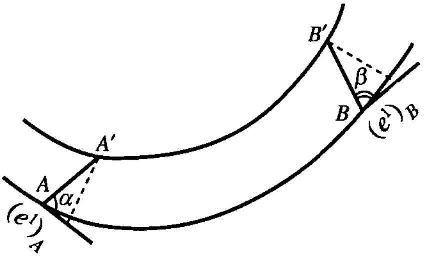

Fig. 7

Setting the angle between AA' and the tangent to AB at the point A equal to α and the angle between BB' and the tangent to AB at the point B equal to β,

$$\alpha = (\widehat{AA', AB}), \quad \beta = (\widehat{BB', AB}),$$

we obtain the desired variation of the arc length in the form

$$\delta\lambda = -AA'\cos\alpha - BB'\sin\beta.$$

COROLLARY. Consider a family of geodesics without common points. Suppose that their initial points A make up a line orthogonal to geodesics, and that all geodesics have the same length.

Then $\delta\lambda = 0$, since the length of a geodesic is not changed, and $\cos\alpha = 0$ because of orthogonality. Thus, $\cos\beta = 0$, and the trajectory BB' of the terminal point B is also orthogonal to the family of geodesics.

Thus, *if from the points of an arbitrary line AA', we draw geodesics orthogonal to the line AA' and plot the same segment on each geodesic, then the locus of these segments is also an orthogonal trajectory of the family of geodesics.*

As a result, we come to the notion of *parallel curves* AA' and BB'. The notion of *parallel surfaces* (of different dimensions) can be obtained in a similar way.

118. The second variation of the arc length of a geodesic. *Compute the second variation of the arc length of a geodesic for fixed points A and B.*

Consider a continuously differentiable family of lines (α) joining the points A and B and situated in a neighborhood of the geodesic $\alpha = 0$.

Now equation (19.3) takes the form

$$\delta\lambda = \int_A^B de^1 + \int_A^B e^i \omega_i^1. \tag{19.5}$$

We cannot assume that $\omega_1^i = 0$, since except for the line $\alpha = 0$, the lines of the family (α) are not geodesics. But for fixed ends A and B, we have

$$\omega^i(\delta) = e^i = 0 \ \text{ at the points } \ A \ \text{ and } \ B. \tag{19.6}$$

Therefore, the first integral on the right-hand side of (19.5) vanishes, and

$$\delta\lambda = \int_A^B e^i \omega_i^1.$$

For fixed ends A and B, we have

$$\delta^2\lambda = \int_A^B (\delta e^i \, \omega_i^1 + e^i \, \delta\omega_i^1).$$

But for the geodesic $\alpha = 0$, we have $\omega_i^1 = 0$, and

$$\delta^2\lambda = \int_A^B e^i \, \delta\omega_i^1. \tag{19.7}$$

Additional conditions. Suppose that at every point of the geodesic AB, a frame is obtained from an initial one at the point A by a *parallel transport.* This implies that along the geodesic AB, the forms ω_i^j vanish,

$$\omega_i^j = 0, \quad i, j = 1, \dots, n. \tag{19.8}$$

Thus, using the third equation of (19.1) and (19.8), we obtain

$$\delta\omega_1^i = de_1^i - R_{1i,1k} \, e^k \, \omega^1,$$

and as $\omega_i^1 = -\omega_1^i$, $\omega^1 = ds$, equation (19.7) takes the form

$$\delta^2\lambda = \int_A^B (-e_i \, de_1^i + R_{1i,1k} \, e^i \, e^k ds). \tag{19.9}$$

But by means of

$$\omega^1 = ds, \ \ \omega^2 = \ldots = \omega^n = 0, \ \ \delta\omega^i = 0,$$

and equations (19.8), the second equation of (19.1) gives

$$de^i = e^i_1 ds.$$

Now we can integrate by parts the first terms on the right-hand side of equation (19.9):

$$-\int_A^B e^i\, de^i_1 = -e^i e^i_1\Big|_A^B + \int_A^B (e^i_1)^2\, ds = \int_A^B (e^i_1)^2\, ds,$$

since $e_i = 0$ at the points A and B.

Hence, by equation (19.9), the second variation takes the form

$$\delta^2\lambda = \int_A^B \Big[\sum_i (e^i)^2 + R_{1i,1k}\, e^i\, e^k\Big]\, ds. \tag{19.10}$$

Consider now the Riemannian curvature in the planar direction defined by the geodesic AB and the vector $\overrightarrow{MM'}$, where M and M' correspond to the same value of t on two lines of the family. The matrix of components defining these directions is

$$\begin{pmatrix} 1 & 0 & 0 & \ldots & 0 \\ e^1 & e^2 & e^3 & \ldots & e^n \end{pmatrix},$$

and the Riemannian curvature (16.13) is

$$K = -\frac{R_{1i,1k}\, e^i\, e^k}{\sum_i (e^i)^2}, \quad i \neq 1. \tag{19.11}$$

Equations (19.10) and (19.11) imply that

$$\delta^2\lambda = \int_A^B \Big[\sum_i (e^i_1)^2 - K \sum_i (e^i)^2\Big]\, ds. \tag{19.12}$$

If the curvature is negative, $K < 0$, then $\delta^2\lambda > 0$, and the arc of the geodesic has its minimum (this conclusion is not rigorous). If $K > 0$ and the arc AB is not too long, then again $\delta^2\lambda > 0$.

119. The minimum for the arc length of a geodesic (Darboux's proof). Consider a hypersurface through the point A which is normal to the arc AB and a family of parallel hypersurfaces passing through the points of the arc AB.

If the arc AB is not too long, then through every point near the arc AB there passes one and only one of these hypersurfaces. In order to define a point P lying on a hypersurface of the family passing through a point M of the line AB, as coordinates we take the parameter

$$u = AM$$

and the parameters $v, w, \ldots$ of the hypersurface (M) with line element $d\sigma^2$. Then for the line passing through the point P and joining the points A and B, we obtain the line element

$$ds^2 = du^2 + d\sigma^2.$$

Thus, we have

$$\int_0^{u_1} \sqrt{du^2 + d\sigma^2} > \int_0^{u_1} du,$$

i.e.,

$$AP > AM,$$

and the geodesic $\alpha = 0$ is the shortest line.

120. Family of geodesics of equal length intersecting the same geodesic at a constant angle. *Suppose that we have a family of geodesics of the same length a emanating from the points of the geodesic AB and making with AB the same angle φ. Let us find the difference between the length of AB and the length of the line formed by the ends of geodesics of the family, if the segment a is infinitesimally small.*

For $\alpha = 0$, taking $\delta = \dfrac{\partial}{\partial \alpha}$ and $\delta a = 1$, we have

$$e^1 = \cos\varphi, \tag{19.13}$$

and for an appropriate choice of frame, we also have

$$e^2 = \sin\varphi, \quad e^3 = \ldots = e^n = 0. \tag{19.14}$$

(Obviously, the choice of frame here is different from that in No. **118**.) For displacements along geodesics of our family (for increasing α), the variation of the arc length of AB is determined by the formula (19.5),

$$\delta\lambda = \int_A^B de^1 + \int_A^B e^i \omega_i^1, \tag{19.15}$$

or

$$\delta\lambda = (e^1)_B - (e^1)_A + \int_A^B e^i \omega_i^1. \tag{19.16}$$

The second variation is

$$\delta^2\lambda = (\delta e^1)_B - (\delta e^1)_A + \int_A^B e^i\,\delta\omega_i^1.$$

Applying formulas (19.13) and (19.14) and taking into account that for an orthonormal frame, $\omega_1^1 = 0$, we find that

$$\delta^2\lambda = (\delta e^1)_B - (\delta e^1)_A + \int_A^B e^2\,\delta\omega_2^1.$$

For the geodesic $\alpha = 0$, by means of (19.4), the form ω_1^n vanishes. Thus, since $\delta\omega_2^1 = -\delta\omega_1^2$, from the third equation of (19.1), we have

$$\delta\omega_2^1 = -de_1^2 - e_1^k\omega_k^2 + R_{12,1i}\,e^i\,\omega^1.$$

Thus,

$$\delta^2\lambda = (\delta e^1)_B - (\delta e^1)_A - \sin\varphi \int_A^B (de_1^2 + e_1^k\omega_k^2 - R_{12,1i}\,e^i\,\omega^1). \tag{19.17}$$

But for $i = 2$, the second equation of (19.1) gives

$$0 = -e_1^2\,ds,$$

since on the line $\alpha = 0$, we have $\omega^2 = 0$, $e^2 = \sin\varphi = \text{const.}$, $\omega_1^i = 0$, $\omega_k^i = 0$, and for $i > 2$, it gives

$$0 = -e_1^i\,ds + a_2^i\,\sin\varphi\,ds,$$

since for $i > 2$, we have $\delta\omega^i = 0$, $e^i = 0$, $\omega_2^i = a_2^i\,ds$. It follows that

$$e_1^2 = 0, \quad e_1^i = a_2^i\,\sin\varphi, \quad i > 2.$$

Thus, the second variation (19.17) takes the form

$$\begin{aligned}\delta^2\lambda &= (\delta e^1)_B - (\delta e^1)_A + \sin\varphi \int_A^B \Big(\sum_i (a_2^i)^2\,\sin\varphi\,ds + R_{12,12}\,\sin\varphi\,ds\Big)\\ &= (\delta e^1)_B - (\delta e^1)_A + \sin^2\varphi \int_A^B \Big(\sum_i (a_2^i)^2 - K\Big)\,ds,\end{aligned}$$

where K is the Riemannian curvature in the planar direction (AB, AA').

For our construction of a frame,

$$De^i = \delta e^i + e^k e_k^i = 0,$$

and since the line AA' is a geodesic, then $e_k^1 = 0$ and

$$\delta e^1 = 0.$$

Hence,

$$\delta^2\lambda = \sin^2\varphi \int\limits_A^B \Big(\sum_i (a_2^i)^2 - K\Big)\, ds. \tag{19.18}$$

But

$$d\mathbf{I}_2 = \omega_2^i\, \mathbf{I}_i = a_2^i\, \mathbf{I}_i\, ds,$$

$$|d\mathbf{I}_2| = ds\sqrt{\sum_i (a_2^i)^2}.$$

Thus,

$$\sum_i (a_2^i)^2 = \frac{1}{h^2},$$

where h is a reduced pitch of a helical motion moving AA' to a neighboring location.

Therefore,

$$\delta^2\lambda = \sin^2\varphi \int\limits_A^B \Big(\frac{1}{h^2} - K\Big)\, ds \approx \Big(\frac{1}{h^2} - K\Big)\, l, \tag{19.19}$$

where

$$l = \int\limits_A^B ds = AB.$$

Now decomposing the length

$$A'B' = \lambda$$

into a series with respect to powers of the infinitesimal length a plotted on geodesics of our family, we obtain

$$\lambda = l + a\,\delta\lambda + \frac{1}{2}a^2\,\delta^2\lambda + \dots\ . \tag{19.20}$$

Since for the geodesic $\alpha = 0$ the first variation $\delta\lambda = 0$, we have

$$\lambda = l + \frac{1}{2}a^2\, l\, \sin^2\varphi\,\Big(\frac{1}{h^2} - K\Big) \tag{19.21}$$

and

$$\lambda^2 = l^2 + a^2\, l^2\, \sin^2\varphi\,\Big(\frac{1}{h^2} - K\Big).$$

If we denote by S the area of the "parallelogram" $ABB'A'$ (Fig. 8), from the last equation we find that

$$\frac{l^2 - \lambda^2}{S^2} = K - \frac{1}{h^2}. \tag{19.22}$$

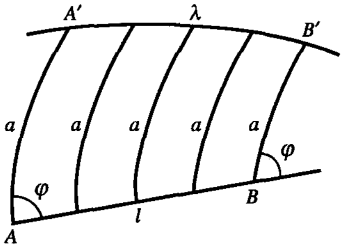

Fig. 8

1°. Suppose that $\frac{1}{h} = 0$. Then AA' and BB' are "parallel" in the sense of Levi-Civita. Levi-Civita called the "*parallelogramoid*" the figure obtained if one draws two "parallel" geodesics AA' and BB' of the same length through the ends A and B of the geodesic AB and join the points A' and B' by the arc $A'B'$ of another geodesic.

Our "parallelogram" is a similar figure for $h^{-1} = 0$. In this case,

$$K = \frac{l^2 - \lambda^2}{S^2}. \tag{19.23}$$

In Euclidean space, we have $l = \lambda$ while in elliptic space $\lambda < l$, and in hyperbolic space $\lambda > l$.

EXAMPLE. *Two-dimensional spherical space* $\left(n = 2,\ \varphi = \frac{\pi}{2}\right)$. We see that the arc of a small circle $A'B' < AB$. The quadrangle $ABB'A'$ is not a parallelogramoid.

We again obtain

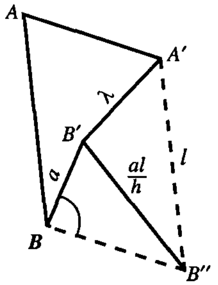
$$K = \frac{1}{R^2} \text{ (R is the radius of the sphere).}$$

2°. Suppose that $\frac{1}{h} \neq 0$. If $K < 0$, then the difference

$$\lambda - l = \frac{\frac{1}{h^2} - K}{\lambda + l} S^2$$

is greater than the corresponding difference in Euclidean space. It can decrease in elliptic space, but it is possible to choose h in such a way that

$\lambda = l$ and even $\lambda > l$ (Fig. 9).



A
A′
λ
B′
a
$\frac{al}{h}$
l
B
B″

Fig. 9

EXAMPLE. $n = 3$, $K = 0$, $\varphi = \frac{\pi}{2}$. We again find that

$$\lambda^2 = l^2 + \frac{a^2\,l^2}{h^2}.$$

Chapter 20

Distribution of Geodesics near a Given Geodesic

121. Distance between neighboring geodesics and curvature of a manifold. We return to the frame chosen in No. **118**. There we transported by parallelism a frame along a geodesic. Along a geodesic, we have

$$\omega_i^j = 0. \tag{20.1}$$

Now applying formulas (19.1), we obtain

$$\left\{\begin{aligned} &\delta\omega^1 = de^1, \\ &0 = de^i - e_1^i\, ds, \\ &0 = de_1^i - R_{1i,1k}\, e^k\, ds. \end{aligned}\right. \tag{20.2}$$

The above equations give us the rule which we should follow when we go off the geodesic AB in order to find an infinitesimally close geodesic.

Differentiating the second equation of (20.2) with respect to s and applying the third equation of (20.2) to eliminate $\frac{de_1^i}{ds}$, we find that

$$\frac{d^2e^i}{ds^2} - R_1{}^i{}_{1k}e^k = 0, \quad i = 2, \ldots, n, \tag{20.3}$$

where e^i remains arbitrary.

Setting

$$R_1{}^i{}_{1k} = -A_k^i, \tag{20.4}$$

we write

$$\frac{d^2e^i}{ds^2} + A_k^i\, e^k = 0. \tag{20.5}$$

The curvature in the planar direction defined by the geodesic and the arc (e^i) is

$$K = \frac{A_{ij}\, e^i\, e^j}{\sum\limits_i (e^i)^2}. \tag{20.6}$$

Take a parallelogramoid $ABB'A'$ (Fig.10). Set

$$AB = l, \;\; AA' = a.$$

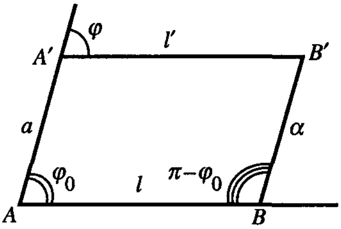


Fig. 10

We look for the upper base (a geodesic joining the points A' and B')

$$A'B' = l'.$$

Denote the angle at the point A by φ_0. Thus $\pi - \varphi_0$ is the angle at the point B.

Let λ be the length of the arc $A'B'$, the locus of points equidistant from the geodesic AB. Then from formula (19.23), we have

$$\frac{l^2 - \lambda^2}{S^2} = K. \tag{20.7}$$

The difference $\lambda - l'$ is negligible in our computations which only consider the terms up to $a^2 l$ (see (19.21)), since if α is the average distance between l and l', then $\lambda - l'$ is of order $\alpha^2\, l'$ or $\alpha^2\, l$, and α is of order $a\, l$. Thus, the difference $\lambda - l'$ is of order $a^2\, l^3$.

The computation of formula (20.7) is straightforward.

If we set $\delta = \dfrac{\partial}{\partial a}$, then from equation (19.15) we obtain

$$\begin{cases} \delta\lambda = (e^1)_B - (e^1)_A, \\ \delta^2\lambda = (\delta e^1)_B - (\delta e^1)_A. \end{cases} \tag{20.8}$$

But we have

$$\delta e^1 = e^i e^1_i,$$

and from (19.13) and (19.14), at the points A and B we have

$$e^1 = \cos\varphi_0, \quad e^2 = \sin\varphi_0, \quad e^3 = \ldots = e^n = 0. \tag{20.9}$$

Therefore, substituting these values into the second equation of (20.8), we obtain

$$\delta^2\lambda = (e_2 e_2')_B - (e_2 e_2')_A,$$

where by means of the second equation of (20.2),

$$e_i' = \frac{de^i}{ds} = e_1^i$$

and

$$\delta^2\lambda = \sin\varphi_0\,[(e_2')_B - (e_2')_A] = l\,\sin\varphi_0\,(e_2'')_C,$$

where C is an appropriately chosen point between A and B, and $e_2'' = \dfrac{d^2e}{ds^2}$.

For $\dfrac{1}{h} = 0$, by means of equation (19.19), we have

$$\delta^2\lambda = -K\,l\,\sin^2\varphi_0,$$

i.e., by means of (19.20),

$$l' = l - \frac{1}{2}\,K\,l\,\sin^2\varphi_0,$$

and we return to the formula

$$\frac{l^2 - \lambda^2}{S^2} = K.$$

122. The sum of the angles of a parallelogramoid. Denote the angle between the directions AA' and $A'B'$ by φ. From (20.9), at the point A, we have

$$-\sin\varphi_0\,\delta\varphi = \delta e^1 = \sin\varphi_0\,(e_2')_A.$$

Cancelling $\sin\varphi_0$, we obtain the equation

$$\delta\varphi = -(e_2')_A.$$

Integrating this equation under the condition $\delta a = 1$ (No. **120**), we find that

$$\varphi - \varphi_0 = -a(e_2')_A. \tag{20.10}$$

Since $AB = l$, at the point B, we have

$$e_2 = (e_2)_A + l\,(e_2')_A + \frac{1}{2}\,l^2\,(e_2')_A.$$

From this equation, using (19.14) and (20.9), we find that

$$\sin\varphi = \sin\varphi_0 + l\,(e_2')_A + \frac{1}{2}\,l^2\,(e_2')_A.$$

Since

$$\sin\varphi - \sin\varphi_0 = (\varphi - \varphi_0)\,\cos\varphi_1, \quad \varphi_1 = \varphi_0 + \theta\,(\varphi - \varphi_0), \quad 0 \le \theta \le 1,$$

we find that

$$-a\,\cos\varphi_1\,(e_2')_A = l\,(e_2')_A + \frac{1}{2}\,l^2\,(e_2')_A.$$

Assuming that $\frac{a}{l}$ tends to 0, we find from the last equation that

$$(e_2')_A = -\frac{1}{2}\,l\,(e_2')_A,$$

and hence by (20.3) and $R_1{}^2{}_{12} = -K$, we have[1]

$$(e_2')_A = \frac{1}{2}\,K\,l\sin\varphi_0. \tag{20.11}$$

Comparing equations (20.10) and (20.11), we find that

$$\varphi - \varphi_0 = -\frac{1}{2}\,K\,a\,l\sin\varphi_0,$$

i.e.,

$$\varphi = \varphi_0 - \frac{1}{2}\,K\,S,$$

where $S = a\,l\,\sin\varphi_0$ is the area of the parallelogramoid.

The sum of the interior angles A and A' is

$$\pi + \frac{1}{2}\,K\,S,$$

and the sum of the all angles of the parallelogramoid is

$$\pi + K\,S.$$

These are results of Saccheri.

123. Stability of a motion of a material system without external forces. *Suppose that a geodesic $A'B'$ is infinitesimally close at the point A' to a given geodesic AB. Are all the points of $A'B'$ also infinitesimally close to the points of AB?*

In this case, it is always possible to arrange that A_{ij} (see (20.4)) have the values

$$A_{ij} = 0, \quad i \neq j, \quad A_{ii} = K_i.$$

The basic equations

$$\frac{d^2e^i}{ds^2} + K_i\,e^i = 0 \quad (i \text{ not summed}) \tag{20.12}$$

---

[1] In the original, the sign "$-$" was erroneously written on the right-hand side of the formula (20.11). (*Translator's note.*)

are now differential equations with separable variables. If one of the components $K_i < 0$, then we have an instability. If all $K_i > 0$, then the motion is stable (Fig. 11).

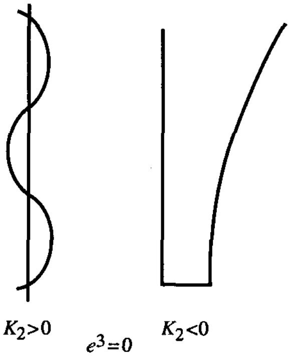

Fig. 11

Suppose that the dimension n of the manifold is three, $n = 3$. Develop a geodesic on the Euclidean space. The image is a plane curve in the preferred direction e^2 (or e^3). In other directions, the image is a space curve.

124. Investigation of the maximum and minimum for the length of a geodesic in the case A_{ij} = const. Suppose that for fixed points A and B, we have

$$\delta^2\lambda = \int_A^B \sum_i [(e_i')^2 - K_i\,(e_i)^2]\,ds.$$

Let us assume that the manifold is two-dimensional ($n = 2$) and of constant curvature. Then

$$\delta^2\lambda = \int_A^B [(e')^2 - K\,e^2]\,ds,$$

where e satisfies the equation

$$U'' + K\,U = 0; \quad U'' = \frac{d^2U}{ds^2}.$$

If the equation $U'' + K\,U = 0$ admits a nonvanishing solution between A and B, i.e., if there is a neighboring geodesic having no common points with AB, then

$\delta^2\lambda > 0$, and the minimum exists (provided that some additional conditions are satisfied). Suppose that $K > 0$. We can set

$$e = \eta U, \quad \eta = 0 \text{ at the points } A \text{ and } B.$$

Then

$$\delta^2\lambda = \int_A^B [U^2(\eta')^2 + 2UU'\eta\eta' + (U')^2\eta^2 - KU^2\eta^2]\,ds.$$

We have

$$\begin{aligned}\int_A^B 2UU'\eta\eta'\,ds &= \int_A^B UU'\,d(\eta)^2\,ds = [UU'\eta)^2]_A^B - \int_A^B \eta^2\,d(UU')\\ &= \int_A^B \eta^2\,[UU'' + (U')^2]\,ds\end{aligned}$$

and

$$\delta^2\lambda = \int_A^B [U^2(\eta')^2 - UU'\eta^2 - KU^2\eta^2]\,ds = \int_A^B U^2\,(\eta')^2\,ds > 0. \tag{20.13}$$

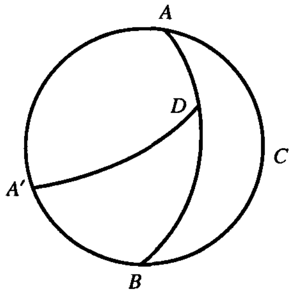

Fig. 12

This condition is satisfied if $K \leq 0$. If $K > 0$, then

$$U = a\,\sin(s - s_0)\,\sqrt{K}.$$

If the displacement of the length is less than $\dfrac{\pi}{\sqrt{K}}$, the condition $U \neq 0$ holds, and we have a minimum.

EXAMPLE OF A SPHERE. If $ACBA' > \pi$ (Fig. 12), there is no minimum for the length of a geodesic. In fact, consider a neighboring arc $ADB = ACB = \pi$, where D is an arbitrary point infinitesimally close to B. Take the arc of the great circle DA' through D. We have

$$AD + DA' < AD + DB + BA' < ACBA'.$$

It is always possible to eliminate the singular point D.

Return back to the general problem of arbitrary dimension n. A minimum is guaranteed if all $K_i \le 0$. Otherwise, we take $\widetilde{K}_i = \min K_i$. A minimum is guaranteed for a geodesic of length less than $\frac{\pi}{\sqrt{\widetilde{K}_i}}$.[2]

125. Symmetric vectors. Consider a point O of the Riemannian manifold. For a given point M, consider a geodesic OM and the arc $OM' = OM$ on the prolongation of this geodesic. The point M' is called *symmetric* to the point M with respect to the point O.

Consider a vector $\mathbf{V}$ emanating from the point M. This vector is the velocity of a moving point describing a certain line (C) for which a certain line (C') is symmetric with respect to the point O. The velocity $\mathbf{V}'$ $(V' = V)$ of a moving point describing the line (C') is the vector which is symmetric to the vector $\mathbf{V}$.

We transport by parallelism the vector $\mathbf{V}$ to a vector $\mathbf{V}_1$ with its initial point at M'.

Theorem 1. *The vector* $\mathbf{V}_1$ *is opposite to the vector* $\mathbf{V}'$ *to within second-order infinitesimals.*

Proof. We have a family of geodesics MOM' depending on the parameter α. Transport by parallelism the frames from O to every point M in such a way that

$$\omega_i^j = 0.$$

Then we have the Levi–Civita formulas (20.5),

$$\frac{d^2 e^i}{ds^2} + A_k^i\, e^k = 0.$$

For $s = 0$, all e^i vanish. Hence, all $e^{i'}$ also vanish for $s = 0$.

Set

$$e^{i'} = a^i.$$

Up to fourth-order infinitesimals, we have

$$e^i = a^i\, s - \frac{1}{6}\, s^3 A_k^i\, a^k.$$

Thus, at the point M,

$$e^i(+l) = a^i\, l - \frac{1}{6}\, l^3\, A_k^i\, a^k,$$

---

[2] Goursat, E., *Cours d'analyse; Tome 3: Intégrales infiniment voisines. Équations aux dérivées partielles du second ordre. Équations intégrales. Calcul des variations*, 3d edition, 1921. (JFM **48**, p. 491.)

and at the point M',

$$e^i(-l) = -a^i\,l + \frac{1}{6}\,l^3\,A^i_k\,a^k.$$

So, at the points M and M', e^i have the same absolute values but opposite signs.

Set also

$$a^i\,l = b^i.$$

Then

$$e^i(l) = b^i - \frac{1}{6}\,l^2\,A^i_k\,b^k,$$

$$e^i(-l) = -b^i + \frac{1}{6}\,l^2\,A^i_k\,b^k.$$

On the other hand,

$$e^1(l) = l' - l,$$

$$-e^1(-l) = l' - l,$$

where l' is the arc length of a geodesic close to OM. Therefore, by putting

$$e^1(l) = b^i,$$

we find that

$$e^1(-l) = -b^i$$

as desired.

For finite vectors $\mathbf{V}$ and $\mathbf{V}'$, all b^i are finite. This implies the theorem since the components of $\mathbf{V}'$ are the same as those of $\mathbf{V}$. ☐

126. Parallel transport by symmetry. Thus, in order to transport by parallelism a vector $\mathbf{V}$ from the point M to the point M', we construct at the point M' the vector $\mathbf{V}'$, which is symmetric to the vector $\mathbf{V}$, and take the vector $\mathbf{V}_1$ opposite to $\mathbf{V}'$. This construction is exact to within third-order infinitesimals.

The construction will be completely exact if the quantities e^i are odd functions, i.e., if the quantities A^i_k are even functions. This is the case, for example, if all A^i_k are constants (the case considered in No. **123** and No. **124**). The curvature in the direction of a plane element is preserved if one transports by parallelism this element tangentially to it. Then the symmetry preserves ds^2 (the symmetry is an *isometric transformation*).

This reduces to the fact that two moving points, that are constantly symmetric with respect to the point O, have the same velocity at all times. The latter is obvious from our previous discussion.

Conversely, suppose that the symmetry with respect to a point O is isometry. Then parallel transport preserves the curvature.

In fact, consider a bivector $(\mathbf{X}, \mathbf{Y})$ at a point M and transport by parallelism this bivector to a bivector $M'(\mathbf{X}', \mathbf{Y}')$. Let O be the midpoint of the geodesic MM', and the bivector $(\mathbf{X}_1, \mathbf{Y}_1)$ is symmetric to the bivector $(\mathbf{X}, \mathbf{Y})$. Since the symmetry is isometric, it preserves the curvature. Thus, the curvature of the area element $M'(\mathbf{X}_1, \mathbf{Y}_1)$ is equal to that of $M(\mathbf{X}, \mathbf{Y})$. But $(\mathbf{X}_1, \mathbf{Y}_1)$ coincides with $(\mathbf{X}', \mathbf{Y}')$ up to third-order infinitesimals.

Hence, the Riemannian curvature K is preserved up to third-order infinitesimals.

REMARK. *It is not necessary that a parallel transport is tangent to a plane element.*

PARTICULAR CASE: a space of constant curvature.

Corollary 2. *Take two points O and O' on the same geodesic and make consecutively two symmetries. Under such a transformation, the geodesic slides along itself. This transformation becomes isometry, if the symmetry possesses this property.*

127. Determination of three-dimensional manifolds, in which the parallel transport preserves the curvature. We put aside the case when the quadric-indicatrix Q of curvature is a sphere.

First, suppose that K_{11}, K_{22}, and K_{33} are mutually distinct. We prove that this case cannot take place. In fact, take at each point the trihedrons of principal directions. A principal direction remains principal under a parallel transport. Thus, the vector $\mathbf{I}_i$ is transported to the vector $\mathbf{I}'_i$, and as a result, $D\mathbf{I}_i = 0$. It follows that

$$\omega_i^j = 0.$$

Hence, the curvature vanishes, and this contradicts the hypothesis.

Only the case when Q is a surface of revolution remains to be considered. For example, we take

$$K_{11} = K_{22} = A, \quad K_{33} = C, \quad A \neq C.$$

We superpose the vector $\mathbf{I}_1$ with the axis of rotation of the indicatrix. The parallel transport moves the vector $\mathbf{I}_3$ to the vector $\mathbf{I}'_3$, but does not necessarily preserve $\mathbf{I}_1$ and $\mathbf{I}_2$.

We have only

$$D\mathbf{I}_3 = 0.$$

Therefore,

$$\omega_1^3 = 0, \quad \omega_2^3 = 0,$$

and also

$$A = \text{const.}, \quad C = \text{const.}$$

Conversely, suppose that the last four equations hold. Then the parallel transport preserves the curvature

$$A\,(\alpha^2 + \beta^2) + C\,\gamma^2,$$

since A, C, γ, and hence $\alpha^2 + \beta^2$, are preserved. So, we have the structure equations in the form

$$\begin{cases} d\omega^1 = \omega^2 \wedge \omega^1_2, \\ d\omega^2 = \omega^1 \wedge \omega^2_1, \\ d\omega^3 = 0, \\ d\omega^2_1 = -C\omega^1 \wedge \omega^2. \end{cases} \tag{20.14}$$

Moreover, we have

$$d\omega^3_1 = -A\omega^1 \wedge \omega^3.$$

Thus,

$$A = B = 0.$$

Do manifolds exist satisfying the system of equations (20.14)?

First of all, the third equation (20.14) implies

$$\omega^3 = dz.$$

Three other equations of (20.14) are the structure equations of a two-dimensional space of constant curvature $C \neq 0$.

Thus, all solutions are

$$ds^2 = dz^2 + d\sigma^2,$$

where $d\sigma^2 \neq 0$ is a line element of a two-dimensional space of constant curvature.

We can find all isometric transformations of this space. Such a transformation must preserve the basis vector $\mathbf{I}_3$, and hence also dz:

$$dz = dz'.$$

This implies that

$$z' = z + c,$$

where $c = \text{const}$.

In addition, there are two more families of isometric transformations $d\sigma^2$ (corresponding to the proper motions and the motions with symmetry).

Altogether, there are four families of transformations.

REMARK. There are important results for the manifolds of dimension higher than three. See these results in Chapter 11 "Symmetries and parallel transport. Symmetric spaces" of the book É. Cartan, *Les leçons sur la géométrie des espaces de Riemann*, Gauthier-Villars, Facs. 2, Paris, 1963. (MR **8**, 602; Zbl. **60**, 381.); English translation: É. Cartan, *Geometry of Riemannian spaces*, Math. Sci. Press, Brookline, MA, 1983; translated by James Glazebrook. (MR 85m:53001; Zbl. 603.53001.)

Chapter 21

Geodesic Surfaces

128. Geodesic surface at a point. Severi's method of parallel transport of a vector. If through a given point A in Riemannian manifold, we take the various geodesics (of the manifold) tangent at this point to the same plane element, we obtain a surface that is called *geodesic* at the point A. To see that a given surface is geodesic at one of its points, it suffices to consider the geodesics tangent to the surface at that point: they must lie entirely on the surface.

A geodesic surface at A has at this point vanishing principal curvatures, since the normal curvature is zero when passage is made from the point A to a point A' which is infinitesimally close to A on the surface. If we then transport by parallelism from A to A' a vector tangent to the surface at A, then it remains tangent to the surface at A' (up to infinitesimals of an order greater than the first).

It is possible to derive from this a geometric construction due to Severi[1] concerning parallel transport of a vector.

Theorem 1 (Severi). *To transport by equipollence a vector* $\mathbf{X}$ *emanating from a point* A *to a point* A'*, which is infinitesimally close to* A*, one must construct the joining geodesic* AA' *as well as the geodesic surface at* A *tangent to this geodesic and to the vector* $\mathbf{X}$ *at* A*. The required vector* $\mathbf{X}'$ *is tangent to this surface at* A' *and makes with the geodesic* AA'*, prolonged on the other side of* A'*, the same angle that the given vector* $\mathbf{X}$ *makes with the geodesic* AA'*.*

The last part of this theorem results from the fact that the direction of the geodesic AA' at the point A' is *parallel* to its direction at the point A and that parallel transport preserves the angle between two directions.

It is important to note that if we were to transport by parallelism the vector $\mathbf{X}$ along a *finite* arc of the geodesic AA' (sufficiently prolonged), the vector obtained would no longer be, in general, tangent to the considered geodesic surface, since there is no reason, *a priori*, to think that the surface, geodesic at A, is geodesic at the other points of the geodesic AA'.

---

[1] F. Severi, *Sulla curvature delle superficie a varietá*, Rend. Circ. matem. di Palermo, **42** (1917), pp. 227–229. (JFM **46**, p. 1068.)

If two surfaces, intersecting along a line (C), are geodesic at all points of (C), then they intersect at a constant angle, as the line (C) could be regarded as a curvature line on each of the surfaces.

In fact, if we develop the line (C) in Euclidean space (No. **67**), then at each point, this Euclidean space is tangent to both surfaces. The manifold of plane tangent elements of each of the surfaces forms a "curvature band" (in the sense of Blaschke). This means that after development, in a neighborhood of the developed line (C), the images of the tangent planes of both geodesic surfaces behave similarly to the tangent planes of two surfaces in Euclidean space, and the latter have a common curvature line as their intersection.

In particular, the Joachimstahl theorem on the intersection of two surfaces at a constant angle is preserved.

129. Totally geodesic surfaces. A surface which is geodesic at each of its points is called *totally geodesic.*[2] It enjoys the characteristic property that every geodesic which is tangent to this surface is completely contained within this surface.

Another characteristic property is that every geodesic that has two of its points (sufficiently close) on the surface is also completely contained within it. In fact, let A and A' be these two points. From the point A, there emanates an infinity of geodesics along the surface. They cover the whole surface within a sufficiently small neighborhood. Therefore, one of them passes through the point A', and since only one geodesic passes through two sufficiently close points in the manifold, it is precisely the geodesic in question. The converse can be proved in a similar way.

Thus, totally geodesic surfaces possess the characteristic properties of the *plane* in Euclidean space. We would reserve the name of *planes* for them. However, we will see that *the existence of such "planes" in a Riemannian manifold is an exceptional event.*

A totally geodesic surface enjoys the following three properties which are equivalent to one another:

First, *it has zero principal curvatures at each of its points.*

Second, *the unit vector normal to the surface remains normal under parallel transport along the surface.*

Third, *every vector tangent to the surface remains tangent under parallel transport along the surface.*

The second property is an immediate consequence of the first which in turn can be derived from the second. As for the second and the third, they are obviously equivalent to each other.

Let us show that the third property is *characteristic* of totally geodesic surfaces. This results in each of the first two properties being also characteristic of these surfaces.

Let us assume that every vector tangent to a given surface (S) remains tangent under parallel transport along (S), when its initial point describes an arbitrary curve on (S). This implies that the acceleration of a point describing an arbitrary curve on the surface (S) is always tangent to (S). If we express the coordinates of a point on the surface in terms of functions of two parameters α and β, it will suffice to have two second-order differential equations in α and β in order to show that the acceleration of the moving point is zero. *Therefore, there exists on the surface a geodesic* (of the manifold) *passing through an arbitrary point of this surface and having at this point an arbitrary direction tangent to the surface.* Consequently, the surface is totally geodesic. The proof by computation is not difficult.

---

[2] J. Hadamard, *Sur les éléments linéaires à plusieurs dimensions*, Darboux Bull. (2) **25** (1901), pp. 37–40. (JFM **32**, p. 614.)

130. Development of lines of a totally geodesic surface on a plane. Another important property of totally geodesic surfaces is the following: *If we develop in Euclidean space any one of the curves traced on a totally geodesic surface, a plane curve is obtained.*

In fact, since the absolute differential of the unit tangent vector is tangent to the surface, the principal normal is tangent to the surface. The unit vector of the binormal is then normal to the surface, and its absolute differential is zero. Thus, the torsion of the curve is zero. So, in the development, the curve with zero torsion becomes a plane curve.

The converse is also true. Suppose that for every curve on a surface, the torsion is zero, or what amounts to the same thing, that the velocity, the first and second order accelerations of a point moving along the surface in any manner are constantly coplanar. Suppose that the surface is defined by the equation $u^3 = 0$. It is always possible to imagine another point moving along the surface in such away that at any given instance, the quantities $\frac{du^i}{dt}$ and $\frac{d^2u^i}{dt^2}$ have the same numerical values as for the first moving point, whereas the quantities $\frac{d^3u^1}{dt^3}$ and $\frac{d^3u^i}{dt^3}$ vary from the first moving point to the second by arbitrary quantities α^1 and α^2, respectively. This implies that the arbitrary vector (α^1, α^2) tangent to the surface is coplanar with the velocity and acceleration of the first point. Consequently, this acceleration lies in the tangent plane to the surface, and all the lines on the surface are asymptotic. Thus, the surface is totally geodesic.

131. The Ricci theorem on orthogonal trajectories of totally geodesic surfaces. From this, we are going to deduce a remarkable theorem due to G. Ricci.[3]

Theorem 2. *If in a Riemannian manifold there exists a one-parameter family of planes, then their orthogonal trajectories establish an isometric point correspondence between the different planes of the family.*

Proof. In fact, let (P) be a plane in the family, and let (P') be an infinitesimally close plane. Let (C) be an arbitrary curve traced in the plane (P), and let (C') be the locus of the common points of (P') and the orthogonal trajectories taken through the different points of (C). Let us construct the representation in the Euclidean space of conjugacy (No. **67**) along the curve (C). In this representation, the curve (C) is *planar*, and the curve (C') is obtained from (C) by taking through each point of (C), an infinitesimal length normal to the plane of (C). Therefore, the first variation of any arc length of (C) is zero when going from (C) to (C'). On the other hand, since the length of (C') is preserved in this representation up to second-order infinitesimals, we see that in a Riemannian manifold, the first variation of the arc length of (C) is zero when going from the plane (P) to the infinitesimally close plane (P'). ☐

---

[3] G. Ricci, *Sulle superficie geodetiche in nun varietà qualunque e in particolare neue varietà a tre dimensioni.*, Rend. Acc. Lincei, **12** (1903), pp. 409–420. (JFM **34**, p. 658.)

An interesting consequence arises from this. In one of the planes (P_0) of the family, we take an arbitrary coordinate system u, v and denote by w a variable parameter defining the different planes of the family. Then, the line element of the manifold is of the form

$$ds^2 = d\sigma^2 + H(u, v, w)dw^2, \tag{21.1}$$

where $d\sigma^2$ is the line element of the plane (P_0):

$$ds^2 = E(u, v)du^2 + 2F(u, v)dudv + G(u, v)dv^2. \tag{21.2}$$

The line element (21.1) so obtained contains only one arbitrary function of three arguments (and functions of two arguments). It follows that Riemannian manifolds admitting a one-parameter family of planes are exceptional, since, as Riemann noticed, the most general line element ds^2 in three variables depends on three arbitrary functions of three variables (there are six arbitrary coefficients, but the possibility of arbitrary change in coordinates reduces the number of these functions to three).

Such a transformation must preserve the basis vector $\mathbf{I}_3$, and as a result, it must preserve dz:

$$dz = dz'.$$

This implies that

$$z' = z + c.$$

We have arrived at the conclusion of No. **127**.

4.2 Riemannian Curvature

Expression for Riemannian curvature: We are given two unit vectors p^i and q^i defined at a point P_0 of V_N. Consider the vector $t^i = p^i + q^i$; where and are parameters. This vector determines pencils of direction of p^i: Similarly, one and only one geodesic will pass through in the direction of q^i: These two geodesics through P_0 determine a two-dimensional geodesic surface through P_0 determined by the orientation of the unit vectors p^i and q^i. Call this surface by the name S.

The Gaussian curvature for the surface S at P_0 is called Riemannian curvature of V_N at P_0 determined by the orientation of p^i and q^i: Introduce Riemannian co-ordinates y^i with the origin at P_0: The equation of the surface S interms of y^i is

$$y^i = \quad p^i + \quad q^i \quad s; \tag{4.21}$$

where s denotes the arc length measured from P_0 to any point P along the geodesic Eq. (4.21) through P_0 in the direction of t^i: By taking $s = u^1$ and $s = u^2$, three parameters namely, ; and s can be reduced to two parameters u^1 and u^2: Here, u^1 and u^2 are taken as co-ordinates of any current point on the surface S defined by

$$y^i = u^1 p^i + u^2 q^i; \tag{4.22}$$

where p^i and q^i being fixed. Let $ds^2 = a_{ij}\, du^i du^j$; be the metric for the surface S. Let $\overset{k}{i\ j}\ {}_g$ and ${}_a$ be the Christoffel symbols of the second kind corresponding to the co-ordinates y^i and u^a, respectively, then

$$[\ ;\quad]_a = g_{km} \frac{\partial y^i}{\partial u} \frac{\partial y^j}{\partial u} \frac{\partial y^k}{\partial u} \quad \overset{m}{i\ j}\ {}_g \ : \tag{4.23}$$

Let R and R_{hijk} be the curvature tensors corresponding to the metrices $a \quad du \ du$ and $g_{ij}\, dy^i dy^j$, where ; ; ; take values 1 and 2; i and j take values from 1 to N. The number of independent components of $\overline{R}$ is $\frac{2^2(2^2 \quad 1)}{12} = 1$: We have,

$$\begin{aligned}
\overline{R}^0 &= \frac{\partial u}{\partial \bar u^1}\frac{\partial u}{\partial \bar u^2}\frac{\partial u}{\partial \bar u^1}\frac{\partial u}{\partial \bar u^2}\overline{R} = \frac{\partial u^1}{\partial \bar u^1}\frac{\partial u}{\partial \bar u^2}\frac{\partial u}{\partial \bar u^1}\frac{\partial u}{\partial \bar u^2}\overline{R}_1 + \frac{\partial u^2}{\partial \bar u^1}\frac{\partial u}{\partial \bar u^2}\frac{\partial u}{\partial \bar u^1}\frac{\partial u}{\partial \bar u^2}\overline{R}_2\\
&= \frac{\partial u^1}{\partial \bar u^1}\frac{\partial u^2}{\partial \bar u^2}\frac{\partial u}{\partial \bar u^1}\frac{\partial u}{\partial \bar u^2}\overline{R}_{12} + \frac{\partial u^2}{\partial \bar u^1}\frac{\partial u^1}{\partial \bar u^2}\frac{\partial u}{\partial \bar u^1}\frac{\partial u}{\partial \bar u^2}\overline{R}_{21}\\
&= \frac{\partial u^1}{\partial \bar u^1}\frac{\partial u^2}{\partial \bar u^2}\frac{\partial u^1}{\partial \bar u^1}\frac{\partial u^2}{\partial \bar u^2}\overline{R}_{1212} + \frac{\partial u^1}{\partial \bar u^1}\frac{\partial u^2}{\partial \bar u^2}\frac{\partial u^2}{\partial \bar u^1}\frac{\partial u^1}{\partial \bar u^2}\overline{R}_{1221}\\
&\quad + \frac{\partial u^2}{\partial \bar u^1}\frac{\partial u^1}{\partial \bar u^2}\frac{\partial u^1}{\partial \bar u^1}\frac{\partial u^2}{\partial \bar u^2}\overline{R}_{2121} + \frac{\partial u^2}{\partial \bar u^1}\frac{\partial u^1}{\partial \bar u^2}\frac{\partial u^2}{\partial \bar u^1}\frac{\partial u^1}{\partial \bar u^2}\overline{R}_{2121}
\end{aligned}$$

$$= \left[\left(\frac{\partial u^1}{\partial \bar u^1}\frac{\partial u^2}{\partial \bar u^2}\right)^2 \quad 2\frac{\partial u^1}{\partial \bar u^1}\frac{\partial u^2}{\partial \bar u^2}\frac{\partial u^2}{\partial \bar u^1}\frac{\partial u^1}{\partial \bar u^2} + \left(\frac{\partial u^2}{\partial \bar u^1}\frac{\partial u^1}{\partial \bar u^2}\right)^2 \right] \bar R_{1212}$$

$$= J^2 \bar R_{2121}; \text{ where } J = \begin{vmatrix} \frac{\partial u^1}{\partial \bar u^1} & \frac{\partial u^1}{\partial \bar u^2} \\ \frac{\partial u^2}{\partial \bar u^1} & \frac{\partial u^2}{\partial \bar u^2} \end{vmatrix} = \frac{\partial u}{\partial \bar u}: \tag{4.24}$$

Since a_{ij} is a covariant tensor, by Eq. (1.45), we get

$$\bar a \quad = \frac{\partial u}{\partial \bar u}\frac{\partial u}{\partial \bar u} a \quad \Rightarrow |\ \bar a \quad | = \left|\frac{\partial u}{\partial \bar u}\right| \left|\frac{\partial u}{\partial \bar u}\right| a \quad \Rightarrow \quad \bar a = J^2 a: \tag{4.25}$$

Dividing Eq. (4.24) by Eq. (4.25), we get

$$\frac{R'_{1212}}{\bar a} = \frac{R_{1212}}{\bar a} = \quad (\text{say}): \tag{4.26}$$

This , which is an invariant for transformation of co-ordinates, is defined as Gaussian curvature of the surface S at P_0: Hence, is the Riemannian curvature of S at P_0. Since Riemannian co-ordinate y^i with the origin at P_0 behave as geodesic co-ordinates with the pole at P_0: Thus, at P_0; ${k \atop i\ j}_g$ and $\quad_a = 0$: Therefore, we have

$$\bar R \quad = \frac{\partial}{\partial u}[\ ;\ ]_a + \frac{\partial}{\partial u}[\ ;\ ]_a \quad \text{at } P_0$$

or

$$\bar R_{1212} = \frac{\partial}{\partial \bar u^2}[21;1]_a + \frac{\partial}{\partial \bar u^1}[22;1]_a \text{ at } P_0: \tag{4.27}$$

or

$$= \frac{1}{a}\left(\frac{\partial}{\partial \bar u^2}[21;1]_a + \frac{\partial}{\partial \bar u^1}[22;1]_a\right); \text{ by Eq. } (4{:}26): \tag{4.28}$$

This is an expression for Riemannian curvature at P_0:

Formula for Riemannian curvature: Here, we have to derive a formula for Riemannian curvature interms of covariant curvature tensor of V_N. We know that

$$[\ ;\ ]_a = [ij;k]_g \frac{\partial y^i}{\partial u}\frac{\partial y^j}{\partial u}\frac{\partial y^k}{\partial u} + g_{ij}\frac{\partial^2 y^i}{\partial u u}\frac{\partial y^j}{\partial u}$$

$$= [ij;k]_g \frac{\partial y^i}{\partial u}\frac{\partial y^j}{\partial u}\frac{\partial y^k}{\partial u}; \text{ by Eq. } (4{:}22): \tag{4.29}$$

In particular, we have,

$$[21,1]_a = [ij,k]_g \frac{\partial y^i}{\partial u^2}\frac{\partial y^j}{\partial u^1}\frac{\partial y^k}{\partial u^1} = [ij,k]_g q^i p^j p^k$$

or

$$\frac{\partial}{\partial u^2}[21,1]_a = \frac{\partial}{\partial u^2}[ij,k]_g q^i p^j p^k = q^i p^j p^k q^h \frac{\partial}{\partial y^h}[ij,k]_g$$

$$= q^i p^j p^h q^k \frac{\partial}{\partial y^k}[ij,h]_g, \text{ interchanging } h \text{ and } k. \qquad (4.30)$$

By virtue of Eq. (4.29), we get

$$[22,1]_a = [ij,k]_g \frac{\partial y^i}{\partial u^2}\frac{\partial y^j}{\partial u^2}\frac{\partial y^k}{\partial u^1} = [ij,k]_g q^i q^j q^k$$

or

$$\frac{\partial}{\partial u^2}[22,1]_a = q^i q^j p^k p^h \frac{\partial}{\partial y^h}[ij,k]_g$$

$$= q^i q^k p^j p^h \frac{\partial}{\partial y^h}[ik,j]_g, \text{ interchanging } j \text{ and } k$$

$$= q^i q^k p^h p^j \frac{\partial}{\partial y^j}[ik,h]_g, \text{ interchanging } h \text{ and } j. \qquad (4.31)$$

Thus using Eqs. (4.30) and (4.31), from Eq. (4.27), the expression for $\overline{R}_{1212}$ at P_0 becomes

$$\overline{R}_{1212} = p^h q^i p^j q^k \left(-\frac{\partial}{\partial y^k}[ij,h]_g + \frac{\partial}{\partial y^j}[ik,h]_g\right) = p^h q^i p^j q^k R_{hijk}\,; \text{ at } P_0. \qquad (4.32)$$

Using the relation $a_{\alpha\beta} = g_{ij}\frac{\partial y^i}{\partial u^\alpha}\frac{\partial y^j}{\partial u^\beta}$, we get

$$a_{11} = g_{ij}\frac{\partial y^i}{\partial u^1}\frac{\partial y^j}{\partial u^1} = g_{ij}\,p^i p^j = g_{hj}\,p^h p^j.$$

$$a_{22} = g_{ij}\frac{\partial y^i}{\partial u^2}\frac{\partial y^j}{\partial u^2} = g_{ij}\,q^i q^j = g_{hk}\,q^i q^k.$$

$$a_{12} = g_{ij}\frac{\partial y^i}{\partial u^1}\frac{\partial y^j}{\partial u^2} = g_{ij}\,p^i p^j g_{hk}\,p^h q^k = a_{21}.$$

$$a = \begin{vmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{vmatrix} = p^h q^i p^j q^k\,[g_{hj}\,g_{ik} - g_{ij}\,g_{kh}]. \qquad (4.33)$$

Dividing Eq. (4.32) by Eq. (4.33), we get

$$= \frac{\overline{R}_{1212}}{a} = \frac{p^h q^i p^j q^k R_{hijk}}{p^h q^i p^j q^k [g_{hj}\, g_{ik} \quad g_{ij}\, g_{kh}]} = \frac{H_{hijk}\, R_{hijk}}{G_{hijk}\, H_{hijk}}; \tag{4.34}$$

where the N^4 functions H_{hijk} and G_{hijk} are given by

$$H_{hijk} = \begin{matrix} p^h & p^i \\ q^h & q^i \end{matrix} \quad \begin{matrix} p^j & p^k \\ q^j & q^k \end{matrix} \tag{4.35}$$

and

$$G_{hijk} = g_{hj}\, g_{ik} \quad g_{ij}\, g_{kh}: \tag{4.36}$$

Equation (4.34) is the required expression for Riemannian curvature of V_N at P_0 determined by the orientation of the unit vectors p^i and q^j at P_0: If the Riemannian curvature at P_0 does not change with the orientation of a 2-flat through P_0, then the co-ordinates of P_0 is called isotropic. Thus, if $N = 2$; Eq. (4.34) reduces to

$$= \frac{R_{1212}}{g_{11} g_{22} \quad g_{12}^2} = \frac{R_{1212}}{g}$$

shows that all points of a two-dimensional Riemannian space are isotropic. Thus, at a given point in Riemannian 2-space, the curvature is determined by the g_{ij} and their derivatives, and is independent of the directions of P and Q.

Theorem 4.2.1 If at each point, the Riemannian curvature of a space is independent of the orientation chosen, then it is constant throughout the space.

Proof: Let be the Riemannian curvature of V_N at P_0 determined by the orientation of the unit vectors p^i and q^j, then it is given by

$$= \frac{\overline{R}_{1212}}{a} = \frac{p^h q^i p^j q^k R_{hijk}}{p^h q^i p^j q^k [g_{hj}\, g_{ik} \quad g_{ij}\, g_{hk}]}:$$

If is independent of orientation determined by p^i and q^i, then

$$= \frac{R_{hijk}}{(g_{hj}\, g_{ik} \quad g_{ij}\, g_{hk})} \;) \quad R_{hijk} = (\quad g_{ij}\, g_{hk} + g_{hj}\, g_{ik}): \tag{4.37}$$

Here is constant throughout the space V_N. If $N = 2$, then at any point of V_2 there is only one orientation, which is same at every point and the theorem is obvious.

So, we consider the case of V_N; where $N \quad 3$: Since g_{ij} are constants with respect to the covariant differentiation, so covariant differentiation of Eq. (4.37) yields

$$R_{hijk;l} = (\quad g_{ij}\, g_{hk} + g_{hj}\, g_{ik})_{;l}: \tag{4.38}$$

where $_{;l}$ denotes the partial derivative of with respect to xs (as is scalar). Taking the sum of Eq. (4.38) and two similar equations obtained by cyclic permutation of the suffixes $j; k$ and l

$$(g_{ij}g_{hk} + g_{hj}g_{ik})_{;l} + (g_{ik}g_{hl} + g_{il}g_{hk})_{;j} + (g_{il}g_{hj} + g_{ij}g_{hl})_{;k}$$

$$= R_{hijk;l} + R_{hikl;j} + R_{hilj;k} = 0; \text{ by Eq. } (4{:}20): \qquad (4.39)$$

Since N 3 and therefore we can give three distinct values to the suffixes $j; k$ and l. Multiplying Eq. (4.39) by g^{hj} and using the fact that $g^{hj}g_{hl} = {}^{j}_{l}$, we get

$$({}^{h}_{i}g_{hk} + Ng_{ik})_{;l} + (g_{ik}\,{}^{j}_{l} + g_{il}\,{}^{j}_{k})_{;j} + (Ng_{il} + {}^{h}_{i}g_{hl})_{;k} = 0$$

or

$$(N \quad 1)g_{ik\ ;l} + (1 \quad N)g_{il\ ;k} = 0; \text{ as } {}^{i}_{j} = 0 \text{ for } i \neq j$$

or

$$g_{ik\ ;l} \quad g_{il\ ;k} = 0; \text{ as } N \neq 1$$

or

$$g^{ik}g_{ik\ ;l} \quad g^{ik}g_{il\ ;k} = 0; \text{ multiplying } g^{ik}$$

or

$$N_{;l} \quad {}_{;k} = 0; \text{ as } g^{ik}g_{ik} = N \text{ and } g^{ik}g_{il} = {}^{k}_{j}$$

or

$$(N \quad 1)_{;l} = 0\ ) \quad {}_{;l} = \frac{@}{@x^l} = 0; \text{ as } N \neq 1:$$

This implies that the partial derivatives of with respect to xs are all zero. Hence, is a constant at P_0. But P_0 be an arbitrary point of V_N. Hence, the Riemannian curvature is constant throughout the space V_N. This is known as Schurt's theorem.

EXAMPLE 4.2.1 Calculate for the Riemannian metric

$$ds^2 = (x^1)^{\ 2}(dx^1)^2 \quad (x^1)^{\ 2}(dx^2)^2:$$

Solution: For the given metric, we have $g_{11} = (x^1)^{\ 2}$; $g_{12} = 0 = g_{21}$; $g_{22} = \ (x^1)^{\ 2}$: Since $g = \ (x^1)^{\ 4}$; so the reciprocal tensors g^{ij} are given by

$$g^{11} = (x^1)^2; \quad g^{12} = 0 = g^{21}; \quad g^{22} = \ (x^1)^2:$$

The non-vanishing Christoffel symbols of second kind are

$$\genfrac{}{}{0pt}{}{1}{1\ 1} = \frac{1}{x^1} = \genfrac{}{}{0pt}{}{1}{2\ 2}; \quad \genfrac{}{}{0pt}{}{2}{1\ 2} = \genfrac{}{}{0pt}{}{2}{2\ 1} = \frac{1}{x^1}:$$

Using Eq. (4.6), the Riemannian curvature tensors R_{ijk} can be written as

$$R^1_{212} = \frac{\partial}{\partial x^2}\begin{Bmatrix}1\\2\;1\end{Bmatrix} + \frac{\partial}{\partial x^1}\begin{Bmatrix}1\\2\;2\end{Bmatrix} + \begin{Bmatrix}1\\ \;\;1\end{Bmatrix}\begin{Bmatrix} \\2\;2\end{Bmatrix} \quad \begin{Bmatrix}1\\ \;\;2\end{Bmatrix}\begin{Bmatrix} \\2\;1\end{Bmatrix}.$$

$$= \frac{\partial}{\partial x^1}\begin{Bmatrix}1\\2\;2\end{Bmatrix} + \begin{Bmatrix}1\\1\;1\end{Bmatrix}\begin{Bmatrix}1\\2\;2\end{Bmatrix} \quad \begin{Bmatrix}1\\2\;2\end{Bmatrix}\begin{Bmatrix}2\\2\;1\end{Bmatrix}.$$

$$= \frac{1}{(x^1)^2} \quad \frac{1}{x^1} \quad \frac{1}{x^1} \qquad \frac{1}{x^1} \quad \frac{1}{x^1} = \frac{1}{(x^1)^2}.$$

$$R^2_{212} = \frac{\partial}{\partial x^2}\begin{Bmatrix}2\\2\;1\end{Bmatrix} + \frac{\partial}{\partial x^1}\begin{Bmatrix}2\\2\;2\end{Bmatrix} + \begin{Bmatrix}2\\ \;\;1\end{Bmatrix}\begin{Bmatrix} \\2\;2\end{Bmatrix} \quad \begin{Bmatrix}2\\ \;\;2\end{Bmatrix}\begin{Bmatrix} \\2\;1\end{Bmatrix} = 0.$$

Using Eq. (4.13), the only non-vanishing covariant curvature tensor is given by

$$R_{1212} = g_{1\;}R_{212} = g_{11}R^1_{212} + g_{12}R^2_{212} = g_{11}R^1_{212}.$$

Thus, the Riemannian curvature κ given by Eq. (4.34) as

$$\kappa = \frac{R_{1212}}{g} = \frac{g_{11}R^1_{212}}{g_{11}g_{22}} = \frac{R^1_{212}}{g_{22}} = \quad 1.$$

EXAMPLE 4.2.2 Evaluate the Riemannian curvature at any point (x^i) of Riemannian 3 space in the directions $P = (1; 0; 0)$ and $Q = (0; 1; 1)$ if the metric is given by

$$g_{11} = 1; \quad g_{22} = 2x^1; \quad g_{33} = 2x^2; \quad g_{ij} = 0; \text{ for } i \neq j.$$

Hence, calculate R_{ij}; R^i_j and R.

Solution: Since $g = 4x^1x^2$; so the reciprocal tensors g^{ij} are given by

$$g^{11} = 1; \quad g^{22} = \frac{1}{2x^1}; \quad g^{33} = \frac{1}{2x^2}; \quad g^{ij} = 0 = g^{ji}; i \neq j.$$

The non-vanishing Christoffel symbols of second kind are

$$\begin{Bmatrix}1\\2\;2\end{Bmatrix} = \quad 1; \quad \begin{Bmatrix}2\\1\;2\end{Bmatrix} = \begin{Bmatrix}2\\2\;1\end{Bmatrix} = \frac{1}{2x^1};$$

$$\begin{Bmatrix}2\\3\;3\end{Bmatrix} = \quad \frac{1}{2x^1}; \quad \begin{Bmatrix}3\\2\;3\end{Bmatrix} = \begin{Bmatrix}3\\3\;2\end{Bmatrix} = \frac{1}{2x^2}.$$

Since $N = 3$; only six components of the Riemannian tensor need to be considered: R_{1212}; R_{1313}; R_{2323}; R_{1213}; R_{1232}; R_{1323}: Using Eq. (4.6), the Riemannian curvature tensors R_{ijk} can be written as

$$R^1_{212} = \frac{\partial}{\partial x^2}\ {}^{1}_{2\,1} + \frac{\partial}{\partial x^1}\ {}^{1}_{2\,2} + \ {}^{1}_{\ 1}\ \ {}_{2\,2}\ \ {}^{1}_{\ 2}\ \ {}_{2\,1}$$

$$= \frac{\partial}{\partial x^1}\ {}^{1}_{2\,2}\quad {}^{1}_{2\,2}\quad {}^{2}_{2\,1} = \frac{1}{2x^1}$$

and similarly, we get

$$R^1_{313} = 0\,;\ \ R^2_{323} = \frac{1}{4x^1x^2};\ \ R^1_{213} = 0\,;\ \ R^2_{123} = 0\,;\ \ R^3_{132} = \frac{1}{4x^1x^2}:$$

Using Eq. (4.13), three non-zero terms of covariant curvature tensor R_{ijkl} of rank 4 are given by

$$R_{1212} = g_{11}R^1_{212} = \frac{1}{2x^1};\ \ R_{2323} = g_{22}R^2_{323} = \frac{1}{2x^2}$$

and

$$R_{3132} = g_{33}R^3_{132} = \frac{1}{2x^1}:$$

Since $g = (g_{ij})$ is diagonal, all the non-zero G_{ijkl} will be derivable from the relation,

$$G_{ijij} = g_{ii}\, g_{jj}\ ;\ \ i < j \ \text{ and no summation:}$$

Thus, the non-vanishing G_{ijkl} are given by

$$G_{1212} = g_{11}g_{22} = 2\,x^1;\ \ G_{1313} = g_{11}g_{33} = 2\,x^2;\ \ G_{2323} = g_{22}g_{33} = 4\,x^1x^2:$$

For $\begin{matrix} P \\ Q \end{matrix} = \begin{matrix} 1 & 0 & 0 \\ 0 & 1 & 1 \end{matrix}$, the coefficients H_{hijk} are given by Eq. (4.35). Therefore,

$$H_{1212} = \begin{matrix} 1 & 0 \\ 0 & 1 \end{matrix}^{\,2} = 1;\qquad H_{2323} = \begin{matrix} 0 & 0 \\ 1 & 1 \end{matrix}^{\,2} = 0;$$

$$H_{3132} = \begin{matrix} 0 & 1 \\ 1 & 0 \end{matrix}\ \begin{matrix} 0 & 0 \\ 1 & 1 \end{matrix} = 0;\quad H_{1313} = \begin{matrix} 1 & 0 \\ 0 & 1 \end{matrix}^{\,2} = 1:$$

Thus, the Riemannian curvature given by Eq. (4.34) as

$$= \frac{R_{1212}H_{1212} + R_{2323}H_{2323} + R_{3132}H_{3132} + R_{1332}H_{1332}}{G_{1212}H_{1212} + G_{2323}H_{2323} + G_{3132}H_{3132} + G_{1332}H_{1332}}$$

$$= \frac{1{=}2x^1\quad 1 + \ \ 1{=}2x^2\quad 0 + 2\ \ 1{=}2x^1\quad 0}{(2x^1)\quad 1 + (2\,x^2)\quad 0 + 2\,(4x^1x^2)\quad 0} = \frac{1}{4x^1(x^1 + x^2)}:$$

Using formula (4.10), the Ricci tensors of first kind are given by

$$R_{ij} = R_{ij} = R^1_{ij\,1} + R^2_{ij\,2} + R^3_{ij\,3}$$
$$= g^{11}R_{1ij\,1} + g^{22}R_{2ij\,2} + g^{33}R_{3ij\,3}:$$

Therefore, the non-zero Ricci tensors are given by

$$R_{11} = g^{22}R_{2112} = \frac{1}{4(x^1)^2};\ R_{22} = g^{11}R_{1221} + g^{33}R_{3223} = \frac{1}{2x^1} \quad \frac{1}{4(x^1)^2}$$
$$R_{33} = g^{22}R_{2332} = \frac{1}{4x^1x^2};\ R_{12} = g^{33}R_{3123} = \frac{1}{4x^1x^2} = g^{33}R_{3213} = R_{21}:$$

Using formula (4.11), the Ricci tensors of first kind are given by

$$R^i_j = g^{i}\ R_{\ j} = g^{i1}R_{1j} + g^{i2}R_{2j} + g^{i3}R_{3j}:$$

So

$$R^1_1 = g^{11}R_{11} + g^{12}R_{21} + g^{13}R_{31} = \frac{1}{4(x^1)^2}:$$
$$R^2_2 = g^{12}R_{12} + g^{22}R_{22} + g^{23}R_{32} = \frac{1}{2x^1} \quad \frac{1}{2x^1} \quad \frac{1}{4(x^1)^2} \ :$$
$$R^3_3 = g^{31}R_{13} + g^{32}R_{23} + g^{33}R_{33} = \frac{1}{2x^2} \quad \frac{1}{4x^1x^2} \ :$$

Therefore, the total curvature R is given by Eq. (4.12) as

$$R = R^i_j = R^1_1 + R^2_2 + R^3_3$$
$$= \quad \frac{1}{4(x^1)^2} \quad \frac{1}{4(x^1)^2} \quad \frac{1}{8x^1(x^2)^2} \quad \frac{1}{8x^1(x^2)^2} = \frac{x^1 + 2(x^2)^2}{4(x^1x^2)^2}:$$

Deduction 4.2.1 Isotropic points: If the Riemannian curvature at x does not change with the orientation of a 2-flat through x, then x is called isotropic. All points of a two-dimensional Riemannian space are isotropic.

EXAMPLE 4.2.3 Find the isotropic points in the Riemannian space R^3 with metric

$$g_{11} = 1;\ g_{22} = (x^1)^2 + 1 = g_{33};\ g_{ij} = 0;\ \text{for } i \neq j$$

and calculate the Riemannian curvature at that points.

Solution: Since $g = [(x^1)^2 + 1]^2$; so the reciprocal tensors g^{ij} are given by

$$g^{11} = 1;\quad g^{ij} = 0 = g^{ji};\ g^{22} = \frac{1}{(x^1)^2 + 1} = g^{33}:$$

The non-vanishing Christoffel symbols of second kind are,

$$\left\{{1 \atop 2\;2}\right\} = x^1 = \left\{{1 \atop 3\;3}\right\};\quad \left\{{2 \atop 2\;1}\right\} = \frac{x^1}{(x^1)^2+1} = \left\{{3 \atop 3\;1}\right\}:$$

Using Eq. (4.6), the Riemannian curvature tensors R_{ijk} can be written as

$$\begin{aligned}
R^1_{212} &= \frac{\partial}{\partial x^2}\left\{{1 \atop 2\;1}\right\} + \frac{\partial}{\partial x^1}\left\{{1 \atop 2\;2}\right\} + \left\{{1 \atop \;\;1}\right\}\left\{{\atop 2\;2}\right\} \quad \left\{{1 \atop 2}\right\}\left\{{\atop 2\;1}\right\}\\
&= \frac{\partial}{\partial x^1}\left\{{1 \atop 2\;2}\right\} \quad \left\{{1 \atop 2\;2}\right\}\left\{{2 \atop 2\;1}\right\} = 1 \quad \frac{x^1}{(x^1)^2+1}(\;x^1) = \frac{1}{(x^1)^2+1}:\\
R^1_{313} &= \frac{\partial}{\partial x^3}\left\{{1 \atop 3\;1}\right\} + \frac{\partial}{\partial x^1}\left\{{1 \atop 3\;3}\right\} + \left\{{1 \atop \;\;1}\right\}\left\{{\atop 3\;3}\right\} \quad \left\{{1 \atop 3}\right\}\left\{{\atop 3\;1}\right\}\\
&= \frac{\partial}{\partial x^1}\left\{{1 \atop 3\;3}\right\} \quad \left\{{1 \atop 3\;3}\right\}\left\{{3 \atop 3\;1}\right\} = 1 \quad \frac{x^1}{(x^1)^2+1}(\;x^1) = \frac{1}{(x^1)^2+1}:\\
R^2_{323} &= \left\{{1 \atop 3\;3}\right\}\left\{{2 \atop 1\;2}\right\} = \frac{(x^1)^2}{(x^1)^2+1}:\\
R^1_{213} &= R^2_{123} = R^3_{132} = 0:
\end{aligned}$$

Using Eq. (4.13), the non-vanishing covariant curvature tensor R_{hijk} are given by

$$R_{1212} = g_{11}R^1_{212} = \left((x^1)^2+1\right)^{1} = R_{1313} = g_{11}R^1_{313};\, R_{2323} = g_{22}R^2_{323} = (x^1)^2:$$

Using Eq. (4.36), the non-vanishing tensors G_{hijk} are given by

$$G_{1212} = g_{11}g_{22} = (\,x^1)^2+1 = G_{1313} = g_{11}g_{33};\, G_{2323} = g_{22}g_{33} = \left((x^1)^2+1\right)^2:$$

If the curvature is to be independent of H_{hijk}, defined in Eq. (4.35) (which vary with the direction of the 2 flat), then $(\;x^1)^2 = 1$; i.e. $x^1 = \;1$: Therefore, the isotropic points compose two surfaces, on which the curvature has the value given by

$$\begin{aligned}
&= \frac{\left((x^1)^2+1\right)^{1}H_{1212} \quad \left((x^1)^2+1\right)^{1}H_{1313} \quad (x^1)^2H_{2323}}{[(x^1)^2+1]\,H_{1212}+[(\,x^1)^2+1]\,H_{1313}+[(\,x^1)^2+1]^2\,H_{2323}}\\
&= \left((x^1)^2+1\right)^{2}\frac{H_{1212}+H_{1313}+(\,x^1)^2\left((x^1)^2+1\right)H_{2323}}{H_{1212}+H_{1313}+[(\,x^1)^2+1]\,H_{2323}}\\
&= [1+1]^{2}\;1 = \frac{1}{4}:
\end{aligned}$$

EXAMPLE 4.2.4 Show that every point of R^3 is isotropic for the metric

$$ds^2 = (x^1)^{2}(dx^1)^2 + (x^1)^{2}(dx^2)^2 + (x^1)^{2}(dx^3)^2:$$

Solution: For the given metric, we have $g_{11} = (x^1)^{2} = g_{22} = g_{33}$; $g_{ij} = 0 = g_{ji}$; for $i \neq j$: Since $g = (x^1)^{6}$; so the reciprocal tensors g^{ij} are given by

$$g^{11} = (x^1)^2 = g^{22} = g^{33}; \quad g^{ij} = 0 = g^{ji}; \quad \text{for } i \neq j:$$

The non-vanishing Christoffel symbols of second kind are

$$\begin{matrix}1\\1\;1\end{matrix} = \frac{1}{x^1} = \begin{matrix}2\\1\;2\end{matrix} = \begin{matrix}3\\1\;3\end{matrix}; \quad \begin{matrix}1\\2\;2\end{matrix} = \frac{1}{x^1} = \begin{matrix}1\\3\;3\end{matrix}:$$

Using Eq. (4.6), the Riemannian curvature tensors R_{ijk} can be written as

$$R^1_{212} = \frac{\partial}{\partial x^2}\begin{matrix}1\\2\;1\end{matrix} + \frac{\partial}{\partial x^1}\begin{matrix}1\\2\;2\end{matrix} + \begin{matrix}1\\1\end{matrix}\begin{matrix}\\2\;2\end{matrix} \qquad \begin{matrix}1\\2\end{matrix}\begin{matrix}\\2\;1\end{matrix}:$$

$$= \frac{\partial}{\partial x^1}\begin{matrix}1\\2\;2\end{matrix} \quad \begin{matrix}1\\2\;2\end{matrix}\begin{matrix}1\\1\;1\end{matrix} \quad \begin{matrix}2\\2\;1\end{matrix}\begin{matrix}1\\2\;2\end{matrix} = \frac{1}{(x^1)^2}:$$

$$R^1_{313} = \frac{\partial}{\partial x^3}\begin{matrix}1\\3\;1\end{matrix} + \frac{\partial}{\partial x^1}\begin{matrix}1\\3\;3\end{matrix} + \begin{matrix}1\\1\end{matrix}\begin{matrix}\\3\;3\end{matrix} \qquad \begin{matrix}1\\3\end{matrix}\begin{matrix}\\3\;1\end{matrix}:$$

$$= \frac{\partial}{\partial x^1}\begin{matrix}1\\3\;3\end{matrix} + \begin{matrix}1\\3\;3\end{matrix}\begin{matrix}1\\1\;1\end{matrix} \quad \begin{matrix}3\\3\;1\end{matrix}\begin{matrix}1\\3\;3\end{matrix} = \frac{1}{(x^1)^2}:$$

$$R^2_{323} = \begin{matrix}1\\3\;3\end{matrix}\begin{matrix}2\\1\;2\end{matrix} = \frac{1}{(x^1)^2}; \quad R^1_{213} = R^2_{123} = R^3_{132} = 0:$$

Using Eq. (4.13), the non-vanishing covariant curvature tensors R_{hijk} are given by

$$R_{1212} = R_{1313} = R_{2323} = (x^1)^{4}; \quad G_{1212} = G_{1313} = G_{2323} = (x^1)^{4}:$$

The Riemannian curvature is given by

$$= \frac{R_{1212}H_{1212} + R_{1313}H_{1313} + R_{2323}H_{2323}}{G_{1212}H_{1212} + G_{1313}H_{1313} + G_{2323}H_{2323}}$$

$$= \frac{(x^1)^{4}}{[(x^1)^{4}]}\,\frac{H_{1212} + H_{1313} + H_{2323}}{H_{1212} + H_{1313} + H_{2323}} = 1:$$

Thus, we see that this Riemannian space is more than just isotropic; it is a space of constant curvature.

4.2.1 Space of Constant Curvature

If the Riemannian curvature is constant in a space V_N, then that space V_N is said to be of constant curvature.

Let us consider an Euclidean space S_N of N dimensions. We have to show that $R_{hijk} = 0$. In the case of S_N, the metric tensor g_{ij} is either 1 or 0. Hence,

$$[ij;k] = 0 = \begin{matrix} k \\ i\ j \end{matrix}. \tag{4.40}$$

Using Eq. (4.17), the covariant curvature tensors R_{hijk} are given by

$$R_{hijk} = \begin{matrix} \frac{\partial}{\partial x^j} & \frac{\partial}{\partial x^k} \\ [ij;h] & [ik;h] \end{matrix} + \begin{matrix} i\ j & i\ k \\ [hj;\ ] & [hk;\ ] \end{matrix} = 0, \quad \text{by Eq. (4.40).}$$

Conversely, let $R_{hijk} = 0$ in a space V_N, we have to show that the space V_N is an Euclidean space S_N. The Riemannian curvature at any point P of V_N is given by

$$= \frac{p^h q^i p^j q^k R_{hijk}}{p^h q^i p^j q^k [g_{hj} g_{ik} \quad g_{ij} g_{hk}]} = 0, \text{ as } R_{hijk} = 0.$$

Consequently, geodesics through P are straight lines. But P is an arbitrary point of V_N. Hence, geodesics through every point of V_N are straight lines. This will happen only if V_N is S_N. Therefore, a necessary and sufficient condition that a space V_N be an Euclidean space of N dimensions is that the curvature tensor vanishes.

4.2.2 Zero Curvature

A fundamental question has run unanswered through preceding sections: How can one tell whether a given metrisation of R^N is an Euclidean or not?

Let us consider a specified co-ordinate system (x^i) in which a Riemannian metric $g = (g_{ij})$. Now, consider a co-ordinate system in which $\bar{g}_{ij} = {}_{ij}$, which is a rectangular system. Suppose that a rectangular system $(\bar{x}^i)$ does exist. Then $e = 0$, since all Christoffel symbols vanish in $(\bar{x}^i)$. But the Riemannian curvature is an invariant, so that $= 0$ in the original co-ordinate (x^i) as well. Moreover,

$$g_{ij} u^i u^j = \bar{u}^i \bar{u}^j \quad 0.$$

Thus, we see that a Riemannian metric (g_{ij}) is the Euclidean metric if the Riemannian curvature is zero at all points and the metric is positive definite. To prove the converse portion, we set up a system of first order partial differential equations for N

rectangular co-ordinates $\bar{x}^i$ as functions of the given co-ordinates x^j $(j = 1, 2, \ldots, N)$. The system that immediately comes to mind is $G = J^T J$; or,

$$\frac{\partial \bar{x}^k}{\partial x^i}\frac{\partial \bar{x}^k}{\partial x^j} = g_{ij}\left(x^1, x^2, \ldots, x^N\right). \tag{4.41}$$

But the partial differential equation Eq. (4.41) is generally intractable because of its nonlinearity. Instead, we select the linear system that results when barred and unbarred co-ordinates are interchanged in Eq. (3.10) and then the $\overline{\left\{ {i \atop j\;k} \right\}}$ are

$$\frac{\partial^2 \bar{x}^k}{\partial x^i \partial x^j} = \left\{ {r \atop i\;j} \right\} \frac{\partial \bar{x}^k}{\partial x^r}. \tag{4.42}$$

Setting $\omega \equiv \bar{x}^k$ and $u_i \equiv \frac{\partial \bar{x}^k}{\partial x^i}$ yields the desired first order system

$$\frac{\partial \omega}{\partial x^i} = u_i \text{ and } \frac{\partial u_i}{\partial x^j} = \left\{ {r \atop i\;j} \right\} u_r. \tag{4.43}$$

A Riemannian metric $g = (g_{ij})$, specified in a co-ordinate system (x^i), is the Euclidean metric, if, under some permissible co-ordinate transformation Eq. (1.2), $\bar{g} = (\delta_{ij})$.

EXAMPLE 4.2.5 Show that R^3 under the following metric is Euclidean.

$$ds^2 = [(x^1)^2 + (x^2)^2](dx^1)^2 + [(x^1)^2 + (x^2)^2](dx^2)^2 + (dx^3)^2.$$

Solution: For the given metric, we have $g_{11} = (x^1)^2 + (x^2)^2 = g_{22}$, $g_{33} = 1$; $g_{ij} = 0 = g_{ji}$; $j \neq i$. Since g_{33} = constant, and g_{11} and g_{22} independent of x^3, so $\left\{ {i \atop j\;k} \right\} = 0$, whenever i, j or k equals to 3. Consequently, of the six independent components of the Riemannian tensor, R_{1212} is possibly non-zero. Since $g = [(x^1)^2 + (x^2)^2]^2$, so the reciprocal tensors g^{ij} are given by

$$g^{11} = \frac{1}{(x^1)^2 + (x^2)^2};\quad g^{22} = \frac{1}{(x^1)^2 + (x^2)^2};\quad g^{33} = 1.$$

The non-vanishing Christoffel symbols of second kind are

$$\left\{ {1 \atop 1\;1} \right\} = \frac{x^1}{(x^1)^2 + (x^2)^2} = \left\{ {2 \atop 1\;2} \right\};\quad \left\{ {1 \atop 2\;2} \right\} = -\frac{x^1}{(x^1)^2 + (x^2)^2}$$

$$\left\{ {1 \atop 1\;2} \right\} = \frac{x^2}{(x^1)^2 + (x^2)^2} = \left\{ {2 \atop 2\;2} \right\};\quad \left\{ {2 \atop 1\;1} \right\} = -\frac{x^2}{(x^1)^2 + (x^2)^2}.$$

Using Eq. (4.6), the Riemannian curvature tensors R_{ijk} can be written as

$$R^1_{212} = \frac{\partial}{\partial x^2}\ \substack{1\\2\ 1} + \frac{\partial}{\partial x^1}\ \substack{1\\2\ 2} + \substack{1\\1}\ \substack{\\2\ 2}\qquad \substack{1\\2}\ \substack{\\2\ 1}\ :$$

$$= \frac{\sqrt{g} + x^1(2x^1)}{g}\quad \frac{\sqrt{g}\quad x^2(2x^2)}{g} + \frac{x^1}{\sqrt{g}}\ \frac{x^1}{\sqrt{g}} + \frac{x^2}{\sqrt{g}}\ \frac{x^2}{\sqrt{g}}\quad \frac{x^2}{\sqrt{g}}\ \frac{x^2}{\sqrt{g}}\quad \frac{x^1}{\sqrt{g}}\ \frac{x^1}{\sqrt{g}}$$

$$= 0:$$

Consequently, $R_{1212} = 0 =$: As the metric is clearly positive definite, so the space is Euclidean.

EXAMPLE 4.2.6 Consider the two-dimensional metric $g_{11} = 0;\ g_{12} = 0 = g_{21};\ g_{22} = (x^2)^2$: Find the general solution in $(\bar{x}^i)$ co-ordinate system.

Solution: Since $g = (x^2)^2$; so the reciprocal tensors g^{ij} are given by

$$g^{11} = 1;\quad g^{12} = 0 = g^{21};\quad g^{22} = (x^2)^2:$$

The only non-vanishing Christoffel symbol of second kind is $\substack{2\\2\ 2} = \frac{1}{x^2}$; so the metric is obviously positive definite. Using Eq. (4.6), the Riemannian curvature tensors R_{ijk} can be written as

$$R^1_{212} = \frac{\partial}{\partial x^2}\ \substack{1\\2\ 1} + \frac{\partial}{\partial x^1}\ \substack{1\\2\ 2} + \substack{1\\1}\ \substack{\\2\ 2}\qquad \substack{1\\2}\ \substack{\\2\ 1} = 0:$$

$$R^2_{212} = \frac{\partial}{\partial x^2}\ \substack{2\\2\ 1} + \frac{\partial}{\partial x^1}\ \substack{2\\2\ 2} + \substack{2\\1}\ \substack{\\2\ 2}\qquad \substack{2\\2}\ \substack{\\2\ 1} = 0:$$

Using Eq. (4.13), the covariant curvature tensor is given by

$$R_{1212} = g_1\ R_{212} = g_{11}R^1_{212} + g_{12}R^2_{212} = 0:$$

Thus, the Riemannian curvature is $= \frac{R_{1212}}{g} = 0$: Let us introduce,

$$f_1 = \frac{\partial \bar{x}^1}{\partial x^1};\ f_2 = \frac{\partial \bar{x}^1}{\partial x^2};\ f_3 = \frac{\partial \bar{x}^2}{\partial x^1};\ f_4 = \frac{\partial \bar{x}^2}{\partial x^2};$$

then the system of Eq. (4.41) becomes,

$$f_1^2 + f_3^2 = 1;\quad f_1 f_2 + f_3 f_4 = 0;\quad f_2^2 + f_4^2 = (x^2)^2$$

$$\Rightarrow\quad f_1 = f_1;\quad f_2 = x^2\sqrt{1\quad f_1^2};\quad f_3 = \sqrt{1\quad f_1^2};\quad f_4 = x^2 f_1:$$

Therefore, the system of equations becomes two simple first order systems in $\bar{x}^1$ alone and $\bar{x}^2$ alone

$$\mathrm{I}: \ \frac{\partial \bar{x}^1}{\partial x^1} = f_1, \qquad \frac{\partial \bar{x}^1}{\partial x^2} = x^2\sqrt{1 \quad f_1^2}$$

$$\mathrm{II}: \ \frac{\partial \bar{x}^2}{\partial x^1} = \quad \sqrt{1 \quad f_1^2}, \qquad \frac{\partial \bar{x}^2}{\partial x^2} = x^2 f_1.$$

The unknown function f_1 is determined by the requirements that the two conditions I and II be compatible

$$\frac{\partial f_1}{\partial x^2} = \frac{\partial}{\partial x^1} \quad x^2\sqrt{1 \quad f_1^2} \quad \text{and} \quad \frac{\partial}{\partial x^2} \quad \sqrt{1 \quad f_1^2} \quad = \frac{\partial}{\partial x^1} \quad x^2 f_1 \quad .$$

The only function satisfying these two compatibility condition is

$$f_1 = \text{ constant } = \cos$$

and I and II immediately integrate to give

$$\bar{x}^1 = x^1\cos \quad + \frac{1}{2}(x^2)^2\sin \quad + c$$

$$\bar{x}^2 = \quad x^1\sin \quad + \frac{1}{2}(x^2)^2\cos \quad + d,$$

where c and d are constants and we use, of course, free to set $= c = d = 0$. From Eq. (4.43) we have to solve,

$$\frac{\partial \omega}{\partial x^1} = u_1, \quad \frac{\partial \omega}{\partial x^2} = u_2$$

$$\frac{\partial u_1}{\partial x^1} = 0, \ \frac{\partial u_1}{\partial x^2} = 0, \quad \frac{\partial u_2}{\partial x^1} = 0, \ \frac{\partial u_2}{\partial x^2} = u_2 \quad {}^{2}_{2\,2} \quad = \frac{u_2}{x^2}.$$

$$\omega = a_1x^1 + a_2(x^2)^2 + a_3, \quad a_1, a_2, a_3 = \text{ constant}$$

$$\bar{x}^k = a^k_1x^1 + a^k_2(x^2)^2 + a^k_3, \quad a^k_1 = \text{ constant},$$

which is similar to the solution set $\bar{x}^1$ and $\bar{x}^2$ as above.

Deduction 4.2.2 The quasilinear first-order system,

$$\frac{\partial u}{\partial x^j} = F_j\,(u_0, u_1, \ldots, u_m;\ x^1, x^2, \ldots, x^n), \qquad = 0, 1, \ldots, m; j = 1, 2, \ldots, n$$

where the functions F_j are of the differentiability class C^1; has a nontrivial solution for the u , bounded over some region of R^n, if and only if

$$\frac{\partial F_j}{\partial u}F_k + \frac{\partial F_j}{\partial x^k} = \frac{\partial F_k}{\partial u}F_j + \frac{\partial F_k}{\partial x^j}, \qquad = 0, 1, \ldots, m; \quad 1 \quad j < k \quad n;$$

where summations run from 0 to m. The conditions $R_{hijk} = 0$ are the sufficient condition for compatibility.

4.2.3 Einstein Tensor

The covariant tensor

$$_{ij} = R_{ij} \quad \frac{1}{2} R g_{ij} \qquad (4.44)$$

is called Einstein tensor. The mixed tensor

$$^{i}_{j} = R^{i}_{j} \quad \frac{1}{2}\,^{i}_{j} R; \quad g^{i} \; R_{j} = R^{i}_{j} \text{ and } g^{ij} R_{ij} = R \qquad (4.45)$$

is called the Einstein tensor. This tensor is widely used in the general theory of relativity.

EXAMPLE 4.2.7 Prove that for any Riemannian metric, the divergence of the Einstein tensor is zero at all points.

Solution: The Einstein tensor $^{i}_{j}$ is given by

$$^{i}_{j} = R^{i}_{j} \quad \frac{1}{2} \quad ^{i}_{j} \; R;$$

where $g^{i} \; R_{j} = R^{i}_{j}$ and $g^{ij} R_{ij} = R$: Covariant differentiation of the Einstein tensor $^{i}_{j}$ with respect to x^{k} is

$$\begin{aligned} ^{i}_{j;k} &= R^{i}_{j;k} \quad \frac{1}{2}\,^{i}_{j;k} R \quad \frac{1}{2}\,^{i}_{j} R_{;k} \\ &= R^{i}_{j;k} \quad \frac{1}{2}\,^{i}_{j} R_{;k}; \text{ as } ^{i}_{j;k} = 0: \end{aligned}$$

Hence, the divergence of the Einstein tensor $^{i}_{j}$ is given by

$$\begin{aligned} ^{i}_{j;i} &= R^{i}_{j;i} \quad \frac{1}{2}\,^{i}_{j} R_{;i} \\ &= R^{i}_{j;i} \quad \frac{1}{2} R_{;j} = \frac{1}{2} R_{;j} \quad \frac{1}{2} R_{;j} = 0: \end{aligned}$$

Thus, Einstein tensor is divergence free. This equation plays an important role in the theory of relativity.

4.2.4 Flat Riemannian Spaces

We know, covariant differentiation of all vectors is commutative if and only if the Riemann{Christoffel curvature tensor R_{ijk} is identically zero. The covariant curvature tensors of fourth order R_{hijk} are zero, then all the components of the tensor R_{hijk} are zero and vice versa. A Riemannian space whose curvature tensor is identically zero is called a flat space.

If in a neighbourhood N of a point O of V_N, there exists a co-ordinate system with respect to which the metric tensor has constant values, then V_N is said to be locally flat at O. The Riemannian space V_N is said to be locally flat, if the metric tensor g_{ij} has constant values throughout V_N.

A space is Euclidean (or flat) if it is possible to find a Cartesian co-ordinate system everywhere in it; if this is not possible, the space is non-Euclidean (or curved).

Theorem 4.2.2 The necessary and sufficient condition that a space V_N be locally flat (or flat) in the neighbourhood of O is that the curvature tensor be identically zero.

Proof: First let V_N be locally flat in the neighbourhood of O, so that g_{ij} = constant for all i and j. Thus,

$$\frac{\partial g_{ij}}{\partial x^k} = 0 \Rightarrow \left\{ {k \atop i\;j} \right\} = 0;$$

in the neighbourhood of O. The Riemann–Christoffel symbol R^{α}_{ijk} is given by

$$\begin{aligned} R^{\alpha}_{ijk} &= -\frac{\partial}{\partial x^k}\left\{ {\alpha \atop i\;j} \right\} + \frac{\partial}{\partial x^j}\left\{ {\alpha \atop i\;k} \right\} - \left\{ {\beta \atop i\;j} \right\}\left\{ {\alpha \atop \beta\;k} \right\} + \left\{ {\beta \atop i\;k} \right\}\left\{ {\alpha \atop \beta\;j} \right\} \\ &= 0; \text{ in the neighbourhood of } O. \end{aligned}$$

Conversely, let $R^{\alpha}_{ijk} = 0$ in the neighbourhood of O. To prove that V_N is locally flat, it is enough to prove that g_{ij} = constant in the neighbourhood of O. Given co-ordinate system x^i, let us choose co-ordinate system $\bar{x}^i$ such that

$$\left\{ {\alpha \atop \beta\;\gamma} \right\} = \frac{\partial^2 \bar{x}^l}{\partial x^\beta \partial x^\gamma}\frac{\partial x^\alpha}{\partial \bar{x}^l}. \tag{4.46}$$

The tensor law of transformation for the Christoffel symbol is

$$\overline{\left\{ {k \atop i\;j} \right\}} = \left\{ {\gamma \atop \alpha\;\beta} \right\}\frac{\partial x^\alpha}{\partial \bar{x}^i}\frac{\partial x^\beta}{\partial \bar{x}^j}\frac{\partial \bar{x}^k}{\partial x^\gamma} + \frac{\partial^2 x^l}{\partial \bar{x}^i \partial \bar{x}^j}\frac{\partial \bar{x}^k}{\partial x^l}$$

or

$$\left\{ {k \atop i\;j} \right\} = \overline{\left\{ {\gamma \atop \alpha\;\beta} \right\}}\frac{\partial \bar{x}^\alpha}{\partial x^i}\frac{\partial \bar{x}^\beta}{\partial x^j}\frac{\partial x^k}{\partial \bar{x}^\gamma} + \frac{\partial^2 \bar{x}^l}{\partial x^i \partial x^j}\frac{\partial x^k}{\partial \bar{x}^l}$$

or

$$\frac{\partial^2 \bar{x}^l}{\partial x^i \partial x^j}\frac{\partial x^k}{\partial \bar{x}^l} = \left\{ {k \atop i\;j} \right\} - \overline{\left\{ {\gamma \atop \alpha\;\beta} \right\}}\frac{\partial \bar{x}^\alpha}{\partial x^i}\frac{\partial \bar{x}^\beta}{\partial x^j}\frac{\partial x^k}{\partial \bar{x}^\gamma}$$

or

$$\frac{\partial \bar{x}}{\partial x^i}\frac{\partial \bar{x}}{\partial x^j}\frac{\partial x^k}{\partial \bar{x}} = 0$$

or

$$_{l\ m}{}^{k} = 0;\ \text{multiplying}\ \frac{\partial x^i}{\partial \bar{x}^l}\frac{\partial x^j}{\partial \bar{x}^m}\frac{\partial \bar{x}^p}{\partial x^k}$$

or

$$l\ m\ = 0;\quad _l = \begin{matrix} 1; & \text{for} & = l \\ 0; & \text{for} & \neq l \end{matrix};\ \text{etc.}$$

or

$$\bar{R}^h_{ijk} = 0;\quad \text{i.e.}\ R^h_{ijk} = 0:$$

Since if a tensor vanishes in one co-ordinate system, then it vanishes in all systems. It follows that Eq. (4.46) is a solution of $R^h_{ijk} = 0$; which is given. Hence, co-ordinate system $\bar{x}^i$ exists, and

$$\frac{\partial \bar{g}_{ij}}{\partial \bar{x}^k} = 0 \Rightarrow \bar{g}_{ij} = \text{constant}.$$

Consequently, a co-ordinate system $\bar{x}^i$ exists relative to which $\bar{g}_{ij}$ is constant. Hence, V_N is locally flat.

EXAMPLE 4.2.8 Determine whether the following metric is flat and/or Euclidean:

$$ds^2 = (dx^1)^2\quad (x^2)^2(dx^2)^2;\quad N = 2:$$

Solution: For the given metric, we have $g_{11} = 1;\ g_{12} = 0 = g_{21};\ g_{22} = \ (x^2)^2$: Since $g = \ (x^2)^2$; so the reciprocal tensors g^{ij} are given by

$$g^{11} = 1;\quad g^{12} = 0 = g^{21};\quad g^{22} = \frac{1}{(x^2)^2}:$$

Since the metric is not positive definite, it cannot be Euclidean. The only non-vanishing Christoffel symbol of second kind is $\,^{2}_{2\,2} = (x^2)^3$: Using Eq. (4.6), the Riemannian curvature tensors R_{ijk} can be written as

$$R^1_{212} = \frac{\partial}{\partial x^2}\,{}^{1}_{2\,1} + \frac{\partial}{\partial x^1}\,{}^{1}_{2\,2} + \,{}^{1}_{\ 1}\ \,{}_{2\,2}\ \,{}^{1}_{\ 2}\ \,{}_{2\,1} = 0:$$

$$R^2_{212} = \frac{\partial}{\partial x^2}\,{}^{2}_{2\,1} + \frac{\partial}{\partial x^1}\,{}^{2}_{2\,2} + \,{}^{2}_{\ 1}\ \,{}_{2\,2}\ \,{}^{2}_{\ 2}\ \,{}_{2\,1} = 0:$$

Using Eq. (4.13), the covariant curvature tensor is given by

$$R_{1212} = g_{1} \ R_{212} = g_{11}R^{1}_{212} + g_{12}R^{2}_{212} = 0:$$

Hence, the given space is flat.

EXAMPLE 4.2.9 Consider the Riemannian metric

$$ds^2 = (dx^1)^2 + 4(x^2)^2(dx^2)^2 + 4(x^3)^2(dx^3)^2 \quad 4(dx^4)^2(dx^4)^2:$$

(a) Calculate the Riemannian curvature. (b) Find the solution $(\bar{x}^i)$, by considering that the space is flat.

Solution: (a) For the given metric, we have $g_{11} = 1;\ g_{22} = 4(x^2)^2; g_{33} = 4(x^3)^2$ and $g_{44} = \quad 4(x^4)^2$: Since $g = \quad 64(x^2x^3x^4)^2$; so the reciprocal tensors g^{ij} are given by

$$g^{11} = 1; \quad g^{22} = \frac{1}{4(x^2)^2}; \quad g^{33} = \frac{1}{4(x^3)^2}; \quad g^{44} = \quad \frac{1}{4(x^4)^2}:$$

The non-vanishing Christoffel symbols of second kind are

$$\genfrac{}{}{0pt}{}{2}{2\ 2} = \frac{1}{x^2}; \quad \genfrac{}{}{0pt}{}{3}{3\ 3} = \frac{1}{x^3} \text{ and } \genfrac{}{}{0pt}{}{4}{4\ 4} = \frac{1}{x^4}:$$

Because $\genfrac{}{}{0pt}{}{i}{j\ k} = 0$ unless $i = j = k$; the partial derivative terms drop out of Eq. (4.6), leaving

$$R_{ijk} = \genfrac{}{}{0pt}{}{r}{i\ k}\ \genfrac{}{}{0pt}{}{}{r\ j} \qquad \genfrac{}{}{0pt}{}{r}{i\ j}\ \genfrac{}{}{0pt}{}{}{r\ k}$$

$$= \qquad\qquad = 0; \text{ (not summed)},$$

which in turn implies that $R_{hijk} = 0$ and $\ = 0$:
(b) For the above calculated Christoffel symbols, system (4.43) becomes,

$$\frac{\partial u_1}{\partial x^1} = 0; \quad \frac{\partial u_2}{\partial x^2} = \frac{u_2}{x^2}; \quad \frac{\partial u_3}{\partial x^3} = \frac{u_3}{x^3}; \quad \frac{\partial u_4}{\partial x^4} = \frac{u_4}{x^4};$$

with $\frac{\partial u_i}{\partial x^j} = 0$ for $i \neq j$: Integrating,

$$u_1 = f_1\ x^2; x^3; x^4\ ;\ u_2 = x^2 f_2\ x^1; x^3; x^4\ ;$$

$$u_3 = x^3 f_3\ x^1; x^2; x^4\ ;\ u_4 = x^4 f_4\ x^1; x^2; x^3$$

for arbitrary functions f_i. But the remaining part of Eq. (4.43), $\frac{\partial \omega}{\partial x^i} = u_i$, gives rise to the compatibility relations $\frac{\partial u_i}{\partial x^j} = \frac{\partial u_j}{\partial x^i}$, which is satisfied only if $f_i = c_i$ = constant. Therefore,

$$\omega = a_1 x^1 + a_2 (x^2)^2 + a_3 (x^3)^2 + a_4 (x^4)^2 + a_5$$

and the transformation must be of the general form,

$$\bar{x}^k = a^k_1 x^1 + a^k_2 (x^2)^2 + a^k_3 (x^3)^2 + a^k_4 (x^4)^2 + a^k_5; \quad a^k_i \text{ constants.}$$

EXAMPLE 4.2.10 For the Euclidean space under the following metric:

$$ds^2 = [(x^1)^2 + (x^2)^2](dx^1)^2 + [(x^1)^2 + (x^2)^2](dx^2)^2 + (dx^3)^2$$

exhibit a transformation from the co-ordinate system (x^i) to a rectangular system $(\bar{x}^i)$.

Solution: For the given metric, we have $g_{11} = (x^1)^2 + (x^2)^2 = g_{22}$, $g_{33} = 1$; $g_{ij} = 0 = g_{ji}$; $j \neq i$. Since $g = [(x^1)^2 + (x^2)^2]^2$, so the reciprocal tensors g^{ij} are given by

$$g^{11} = \frac{1}{(x^1)^2 + (x^2)^2}; \quad g^{22} = \frac{1}{(x^1)^2 + (x^2)^2}; \quad g^{33} = 1.$$

The non-vanishing Christoffel symbols of second kind are

$$\left\{\begin{matrix}1\\1\;1\end{matrix}\right\} = \frac{x^1}{(x^1)^2 + (x^2)^2} = \left\{\begin{matrix}2\\1\;2\end{matrix}\right\}; \quad \left\{\begin{matrix}1\\2\;2\end{matrix}\right\} = -\frac{x^1}{(x^1)^2 + (x^2)^2}$$

$$\left\{\begin{matrix}1\\1\;2\end{matrix}\right\} = \frac{x^2}{(x^1)^2 + (x^2)^2} = \left\{\begin{matrix}2\\2\;2\end{matrix}\right\}; \quad \left\{\begin{matrix}2\\1\;1\end{matrix}\right\} = -\frac{x^2}{(x^1)^2 + (x^2)^2}.$$

For the above calculated Christoffel symbols, system Eq. (4.43) becomes,

$$\frac{\partial u_1}{\partial x^1} = \frac{x^1 u_1 - x^2 u_2}{\sqrt{g}}; \quad \frac{\partial u_1}{\partial x^2} = \frac{x^2 u_1 + x^1 u_2}{\sqrt{g}}; \quad \frac{\partial u_1}{\partial x^3} = 0; \tag{i}$$

$$\frac{\partial u_2}{\partial x^1} = \frac{x^2 u_1 + x^1 u_2}{\sqrt{g}}; \quad \frac{\partial u_2}{\partial x^2} = \frac{-x^1 u_1 + x^2 u_2}{\sqrt{g}}; \quad \frac{\partial u_2}{\partial x^3} = 0; \tag{ii}$$

$$\frac{\partial u_3}{\partial x^1} = 0; \quad \frac{\partial u_3}{\partial x^2} = 0; \quad \frac{\partial u_3}{\partial x^3} = 0. \tag{iii}$$

Thus, u_1 and u_2 are functions of x^1, x^2 alone, and u_3 = constant. Since the g_{ij} are all polynomials of degree 2 in x^1, x^2, use the method of undetermined coefficients, assuming polynomial forms

$$u_i = a_i (x^1)^2 + b_i x^1 x^2 + c_i (x^2)^2 + d_i x^1 + e_i x^2 + f_i; \quad i = 1, 2.$$

The compatibility relations $\frac{\partial u_1}{\partial x^2} = \frac{\partial u_2}{\partial x^1}$ implied by the second part of Eq. (i) and the first part of Eq. (ii) require,

$$b_1 = 2a_2; \quad 2c_1 = b_2; \quad e_1 = d_2.$$

Similarly, the compatibility relations $\frac{\partial u_1}{\partial x^1} = -\frac{\partial u_2}{\partial x^2}$ imply

$$2a_1 = -b_2; \quad b_1 = -2c_2; \quad d_1 = -e_2.$$

From the first part of Eq. (i), we get

$$a_1 = 0 = a_2; \quad c_1 = -b_2; \; b_1 = -c_2; \; d_1 = -e_2; \; f_1 = 0 = -f_2.$$
$$\Rightarrow \quad b_1 = b_2 = c_1 = c_2 = 0.$$

Thus, the solution can be written in the form

$$u_1 = ax^1 + bx^2; \quad u_2 = bx^1 - ax^2; \quad u_3 = c;$$

where we are redenoting the constants d_1 and e_1. The first part of Eq. (4.43) gives

$$\frac{\partial \phi}{\partial x^1} = ax^1 + bx^2; \quad \frac{\partial \phi}{\partial x^2} = bx^1 - ax^2; \quad \frac{\partial \phi}{\partial x^3} = c;$$

or

$$\phi = \frac{a}{2}(x^1)^2 + bx^1x^2 - \frac{a}{2}(x^2)^2 + cx^3 + d$$

or

$$\bar{x}^k = \frac{a^k}{2}(x^1)^2 + b^k x^1 x^2 - \frac{a^k}{2}(x^2)^2 + c^k x^3 \text{ with } d = 0.$$

It is clear that we take $c^1 = c^2 = 0 = a^3 = b^3$ and $c^3 = 1$;

$$\bar{x}^1 = \frac{1}{2}a^1(x^1)^2 + b^1x^1x^2 - \frac{1}{2}a^1(x^2)^2$$
$$\bar{x}^2 = \frac{1}{2}a^2(x^1)^2 + b^2x^1x^2 - \frac{1}{2}a^2(x^2)^2; \quad \bar{x}^3 = x^3.$$

Now, the Jacobian matrix J satisfies $J^TJ = G$. Here

$$J = \begin{bmatrix} a^1(x^1)^2 + b^1x^1x^2 & b^1x^1x^2 - \frac{1}{2}a^1(x^2)^2 & 0 \\ a^2(x^1)^2 + b^2x^1x^2 & b^2x^1x^2 - \frac{1}{2}a^2(x^2)^2 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

$$\Rightarrow \quad (a^1)^2 + (a^2)^2 = 1; \; a^1b^1 + a^2b^2 = 0; \; (b^1)^2 + (b^2)^2 = 1; \quad \text{as } J^TJ = G.$$

So, take $a^1 = 0; a^2 = 1; b^2 = 0; b^1 = 1.$ Finally, the transformation is given by

$$\bar{x}^1 = x^1x^2; \quad \bar{x}^2 = \frac{1}{2}[(x^1)^2 - (x^2)^2]; \quad \bar{x}^3 = x^3.$$

Deduction 4.2.3 Let the metric tensors g_{ij} are constants, then all the partial derivatives of g_{ij} are zero. Consequently, all Christoffel symbols will vanish and all $R_{ijkl} = 0$; i.e. $= 0$: Thus, by Theorem 4.2.2, the space is flat. If $\overline{x} = Ax$; then $J = A$ and

$$G = J^T \overline{G} J = A^T \overline{G} A:$$

However, since G is real and symmetric, its eigenvectors form an orthogonal matrix which we now choose as A, with

$$AGA^{-1} = AGA^T = D; \quad D = \text{diagonal matrix}$$

of eigenvalues of G. Hence, $\overline{G} = AGA^T = D$: Hence, if the metric tensor is constant, the space is flat and the transformation $\overline{x} = Ax$; where A is a rank N matrix of eigenvalues $G = (g_{ij})$, diagonalises the metric, i.e. $\overline{g}_{ij} = 0$ for $i \neq j$:

EXAMPLE 4.2.11 Find the signature of the flat metric

$$ds^2 = 4(dx^1)^2 + 5(dx^2)^2 - 2(dx^4)^2 - 4dx^2dx^3 - 4dx^2dx^4 - 10dx^3dx^4:$$

Solution: For the given metric, we have $g_{11} = 4$; $g_{22} = 5$; $g_{33} = -2$; $g_{44} = 2$, $g_{23} = -2$; $g_{24} = -2$ and $g_{34} = -5$: Now, we find the eigenvalues of $G = (g_{ij})$. The characteristic equation is

$$|G - \lambda I| = \begin{vmatrix} 4-\lambda & 0 & 0 & 0 \\ 0 & 5-\lambda & -2 & -2 \\ 0 & -2 & -2-\lambda & -5 \\ 0 & -2 & -5 & 2-\lambda \end{vmatrix} = 0$$

$$\Rightarrow \quad (4-\lambda)(5-\lambda)(37-\lambda^2) = 0$$

$$\Rightarrow \quad \lambda = 4; 5; \pm\sqrt{37}:$$

This means that there is a transformation which changes the metric into the form

$$\begin{aligned} ds^2 &= 4(dx^1)^2 + 5(dx^2)^2 + \sqrt{37}\,(dx^3)^2 - (dx^4)^2 \\ &= (d\overline{x}^1)^2 + (d\overline{x}^2)^2 + (d\overline{x}^3)^2 - (d\overline{x}^4)^2; \end{aligned}$$

with the obvious change of co-ordinates. Hence, the signature is $(+ + + -)$; or some permutation thereof.

4.2.5 Projective Curvature Tensor

The projective curvature tensor or Weyl tensor, denoted by W_{hijk}; is defined by

$$W_{hijk} = R_{hijk} + \frac{1}{1-N}\left(g_{kl} R_{hj} - g_{kh} R_{ij}\right); \qquad (4.47)$$

where R_{hijk} is the Riemannian curvature tensor and R_{ij} is the Ricci tensor.

Theorem 4.2.3 A necessary and sufficient condition that a Riemannian space V_N $(N > 3)$ to be of constant Riemannian curvature is that the Weyl tensor vanishes identically throughout V_N.

Proof: Let be the constant Riemannian curvature of V_N given by

$$= \frac{p^h q^i p^j q^k R_{hijk}}{p^h q^i p^j q^k [g_{hj} g_{ik} \quad g_{ij} g_{hk}]} = \text{constant}:$$

Since is constant, it is independent of the orientation determined by p^i and q^j and hence

$$= \frac{R_{hijk}}{g_{hj} g_{ik} \quad g_{ij} g_{hk}} \;) \; R_{hijk} = (\quad g_{ij} g_{hk} + g_{hj} g_{ik})$$

or

$$g^{hk} R_{hijk} = g^{hk} (\quad g_{ij} g_{hk} + g_{hj} g_{ik})$$

or

$$R_{ij} = g^{hk} (\quad N g_{ij} + {}^{k}_{j} g_{ik}) = (1 \quad N) g_{ij}$$

or

$$g^{ij} R_{ij} = (1 \quad N) g^{ij} g_{ij}$$

or

$$R = (1 \quad N) N \quad) \; R_{ij} = \frac{R}{N} g_{ij} : \tag{4.48}$$

Since is constant, Eq. (4.48) shows that R is constant. Now, the Weyl tensor W_{hijk} is given by

$$\begin{aligned} W_{hijk} &= R_{hijk} + \frac{1}{1 \quad N} (g_{ki} R_{hj} \quad g_{kh} R_{ij}) \\ &= R_{hijk} + \frac{1}{1 \quad N} \; g_{ki} \frac{1}{N} R g_{hj} \quad g_{kh} \frac{1}{N} R g_{ij} \\ &= R_{hijk} + \frac{R}{N (1 \quad N)} [g_{ki} g_{hj} \quad g_{hk} g_{ij}] \\ &= R_{hijk} + \frac{R}{N (1 \quad N)} \frac{1}{} R_{hijk} \\ &= R_{hijk} + \frac{1}{} R_{hijk} = 2 R_{hijk} = 0; \text{ as } \quad \text{is constant.} \end{aligned}$$

Thus, the condition is necessary. Conversely, let the Weyl tensor $W_{hijk} = 0$; we have to prove that $= \text{constant}$. Since $W_{hijk} = 0$; we have

$$R_{hijk} + \frac{1}{1 \quad N} [g_{ik} R_{hj} \quad g_{hk} R_{ij}] = 0$$

or

$$g^{hk}R_{hijk} + \frac{1}{1 \quad N}\,{}^{h}\, g^{hk}g_{ik}R_{hj} \qquad g^{hk}g_{hk}R_{ij}\,{}^{i} = 0$$

or

$$R_{ij} + \frac{1}{1 \quad N}\,{}^{h}\;{}^{h}_{i}R_{hj} \qquad NR_{ij}\,{}^{i} = 0$$

or

$$R_{ij} + \frac{1}{1 \quad N}[R_{ij} \qquad NR_{ij}] = 0$$

or

$$R_{ij} + \frac{1 \quad N}{1 \quad N}R_{ij} = 0\ ) \quad R_{ij} = 0$$

or

$$R_{ij} = g^{hk}R_{hijk} = 0\ ) \quad \text{either } g^{hk} = 0 \text{ or } R_{hijk} = 0:$$

If $R_{hijk} = 0$; then the Riemann curvature $= 0$: If $g^{hk} = 0$; then $g_{hk} = 0$ and hence,

$$= \frac{p^h q^i p^j q^k R_{hijk}}{p^h q^i p^j q^k [g_{hj}\, g_{ik} \qquad 0 g_{ij}]} = \frac{p^h q^i p^j q^k R_{hijk}}{p^h q^i p^j q^k g_{hj}\, g_{ik}}$$

$$= \frac{p^h q^i p^j q^k R_{hijk}}{(p^h p^j g_{hj})(q^i q^k g_{ik})}$$

$$= \frac{p^h q^i p^j q^k R_{hijk}}{p^2 q^2};\ p^2 = 1 = \ g_{hj}\, p^h p^j;\ \ q^2 = 1 = \ g_{ik}\, q^i q^k$$

or

$$= p^h q^i p^j q^k R_{hijk} = \text{constant as } R_{ij} = 0:$$

Since 0 is constant, in either case is a constant. Thus, the condition is necessary.

4.2.6 Uniform Vector Field

The construction of a field of parallel vectors is possible only when the Riemann{Christoffel curvature tensor vanishes. Here, we have to prove that, when Riemann{Christoffel tensor vanishes the differential equations

$$A_{;} = \frac{@A}{@x} \qquad {}^{a} \qquad A_a = 0$$

are integrable. Let A be a covariant vector, then by definition

$$\frac{@A}{@x} \quad A \qquad\qquad = A_{;} = 0; \tag{4.49}$$

where we suppose that $A_{;} = 0$: We want to show that Eq. (4.49) can be integrated only when curvature tensor $R^a_{ijk} = 0$: From Eq. (4.49) we get,

$$\frac{\partial A}{\partial x} dx = A \qquad dx$$

or

$$\int \frac{\partial A}{\partial x} dx = \int A \qquad dx$$

or

$$\int dA = A = \int A \qquad dx : \tag{4.50}$$

This means that Eq. (4.49) is integrable only when the right hand side of Eq. (4.50) is integrable, for which the condition is $A \qquad dx$ must be perfect differential. So, we can write,

$$A \qquad dx = dB = \frac{\partial B}{\partial x} dx$$

or

$$A \qquad \frac{\partial B}{\partial x} \quad dx = 0$$

or

$$A \qquad = \frac{\partial B}{\partial x}; \quad \text{as } dx \text{ is arbitrary.} \tag{4.51}$$

Differentiating Eq. (4.51) with respect to x, we get

$$\frac{\partial A}{\partial x} \qquad + A \frac{\partial}{\partial x} \qquad = \frac{\partial^2 B}{\partial x \partial x}: \tag{4.52}$$

Interchanging and we get

$$\frac{\partial A}{\partial x} \qquad + A \frac{\partial}{\partial x} \qquad = \frac{\partial^2 B}{\partial x \partial x}: \tag{4.53}$$

Subtracting Eq. (4.53) from Eq. (4.52), we get

$$\frac{\partial A}{\partial x} \qquad + A \frac{\partial}{\partial x} \qquad \frac{\partial A}{\partial x} \qquad A \frac{\partial}{\partial x} \qquad = 0$$

or

$$A_c \quad {}^{c} \quad + A \frac{@}{@x} \qquad\qquad A_c \quad {}^{c}$$

$$A_c \frac{@}{@x} \quad {}^{c} \qquad = 0 \text{ by Eq. } (4.49)$$

or

$$A_c \quad {}^{c} \quad + A_c \frac{@}{@x} \quad {}^{c} \qquad\qquad {}^{c} \quad A_c \quad A_c \frac{@}{@x} \quad {}^{c} \qquad = 0$$

or

$${}^{c} \quad + \frac{@}{@x} \quad {}^{c} \qquad\qquad {}^{c} \qquad \frac{@}{@x} \quad {}^{c} \qquad A_c = 0$$

or

$$\frac{@}{@x} \quad {}^{c} \quad + \frac{@}{@x} \quad {}^{c} \qquad\qquad {}^{c} \quad + \qquad {}^{c} \qquad A_c = 0$$

or

$$R^{c} \quad A_c = 0; \quad \text{i.e. } R^{c} \quad = 0; \text{ as } A_c \text{ is arbitrary}:$$

Thus, we see that the RHS of Eq. (4.50) is integrable only when the curvature tensor vanishes. Consequently, Eq. (4.49) is integrable only when $R^{c} \quad = 0$:

Now, we can carry the vector A to any point by parallel displacement. This gives a unique result independent of the path of transfer. If a vector is displaced in this way we obtain a uniform vector field. Thus, the construction of uniform vector field is only possible when the curvature tensor vanishes.

4.3 Einstein Space

Einstein space is defined as a space which is homogeneous with regard to the Ricci tensor R_{ij}. Thus, a space for which

$$R_{ij} = \ g_{ij}; \qquad = \text{invariant at all points} \tag{4.54}$$

at every point of the space, then that space is called Einstein space. Inner multiplication of g^{ij} shows that

$$g^{ij} R_{ij} = \ g^{ij} g_{ij} \ ) \quad R = \ N: \tag{4.55}$$

Thus for an Einstein space,

$$R_{ij} = \ g_{ij} = \frac{1}{N} R g_{ij}: \tag{4.56}$$

Hence, for an Einstein space Eq. (4.56) holds at every point of the space.

Theorem 4.3.1 A space of constant curvature is an Einstein space.

Proof: Let the Riemannian curvature κ at P of V_N for the orientation determined by p^i and q^i, is given in Eq. (4.34) as

$$\kappa = \frac{p^h q^i p^j q^k R_{hijk}}{p^h q^i p^j q^k \left[g_{hj} g_{ik} - g_{ij} g_{kh}\right]}.$$

Since κ is constant and independent of the orientation so,

$$\kappa = \frac{R_{hijk}}{g_{hj} g_{ik} - g_{ij} g_{kh}}$$

or

$$R_{hijk} = \kappa\left[g_{hj} g_{ik} - g_{ij} g_{kh}\right].$$

Multiplying by g^{hk}, we get

$$\kappa\, g^{hk}\left[g_{hj} g_{ik} - g_{ij} g_{kh}\right] = g^{hk} R_{hijk}$$

or

$$\kappa\left(\delta^h_i g_{hj} - N g_{ij}\right) = R_{ij}, \quad \text{since}, g^{hk} R_{hijk} = R_{ij}$$

or

$$\kappa\left(g_{ij} - N g_{ij}\right) = R_{ij}$$

or

$$\kappa(1-N)\, g_{ij}\, g^{ij} = R_{ij}\, g^{ij}; \text{ multiplying by } g^{ij}$$

or

$$\kappa N(1-N) = R, \quad \text{as} R_{ij}\, g^{ij} = R.$$

Therefore,

$$R_{ij} = \kappa(1-N) g_{ij} \frac{R}{N(1-N)} = \frac{R}{N} g_{ij}.$$

This is the necessary and sufficient condition for the space V_N to be Einstein space.

EXAMPLE 4.3.1 If $g^{ik} R_{kj} = R^i_j$ and $g^{ij} R_{ij} = R$, show that $R^i_{j;i} = \frac{1}{2}\frac{\partial R}{\partial x^j}$. Hence, show that for an Einstein space, the scalar curvature R is constant.

Solution: Here, we use the Bianchi identity, Eq. (4.20), $R_{pkjt;i} + R_{pkti;j} + R_{pkij;t} = 0$. The covariant differentiation of the relation $g^{ik} R_{kj} = R^i_j$ with respect to x^l is given by

$$R^i_{j;l} = g^{ik}_{;l} R_{kj} + g^{ik} R_{kj;l} = g^{ik} R_{kj;l}; \quad \text{as} \, g^{ik}_{;l} = 0.$$

Thus, the divergence of R^i_j is given by

$$R^i_{j;i} = g^{ik}R_{kj;i} = g^{ik}R^t_{kjt;i}\ ;\ \text{as } R^t_{kit} = R_{kj}$$
$$= g^{ik}\left(g^{pt}R_{pkjt}\right)_{;i}\ ;\quad \text{as } g^{pt}R_{pkjt} = R^t_{kjt}$$
$$= g^{ik}g^{pt}R_{pkjt;i}\ ;\quad \text{as } g^{pt}_{;i} = 0$$
$$= g^{ik}g^{pt}\left[R_{pkti;j} + R_{pkij;t}\right] = g^{pt}\left[g^{ik}R_{pkti;j} + g^{ik}R_{pkij;t}\right]$$
$$= g^{pt}\left[g^{ki}R_{kpti;j} + g^{ik}R_{kpji;t}\right]$$
$$\text{as } R_{kpti} = R_{pkti} \text{ and } R_{kpji} = R_{pkij}$$
$$= g^{pt}\left(R^i_{pti;j} + R^i_{pji;t}\right) = g^{pt}\left[R_{pt;j} + R_{pj;t}\right]$$
$$= \left(g^{pt}R_{pt}\right)_{;j}\quad g^{pt}R_{pj;t} = R_{;j}\quad R^t_{j;t} = R_{;j}\quad R^i_{j;i}$$
replacing the dummy index t by i

or

$$2R^i_{j;i} = R_{;j} = \frac{\partial R}{\partial x^j} \Rightarrow R^i_{j;i} = \frac{1}{2}\frac{\partial R}{\partial x^j}.$$

For an Einstein space, $R_{ij} = \frac{R}{N}g_{ij}$, therefore,

$$g^{ki}R_{ij} = \frac{R}{N}g_{ij}\,g^{ki} \Rightarrow R^k_j = \frac{R}{N}\delta^k_j$$

or

$$R^k_{j;k} = \frac{1}{N}R_{;k}\,\delta^k_j = \frac{1}{N}R_{;j}$$

or

$$\frac{1}{2}R_{;j} = \frac{1}{N}R_{;j} \Rightarrow R_{;j} = 0;\quad \text{for } N > 2.$$

Therefore, for an Einstein space, the scalar curvature R is constant.

EXAMPLE 4.3.2 For a V_2 referred to an orthogonal system of parametric curves $(g_{12} = 0)$, show that

$$R_{12} = 0;\quad R_{11}g_{22} = R_{22}g_{11} = R_{1221}$$
$$R = g^{ij}R_{ij} = \frac{2R_{1221}}{g_{11}g_{22}};\quad \text{consequently, } R_{ij} = \frac{R}{2}g_{ij}.$$

Hence, show that V_2 is an Einstein space.

Solution: Given that, in a V_2, $g_{12} = 0$ so that $g^{12} = 0$. Also,

$$g^{ij} = \frac{1}{g_{ij}} \Rightarrow g^{11} = \frac{1}{g_{11}}, \quad g^{22} = \frac{1}{g_{22}}.$$

The metric of V_2 is given by

$$\begin{aligned} ds^2 &= g_{ij}\, dx^i dx^j, \quad i, j = 1, 2 \\ &= g_{11}(dx^1)^2 + g_{22}(dx^2)^2, \quad \text{as } g_{12} = 0. \end{aligned}$$

Also, we know that $g^{hk}R_{hijk} = R_{ij}$ and

$$g = \begin{vmatrix} g_{11} & g_{12} \\ g_{21} & g_{22} \end{vmatrix} = \begin{vmatrix} g_{11} & 0 \\ 0 & g_{22} \end{vmatrix} = g_{11}g_{22}.$$

(a) Here, we have to show that $R_{12} = 0$. For this,

$$\begin{aligned} R_{12} &= g^{hk}R_{h12k} = g^{h1}R_{h121} + g^{h2}R_{h122} = g^{h1}R_{h121}, \quad \text{as } R_{h122} = 0 \\ &= g^{11}R_{1121} + g^{21}R_{2121} = 0, \quad \text{as } g^{12} = 0 \text{ and } R_{1121} = 0. \end{aligned}$$

(b) Using the relation $g^{hk}R_{hijk} = R_{ij}$ we get

$$R_{11} = g^{hk}R_{h11k} = g^{2k}R_{211k} = g^{22}R_{2112} = \frac{R_{2112}}{g_{22}}.$$

$$R_{22} = g^{hk}R_{h22k} = g^{1k}R_{122k} = g^{11}R_{1221} = \frac{R_{1221}}{g_{11}}.$$

Since $R_{2112} = R_{1221}$, it follows that, $R_{11}g_{22} = R_{1221} = R_{22}g_{11}$. Therefore, in a two-dimensional Riemannian space the components of a Ricci tensor are proportional to the components of a metric tensor.

(c) From the definition of R, we get

$$\begin{aligned} R &= g^{ij}R_{ij} = g^{i1}R_{i1} + g^{i2}R_{i2} \\ &= g^{11}R_{11} + g^{22}R_{22}, \quad \text{as } g^{12} = 0 \\ &= \frac{R_{11}}{g_{11}} + \frac{R_{22}}{g_{22}} = \frac{R_{1221}}{g_{22}g_{11}} + \frac{R_{1221}}{g_{11}g_{22}} \\ &= \frac{2R_{1221}}{g_{11}g_{22}}, \quad \text{as } R_{2112} = R_{1221}. \end{aligned}$$

(d) From (c), we see that

$$R = \frac{2R_{1221}}{g_{11}g_{22}} = \frac{2R_{1221}}{g}; \quad \text{as } g = g_{11}g_{22}$$
$$\Rightarrow \quad R_{1221} = \frac{1}{2}Rg.$$

Therefore, the relation in (b) can be written in the form

$$R_{11}g_{22} = \frac{1}{2}Rg = R_{22}g_{11}$$

from which it follows that

$$R_{11} = \frac{Rg}{2g_{22}} = \frac{Rg_{11}g_{22}}{2g_{22}} = \frac{1}{2}Rg_{11}$$
$$R_{22} = \frac{Rg}{2g_{11}} = \frac{Rg_{11}g_{22}}{2g_{11}} = \frac{1}{2}Rg_{22}$$
$$R_{12} = \frac{1}{2}Rg_{12} = 0; \quad \text{as } g_{12} = 0.$$

Consequently, we get $R_{ij} = \frac{R}{2}g_{ij}$. This shows that V_2 is an Einstein space.

4.4 Mean Curvature

Let $\lambda^i_{h|}$ be the components of unit vector in a direction at a point P of a V_N. Let $\lambda^i_{k|}$ be the components of unit vector forming an orthogonal ennuple. One vector out of N vectors $\lambda^i_{k|}$ is $\lambda^i_{h|}$ and hence, we can say that $\lambda^i_{k|}$ are components of $N-1$ vectors where $h \neq k$ and $k = 1, 2, \ldots, N$.

Let the Riemannian curvature at P of V_N for the orientation determined by $\lambda^i_{h|}$ and $\lambda^i_{k|}$ $(k \neq h)$ be denoted by K_{hk} and is given by

$$K_{hk} = \frac{\lambda^p_{h|}\lambda^q_{k|}\lambda^r_{h|}\lambda^s_{k|}R_{pqrs}}{\lambda^p_{h|}\lambda^q_{k|}\lambda^r_{h|}\lambda^s_{k|}(g_{pr}g_{qs} - g_{ps}g_{qr})}$$
$$= \frac{\lambda^p_{h|}\lambda^q_{k|}\lambda^r_{h|}\lambda^s_{k|}R_{pqrs}}{\left(\lambda^p_{h|}\lambda^r_{h|}g_{pr}\right)\left(\lambda^q_{k|}\lambda^s_{k|}g_{qs}\right) - \left(\lambda^p_{h|}\lambda^s_{k|}g_{ps}\right)\left(\lambda^q_{k|}\lambda^r_{h|}g_{qr}\right)}. \tag{4.57}$$

Since unit vectors $\lambda^i_{h|}$ and $\lambda^i_{k|}$ are orthogonal, so,

$$\lambda^p_{h|}\lambda^r_{h|}g_{pr} = 1 \text{ and } \lambda^p_{h|}\lambda^s_{k|}g_{ps} = 0.$$

Therefore, from Eq. (4.57), we get

$$K_{hk} = \frac{{}^{p}_{hj}\,{}^{q}_{kj}\,{}^{r}_{hj}\,{}^{s}_{kj}R_{pqrs}}{1{:}1 \quad 0{:}0} = \quad {}^{p}_{hj}\,{}^{q}_{kj}\,{}^{r}_{kj}\,{}^{s}_{kj}R_{pqrs}: \qquad (4.58)$$

Since the right-hand side of Eq. (4.58) vanishes for $h = k$, and so we say K_{hh} is equal to zero. Let $M_h = \sum_{k=1}^{N} K_{hk}$: Hence from Eq. (4.58) we have,

$$\sum_{k=1}^{N} K_{hk} = M_h = \sum_{k=1}^{N} {}^{p}_{hj}\,{}^{q}_{kj}\,{}^{r}_{hj}\,{}^{s}_{kj}R_{pqrs}$$

$$= {}^{p}_{hj}\,{}^{q}_{hj}\sum_{k=1}^{N} {}^{q}_{kj}\,{}^{s}_{kj}R_{pqrs}$$

$$= {}^{p}_{hj}\,{}^{r}_{hj}g^{qs}R_{pqrs}; \text{ as } \sum_{k=1}^{N} {}^{q}_{kj}\,{}^{s}_{kj} = g^{qs}$$

$$= \quad {}^{p}_{hj}\,{}^{r}_{hj}g^{qs}R_{qprs} = \quad {}^{p}_{hj}\,{}^{r}_{hj}R^{s}_{pqs} = \quad {}^{p}_{hj}\,{}^{r}_{hj}R_{pr}: \qquad (4.59)$$

This shows that M_h is independent of $(N \quad 1)$ orthogonal direction choosen to complete an orthogonal ennuple. Here, M_h is defined as mean curvature or Riccian curvature of V_N for the direction ${}^{p}_{hj}$: Summing Eq. (4.58) over the N mutually orthogonal directions, we get

$$\sum_{h=1}^{N} M_h = \sum_{h=1}^{N} {}^{p}_{hj}\,{}^{r}_{hj}R_{pr} = \quad g^{pr}R_{pr} = \quad R;$$

where R is the scalar curvature. This proves that the sum of mean curvatures for N mutual orthogonal directions is independent of the directions chosen to complete an orthogonal ennuple and has the value R:

4.4.1 Ricci's Principal Directions

Let us suppose that ${}^{i}_{hj}$ is not a unit vector and therefore, the mean curvature M_h in this case is given by

$$M_h = \frac{R_{ij}\,{}^{i}_{hj}\,{}^{j}_{hj}}{g_{ij}\,{}^{i}_{hj}\,{}^{j}_{hj}} \quad) \quad (R_{ij} + M_h g_{ij})\,{}^{i}_{hj}\,{}^{j}_{hj} = 0:$$

Differentiating this equation with respect to ${}^{i}_{hj}$; we get

$$\frac{@M_h}{@\,{}^{i}_{hj}} g_{jk}\,{}^{j}_{hj}\,{}^{k}_{hj} + 2(R_{ij} + M_h g_{ij})\,{}^{j}_{hj} = 0:$$

For extreme value of M_h, we must have $\frac{\partial M_h}{\partial\, {}^{i}_{hj}} = 0$; and so

$$(R_{ij} + M_h g_{ij})\ {}^{j}_{hj} = 0;$$

which are called Ricci's principal direction of the space and they are principal directions of Ricci tensor R_{ij}.

EXAMPLE 4.4.1 For a two-dimensional manifold, prove that $K_{pq} = \frac{R}{2}$:

Solution: In V_2, we know R_{1212} is the only non-vanishing Riemann–Christoffel tensor given by

$$R_{1212} = \frac{1}{2}Rg;\ R = \text{ total curvature.}$$

Let the Riemannian curvature at P of V_N for the orientation determined by ${}^{i}_{pj}$ and ${}^{i}_{qj}$ $(q \neq p)$ be denoted by K_{pq} and from Eq. (4.57) we get,

$$K_{pq} = \frac{{}^{h}_{pj}\ {}^{i}_{qj}\ {}^{j}_{pj}\ {}^{k}_{qj} R_{hijk}}{{}^{h}_{pj}\ {}^{i}_{qj}\ {}^{j}_{pj}\ {}^{k}_{qj} (g_{hj}\, g_{ik} \quad g_{hk}\, g_{ij})}$$

$$= \frac{{}^{1}_{pj}\ {}^{2}_{qj}\ {}^{1}_{pj}\ {}^{2}_{qj} R_{1212}}{{}^{1}_{pj}\ {}^{2}_{qj}\ {}^{1}_{pj}\ {}^{2}_{qj} (g_{11}g_{22} \quad g_{12}g_{21})} = \frac{R_{1212}}{g_{12}^2 \quad g_{11}g_{22}} = \frac{R_{1212}}{g} = \frac{1}{2}R:$$

4.5 Geodesics in a V_N

Consider a curve : $x^i = x^i(t)$ in a V_N, an N-dimensional Riemannian space, on it and let $x^i(t)$ be the co-ordinates of a general point P on it. Let the points A and B of the path correspond, respectively, to the value t_1 and t_2 of the parameter.

Consider two points on the path close to each other with co-ordinates x^i and $x^i + dx^i$. Let the parameter take values t and $t + dt$ corresponding to these two points, respectively. The interval ds between the two points is given by

$$ds^2 = g_{ij}\, dx^i dx^j = g_{ij} \frac{dx^i}{dt}\frac{dx^j}{dt} dt^2: \tag{4.60}$$

The total interval between A and B along the path therefore,

$$S = \int_{t_1}^{t_2} \sqrt{g_{ij} \frac{dx^i}{dt}\frac{dx^j}{dt}}\, dt$$

$$= \int_A^B F(x^i; \underline{x}^i)dt;\ \text{say; where } F(x^i; \underline{x}^i) = \sqrt{g_{ij}\, \underline{x}^i \underline{x}^j}: \tag{4.61}$$

In order C is a geodesic, integral Eq. (4.61) should be stationary. In order that integral Eq. (4.61) is stationary, we have the Euler-Lagrange condition,

$$\frac{\partial F}{\partial x^l} - \frac{d}{dt}\left(\frac{\partial F}{\partial \dot x^l}\right) = 0$$

or

$$\frac{1}{2\dot s}\frac{\partial g_{ij}}{\partial x^l}\dot x^i \dot x^j - \left[-\frac{\ddot s}{\dot s} g_{li}\dot x^i + \frac{1}{\dot s}\frac{\partial g_{li}}{\partial x^j}\dot x^j \dot x^i + \frac{1}{\dot s} g_{li}\ddot x^i\right] = 0$$

or

$$g_{li}\ddot x^i - \frac{\ddot s}{\dot s} g_{li}\dot x^i + [li;j]\dot x^i \dot x^j = 0. \tag{4.62}$$

Multiplying this relation by g^{lm} and perform summation over l, we get

$$\ddot x^m - \frac{\ddot s}{\dot s}\dot x^m + \left\{ {m \atop i\ j} \right\}\dot x^i \dot x^j = 0. \tag{4.63}$$

Equation (4.63) of geodesic can be further simplified by taking $s = t$, so that $\dot s = 1$; $\ddot s = 0$; and therefore, Eq. (4.63) becomes

$$\frac{d^2x^i}{ds^2} + \left\{ {i \atop j\ k} \right\}\frac{dx^j}{ds}\frac{dx^k}{ds} = 0; \tag{4.64}$$

where s itself is chosen as the parameter. This, of course, represents a set of N coupled differential equations. Equation (4.64) is known as geodesic equation in V_N.

EXAMPLE 4.5.1 Show that on the surface of a sphere all great circles are geodesics while no other circle is a geodesic.

Solution: The components of the metric tensor on the surface of a sphere of radius a are $g_{11} = a^2; g_{22} = a^2\sin^2\theta; g_{12} = g_{21} = 0$ and $g = a^4\sin^2\theta$ so that the metric is $ds^2 = a^2(d\theta)^2 + a^2\sin^2\theta\,(d\phi)^2$. The non-vanishing Christoffel symbols are

$$\left\{ {2 \atop 1\ 2} \right\} = \cot\theta = \left\{ {2 \atop 2\ 1} \right\}; \quad \left\{ {1 \atop 2\ 2} \right\} = -\sin\theta\cos\theta.$$

Thus, the geodesic equation reduces to (with $\theta = x^1$; $\phi = x^2$)

$$\frac{d^2\theta}{ds^2} - \sin\theta\cos\theta\left(\frac{d\phi}{ds}\right)^2 = 0 \tag{i}$$

$$\frac{d^2\phi}{ds^2} + 2\cot\theta\frac{d\theta}{ds}\frac{d\phi}{ds} = 0. \tag{ii}$$

(a) Consider a great circle on the surface of the sphere and choose the z-axis ($\theta = 0$) to be normal to the plane of the circle, so that the great circle is the equator. The parametric equation of the great circle is

$$\theta = \frac{\pi}{2}; \quad \phi = cs + d; \quad c \neq 0; \qquad \text{(iii)}$$

where c and d are independent of s, θ and ϕ. It is evident that Eq. (iii) satisfy Eqs. (i) and (ii), so that the great circle is a geodesic. Since the choice of the polar axis $\theta = 0$ is arbitrary, it follows that any great circle is a geodesic.

(b) Consider a circle on the sphere such that the plane of the circle does not pass through the centre of the sphere. Again, choose the direction $\theta = 0$ to be normal to the plane of the circle so that the parametric equation of the circle is

$$\theta = \theta_0; \quad \phi = ps + q; \quad \theta_0 \in (0, \pi) - \left\{\frac{\pi}{2}\right\}; \quad p \neq 0; \qquad \text{(iv)}$$

where p and q are independent of s, θ and ϕ. On substitution, it is seen that Eq. (ii) is satisfied but Eq. (i) is reduces to

$$p^2 \sin\theta_0 \cos\theta_0 = 0.$$

The conditions on θ_0 and p of Eq. (iv) show that this equation cannot be satisfied, proving that the circle is not a geodesic.

Now, we find the lines of shortest distance of the sphere. From Eq. (4.61), we have,

$$S = a \int_A^B F(x^i, \dot{x}^i)\,dt,$$

where

$$F(x^i, \dot{x}^i) = \sqrt{g_{ij}\dot{x}^i\dot{x}^j} = \sqrt{1 + \dot{\phi}^2 \sin^2\theta}.$$

In order ϕ is a geodesic, then Euler–Lagrange equation reduces to,

$$F_{\dot{\phi}} = \text{constant} \Rightarrow \frac{\dot{\phi}\sin^2\theta}{\sqrt{1 + \dot{\phi}^2 \sin^2\theta}} = c$$

$$\Rightarrow \dot{\phi}^2 = \frac{c^2}{\sin^4\theta - c^2\sin^2\theta} = \frac{c^2\operatorname{cosec}^4\theta}{(1 - c^2) - c^2\cot^2\theta}$$

$$\Rightarrow \dot{\phi} = \frac{k\operatorname{cosec}^2\theta}{\sqrt{1 - k^2\cot^2\theta}};\ k^2 = \frac{c^2}{1 - c^2}$$

$$\Rightarrow \phi = \alpha - \sin^{-1}(k\cot\theta); \ \text{i.e.}\ \sin(\alpha - \phi) = k\cot\theta.$$

Let us verify these curves are great circles. Multiplied last equation by sin , we get

$$(\ \sin\ \cos\ )\sin \qquad (\ \sin\ \sin\ )\cos\ = k\ \cos$$

or

$$x \sin \qquad y \cos\ = kz:$$

This represents a plane through the centre of the sphere, and the section of the sphere by this plane is a great circle.

4.5.1 Parallel Vector Fields

In an Euclidean space, a vector field $A_i(x^j)$ is said to be a field of parallel vectors if the components A_i are constants, i.e. $A_{i;j} = 0$; i.e. or, suppose that a vector A_i defined at a point x^j undergoes a displacement dx^j to the point $x^j + dx^j$, where, the vector becomes $A_i + \partial A_i$: We shall say that A_i undergoes a parallel displacement if $\frac{\partial A_i}{\partial x_j} = 0$: For example, a uniform electric field is a field of parallel vectors; the gravitational field of the earth in a sufficiently small region of space is a field of parallel vectors.

Here, our object is to generalise the concept of parallel displacement of surface vectors and tensors in Riemannian space, due to Levi Civita. Let us consider a space curve ; total of points, whose co-ordinates satisfy equation of the form

$$: \ x^i = x^i(t); \tag{4.65}$$

where x^i (belongs to the class C^1) are functions of a single parameter t. Let a vector A be localised at some point P of whose components A^i are functions of t. If we construct at every point of , a vector equal to A in magnitude and parallel to it in direction, we obtain what is known as a parallel field of vectors along the curve . We have shown in Chapter 3 that if A_i is a vector, its co-ordinate derivative $\frac{\partial A_i}{\partial x_j}$ is not a tensor, but the intrinsic derivative $\frac{A_i}{t}$ along the curve Eq. (4.65) is a tensor. To retain the tensor character, therefore, we must define the parallel displacement of a tensor in a Riemannian space differently. If A^i is a solution of the system of differential equation

$$\frac{A^i}{t} = \frac{dA^i}{dt} + \begin{matrix} i \\ j\ \ k \end{matrix}\ A^j \frac{dx^k}{ds} \tag{4.66}$$

then the vectors A^i are said to form a parallel vector field along the curve given by Eq. (4.65). We say that if the vector A is a parallel field along , then the vectors A do not change along the curve. Thus, the vector A suffers a parallel displacement along if the intrinsic derivative of the tensor along the curve vanishes, (Figure 4.1), i.e.

$$A^i_{;j}\frac{dx^i}{dt} = \frac{A^i}{t} = 0: \tag{4.67}$$

Conversely, we can show that every solution of system Eq. (4.67) yields a parallel vector field along Γ. Indeed, from the theory of differential equations it is known that

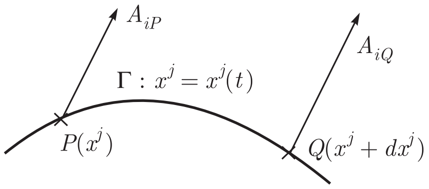

Figure 4.1: Parallel vectors A_{iP} and A_{iQ}.

this system of first order differential equations has a unique solution when the values of the components A^i are specified at a point of Γ. But the vector field formed by constructing a family of vectors of fixed lengths, parallel to a given vector, satisfies the system. Hence, every solution of Eq. (4.67) satisfies the initial conditions must form a parallel field along Γ.

In other words, we say that A^i is parallely displaced with respect to Riemannian space along the curve Γ, if Eq. (4.67) holds at all points of Γ. Thus, we have a field of parallel vectors, if,

$$A^i_{;j}\frac{dx^i}{dt} = 0 \Rightarrow g_{ik}\left(A^i_{;j}\frac{dx^j}{dt}\right) = 0 \Rightarrow \left(g_{ik}A^i\right)_{;j}\frac{dx^j}{dt} = 0$$

$$\Rightarrow A_{k;j}\frac{dx^j}{dt} = 0; \text{i.e. } A_{i;j}\frac{dx^j}{dt} = 0$$

or

$$\frac{dA^i}{dx^j} + \left\{\begin{matrix} i \\ j \end{matrix}\right\} A \frac{dx^j}{dt} = 0$$

or

$$\frac{dA^i}{dt} + \left\{\begin{matrix} i \\ j \end{matrix}\right\} A \frac{dx^j}{dt} = 0$$

or

$$dA^i = -\left\{\begin{matrix} i \\ j\ k \end{matrix}\right\} A^j dx^k \tag{4.68}$$

along the curve. The converse follows, as previously, for the existence and uniqueness of solution of such systems of differential equations. Similarly, the condition for a parallel displacement of a covariant vector A_i is

$$dA_i = \left\{\begin{matrix} j \\ i\ k \end{matrix}\right\} A_j dx^k. \tag{4.69}$$

Also, it follows from the observation that $A_{i;k} = g_i \ A_{;k}$ whenever $A_i = g_{ij} A^j$: Thus, the increments in A^i and A_i due to a displacement dx^j along the curve are given by Eqs. (4.68) and (4.69), respectively.

Result 4.5.1 Now, consider a point $P(x^i)$ and two displacements dx^i and $\ x^i$ from P giving rise to the points $Q(x^i + dx^i)$ and $R(x^i + \ x^i)$, respectively, as seen in Figure 4.2.

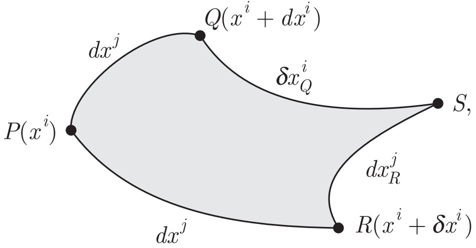

Figure 4.2: Generalised infinitesimal parallelogram.

Imagine the segment $PR = \ x^i$ being parallely displaced such that as the end point P goes to Q, the other end R goes to S. The displacement QS will be

$$QS \quad x^i_Q = \ x^i + d(\ x^i); \tag{4.70}$$

which makes the co-ordinates of the point S;

$$S \quad x^i + dx^i + \ x^i_Q \ = \ x^i + dx^i + \ x^i + d(\ x^i) \ ; \tag{4.71}$$

where by Eq. (4.68), we have

$$d(\ x^i) = \ \begin{matrix} i \\ j\ k \end{matrix}_P \ x_j \, dx^k : \tag{4.72}$$

The subscript P on the Christoffel symbol means is to be evaluated at P. Similarly, imagine the segment $PQ = dx^i$ being parallely displaced such that as the point P goes to R, the other end Q goes to S^0. The displacement RS^0 will be given by

$$RS = dx^i_R = \ x^i + d(\ x^i); \tag{4.73}$$

which makes the co-ordinates of the point S^0

$$S^0 \quad x^i + dx^i + \ x^i_R \ = \ x^i + \ x^i + dx^i + \ (dx^i) \ ; \tag{4.74}$$

$$\text{where,} \quad (dx^i) = \ \begin{matrix} i \\ j\ k \end{matrix}_P dx_j \ x^k = \ \begin{matrix} i \\ j\ k \end{matrix}_P dx_k \ x^j ; \tag{4.75}$$

which follows by interchanging j and k and using the symmetric property of the Christoffel symbol. Equations (4.72) and (4.75) show that $d(\ x^i) = \ (dx^i)$ indicating that the point S^0 coincides with S. The closed figure $PQRS$ can be regarded as the generalised infinitesimal parallelogram with opposite sides parallel to each other in the Riemannian space.

Result 4.5.2 (Curvature of Riemannian space V_N). Here we have introduced the curvature tensor by considering the parallel displacement of a vector along two different paths. Consider an infinitesimal parallelogram PQRS (Figure 4.3) as described with adjacent sides $PQ = dx^i$ and $PR = \delta x^i$. Imagine a constravariant vector A^i_p defined at the point P being parally displaced is the following two ways:

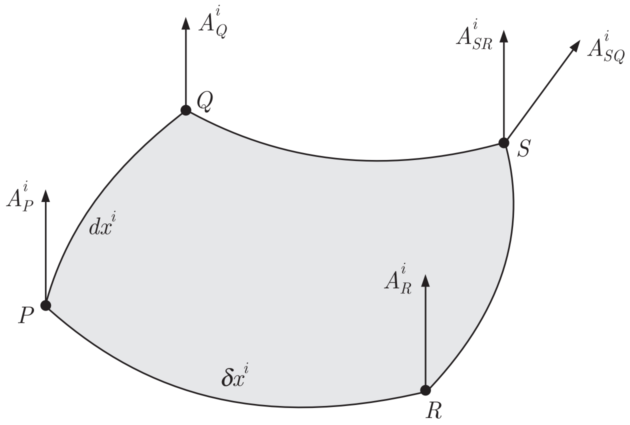

Figure 4.3: Curvature of Riemannian space.

(i) Displace A^i_p parallely from P to Q resulting A^i_Q and then displace A^i_Q parallely from Q to S giving the vector A^i_{SQ}.

(ii) Displace A^i_p parallely from P to R giving A^i_R parallely from R to S resulting the vector A^i_{SR}.

The vector A^i_Q obtained by a parallel displacement of A^i_P is given by

$$A^i_Q = A^i_P + dA^i_P; \quad \text{where } dA^i_P = -\left\{ {i \atop j\;k} \right\}_P A^j_P dx^k. \qquad \text{(i)}$$

This vector is parallely displaced from Q to S resulting the vector A^i_{SQ} which will be given by

$$A^i_{SQ} = A^i_Q + \delta A^i_Q = A^i_Q - \left\{ {i \atop l\;h} \right\}_Q A^l_Q\, \delta x^h. \qquad \text{(ii)}$$

The Christoffel symbol depends on the metric tensor which in turn is a function of co-ordinates. For a small displacement, we can therefore write

$$\left\{ {i \atop l\;h} \right\}_Q = \left\{ {i \atop l\;h} \right\}_P + \left\{ {i \atop l\;h} \right\}_{P;m} dx^m \qquad \text{(iii)}$$

where $\left\{ {i \atop l\ h} \right\}_{P;m} = \frac{\partial}{\partial x^m} \left\{ {i \atop l\ h} \right\}_{\text{at } P}$. Substituting Eqs. (iii) and (i) in Eq. (ii), we have

$$A^i_{SQ} = A^i_P - \left\{ {i \atop j\ k} \right\}_P A^j_P\, dx^k - \left[\left\{ {i \atop l\ h} \right\}_P + \left\{ {i \atop l\ h} \right\}_{P;m} dx^m \right]$$

$$\left(A^l_P - \left\{ {l \atop j\ k} \right\}_P A^j_P\, dx^k \right) \delta x^h$$

$$= A^i - \left\{ {i \atop j\ k} \right\} A^j\, dx^k - \left\{ {i \atop l\ h} \right\} A^l\, \delta x^h - \left\{ {i \atop l\ h} \right\}_{;m} A^l\, dx^m\, \delta x^h$$

$$+ \left\{ {i \atop l\ h} \right\} \left\{ {l \atop j\ k} \right\} A^j\, dx^k\, dx^h + O\left[(dx^k)^3 \right]; \qquad \text{(iv)}$$

where we have dropped the subscript P from the right hand side of (iv) because all the quantities are to be evaluated at P. The vector A^i_{SR} obtained by a parallel displacement along the path PRS will be simply given by an interchange of dx^i and δx^i in the expression for A^i_{SQ}:

$$A^i_{SR} = A^i - \left\{ {i \atop j\ k} \right\} A^j\, \delta x^k - \left\{ {i \atop l\ h} \right\} A^l dx^h - \left\{ {i \atop l\ h} \right\}_{;m} A^l\, \delta x^m\, dx^h$$

$$+ \left\{ {l \atop l\ h} \right\} \left\{ {l \atop j\ k} \right\} A^j\, \delta x^k\, dx^h + O\left[(dx^k)^3 \right]. \qquad \text{(v)}$$

Subtracting (iv) from (v) we get

$$A^i_{SR} - A^i_{SR} = \left\{ {i \atop l\ h} \right\}_{;m} A^l\, dx^m\, \delta x^h - \left\{ {i \atop l\ h} \right\}_{;m} A^l\, \delta x^m\, dx^h$$

$$+ \left\{ {i \atop l\ h} \right\} \left\{ {l \atop j\ k} \right\} A^j\, \delta x^k\, dx^h - \left\{ {i \atop l\ h} \right\} \left\{ {l \atop j\ k} \right\} A^j\, dx^k\, \delta x^h. \qquad \text{(vi)}$$

Replacing l by j and m by k in the first two terms on the right hand side of (vi) and interchanging k and h in the second and third terms, the Eq. (vi) can be written as

$$A^i_{SR} - A^i_{SQ} = R^i_{jhk}\, A^j\, dx^k\, \delta x^h; \qquad \text{(vii)}$$

where

$$R^i_{jkh} = \left\{ {i \atop j\ h} \right\}_{;k} - \left\{ {i \atop j\ k} \right\}_{;h} + \left\{ {i \atop l\ k} \right\} \left\{ {i \atop j\ h} \right\} - \left\{ {i \atop l\ h} \right\} \left\{ {l \atop j\ k} \right\} \qquad \text{(viii)}$$

Since A^j; dx^k and x^h are arbitrary vectors, if follows from quotient law that R^i_{jkh} is a tensor of rank four, known as the Riemann-Christoffel curvature tensor. It is independent of the vector A^i and depends only on the metric tensor and its first and second derivatives.

It follows that if a tensor is parallely displaced along a closed curve until we come back to the starting point, the resulting vector will not necessarily be the same as the original vector in a non-Euclidean space.

EXAMPLE 4.5.2 If A^i and B^i are two vectors of constant magnitudes and undergo parallel displacements along a curve then show that they are inclined at a constant angle.

Solution: Let the two vectors A^i and B^i be of constant magnitudes, so that their lengths do not change as we move along the curve . Let these vectors suffer parallel displacement along a curve , so by hypothesis

$$\frac{A^i}{t} = 0 = \frac{B^i}{t};$$

at each point of . The angle between the vectors A^i and B^i, is given by

$$\cos\ = g_{ij}A^iB^j:$$

The angle between the vectors A^i and B^i remains fixed as the parameter t is allowed to change. Here, $g_{ij}A^iB^j$ is an invariant. Differentiating intrinsically with respect to t, we get

$$\frac{}{t}(\cos\ ) = \frac{}{t}\ g_{ij}A^iB^j = \frac{d}{dt}\ g_{ij}A^iB^j$$

$$= g_{ij}\frac{A^i}{t}B^j + g_{ij}A^i\frac{B^j}{t} = g_{ij}\ 0\ B^j + g_{ij}A^i\ 0 = 0$$

or

$$\frac{d}{dt}(\cos\ ) = 0\ )\ \cos\ = \text{constant, i.e.}\ = \text{constant}:$$

Thus, we conclude that $g_{ij}A^iB^j$ is constant along . It follows directly from the result that, if $A^i = B^i$, then $g_{ij}A^iA^j = A^2$ is constant along and this implies = constant.

EXAMPLE 4.5.3 Prove that geodesics are autoparallel curves.

Solution: To prove the result, it is enough to prove that the unit tangent vector, say ^{i}, suffers a parallel displacement along a geodesic curve . Let $: x^i = x^i(t)$ be a geodesic in a Riemannian space. Then the co-ordinates of the points on the geodesic satisfy the geodesic equation,

$$\frac{d^2x^i}{dt^2} + \begin{matrix} i \\ j\ \ k \end{matrix} \quad \frac{dx^j}{dt}\frac{dx^k}{dt} = 0$$

or

$$\frac{d\ \ ^i}{dt} + \begin{matrix} i \\ j\ \ k \end{matrix} \quad {}^j \frac{dx^k}{dt} = 0$$

or

$$\frac{@\ \ ^i}{@x^k} + \begin{matrix} i \\ j\ \ k \end{matrix} \quad {}^j \ \frac{dx^k}{dt} = 0$$

or

$${}^i_{;k}\frac{dx^k}{dt} = 0; \ \text{i.e.} \ \ {}^i_{;j}\frac{dx^j}{dt} = 0;$$

at each point on . This result shows that the unit vectors form a system of parallel vectors along a geodesic. Hence, it follows from the definition of parallel displacement that the field of tangent vectors to a geodesic is a field of parallel vectors.

EXAMPLE 4.5.4 Any vector of constant magnitude which undergoes a parallel displacement along a geodesic is inclined at a constant angle to the curve.

Solution: Let a vector A^i of constant magnitude undergo a parallel displacement along a geodesic , so that,

$$\frac{A^{\ i}}{t} = A^i_{;j}\frac{dx^j}{dt} = 0$$

at each point of . Let $\ ^i$ be a unit tangent vector to the curve , so that,

$$\frac{\ \ ^i}{t} = \ {}^i_{;j}\frac{dx^j}{dt} = 0$$

at each point of , since geodesics are autoparallel curves. Let be the angle between the vector $\ ^i$ and a curve at any point of , i.e. is the angle between A^i and $\ ^i$, then,

$$A^i\ \ _i = A\ \ 1\ \ \cos$$

or

$$\frac{d}{dt}(A\cos\ \ ) = \frac{d}{dt}(A^i\ \ _i) = (\ A^i\ \ _i)_{;j}\frac{dx^i}{dt}$$

or

$$A\sin\ \ \frac{d}{dt} = A^i_{;j}\frac{dx^j}{dt}\ \ _i + A^i\ \ _{i;j}\frac{dx^j}{dt}$$

$$= 0t_1 + A^i 0 = 0:$$

or

$$\sin \frac{d}{dt} = 0; \quad \text{as } A \neq 0;$$

or

$$\sin \;= 0 \quad \text{or} \quad \frac{d}{dt} = 0 \Rightarrow \quad = 0 \quad \text{or} \quad = \text{constant}:$$

EXAMPLE 4.5.5 If the intrinsic derivative of a vector vanishes, then show that the magnitude of the vector is constant.

Solution: Let the intrinsic derivative of a vector A^i be zero so that

$$\frac{A^i}{t} = A^i_{;j}\frac{dx^j}{dt} = 0:$$

We have to show that $A^2 = A^iA_i$ is constant. Differentiating both sides with respect to a parameter t and noting that the intrinsic derivative of a scalar is ordinary derivative, we have

$$\frac{dA^2}{dt} = \frac{d}{dt}\;A^iA_i \;=\; A^iA_i\;_{;j}\frac{dx^j}{ds}$$

$$= A^i_{;j}\frac{dx^j}{dt}A_i + A^iA_{i;j}\frac{dx^j}{ds} = 0A_i + A^i0 = 0$$

or

$$A^2 = \text{constant} \Rightarrow A = \text{constant}:$$

Thus, if the derived vector of a given vector A in the direction of a given curve vanishes at all points of a curve, then the magnitude of the vector is constant. If A^i forms a field of parallel vectors along the curve $x^i = x(t)$, then we have

$$\frac{A^i}{t} = A^i_{;j}\frac{dx^j}{dt} = 0:$$

Then similarly, as above we can show that A = constant. Thus, the magnitude of a vector remain invariant under parallel displacement.

EXAMPLE 4.5.6 Show that the parallel displacement of a vector taken all around a circle on the surface of a sphere does not lead back to the same vector except when the circle is a great circle, that is, a geodesic.

Solution: Choose spherical polar co-ordinates $x^1 =$ and $x^2 =$ on the surface of the sphere. The non-vanishing Christoffel symbols are,

$$\genfrac{}{}{0pt}{}{2}{1\;2} = \cot \;= \genfrac{}{}{0pt}{}{2}{2\;1}; \quad \genfrac{}{}{0pt}{}{1}{2\;2} = \quad \sin \;\cos:$$

Choose a small circle normal to the polar axis so that its parametric equation is

$$\theta = \alpha; \quad \phi = ps + q; \quad p \neq 0 \text{ with } \frac{d\alpha}{dt} = 0.$$

Consider a vector $A^i = (A^1, A^2)$ at a point on the circle which may be taken to be $\phi = 0$. When the vector is displaced parallely along the circle, the change in its components is given, from Eq. (4.69), by

$$\frac{dA^1}{dt} = -\Gamma^1_{jk} A^j \frac{dx^k}{dt} = A^2 \sin\alpha \cos\alpha \frac{d\phi}{dt} \qquad \text{(i)}$$

$$\frac{dA^2}{dt} = -\Gamma^2_{jk} A^j \frac{dx^k}{dt} = -A^1 \cot\alpha \frac{d\phi}{dt}. \qquad \text{(ii)}$$

Now, for any function f of θ and ϕ through t, we have

$$\frac{df}{dt} = \frac{\partial f}{\partial \theta}\frac{d\theta}{dt} + \frac{\partial f}{\partial \phi}\frac{d\phi}{dt} = \frac{\partial f}{\partial \phi}\frac{d\phi}{dt},$$

which reduces Eqs. (i) and (ii) to

$$\frac{\partial A^1}{\partial \phi} = A^2 \sin\alpha \cos\alpha; \quad \frac{\partial A^2}{\partial \phi} = -A^1 \cot\alpha. \qquad \text{(iii)}$$

Differentiating once again with respect to ϕ and substituting one in the other, Eq. (iii) give rise to the decoupled equations

$$\frac{\partial^2 A^1}{\partial \phi^2} = -A^1 \cos^2\alpha; \quad \frac{\partial^2 A^2}{\partial \phi^2} = -A^2 \cos^2\alpha; \qquad \text{(iv)}$$

whose solution, consistent with Eq. (iii), is

$$A^1 = \sin\alpha\,[c\cos(\phi\cos\alpha) + d\sin(\phi\cos\alpha)]$$

$$A^2 = d\cos(\phi\cos\alpha) - c\sin(\phi\cos\alpha).$$

At $\phi = 0$, the components of the vector are given by

$$A^1(\phi = 0) = c\sin\alpha; \quad A^2(\phi = 0) = d; \qquad \text{(v)}$$

whereas, after parallel displacement once around the circle, the components become,

$$A^1(\phi = 2\pi) = \sin\alpha\,[c\cos(2\pi\cos\alpha) + d\sin(2\pi\cos\alpha)]$$

$$A^2(\phi = 2\pi) = d\cos(2\pi\cos\alpha) - c\sin(2\pi\cos\alpha);$$

which are not the same as those given by Eq. (v) except when $\alpha = \frac{\pi}{2}$; i.e. when the displacement is along the geodesic.

4.6 Exercises

1. Obtain the geodesic equations in cylindrical co-ordinates and spherical polar co-ordinates for the three-dimensional Euclidean space.
2. Consider a great circle on the surface of a sphere and choose the polar axis to lie in the plane of the great circle is a meridian. With this choice of co-ordinates, show that any meridian on a sphere is a geodesic.
3. Show that parallel displacement of a vector along any closed curve in an Euclidean space leads back to the original vector.
4. Prove that cyclic property of the covariant curvature tensor by setting a geodesic co-ordinate system.
5. Verify that, $R_{ijkl;m} + R_{ijlm;k} + R_{ijmk;l} = 0:$
6. In a two-dimensional Riemannian space, the components of the Ricci tensor are proportional to the components of the metric tensor.
7. Given the relation
$$A^{i}_{j} = R^{i}_{j} + {}^{i}_{j}(R + \quad)$$
where ; are constants. Show that for the value of $= \frac{1}{2}$, $A^{i}_{j;i} = 0:$
8. Let in a V_2 space the line element is $ds^2 = 2f(x^1;x^2)dx^1dx^2$. Find R_{1212} for the space. Prove that the space is flat, if
$$f\frac{@^2 f}{@x^1 @x^2} = \frac{@f}{@x^1}\frac{@f}{@x^2}:$$
Show also if f is independent of at least one of the two co-ordinates x^1 and x^2, then the space is flat.
9. Prove that a necessary and sufficient condition for a Riemannian V_N $(N > 2)$, to be of constant Riemannian curvature is that the Weyl tensor vanishes identically throughout $V_N:$
10. Prove that the mean curvature in the direction ${}_i$ at a point of a V_N is the sum of $N \quad 1$ Riemmanian curvatures along the direction pairs consisting of the direction and $N \quad 1$ other directions forming with this directions an orthogonal frame.
11. Prove that the sum of mean curvatures of a V_N for a mutually orthogonal directions at a point, is independent of the ennuple chosen. Obtain the value of this sum.
12. Prove that a Riemannian metric (g_{ij}) is the Euclidean metric if and only if the Riemannian curvature is zero at all points and the metric is positive definite.
13. (a) Calculate the Riemannian curvature for the metric
$$ds^2 = (\ dx^1)^2 \quad 2x^1(dx^2)^2:$$

(b) Show that the components R_{1212} of the curvature tensor for a two-dimensional space with metric $ds^2 = dx^2 + f(x, y)dy^2$ equals

$$\frac{1}{2}\frac{\partial^2 f}{\partial x^2} + \frac{1}{4f}\quad\frac{\partial f}{\partial x}\quad^{2}.$$

(c) A two-dimensional space have the metric

$$ds^2 = f(u, v)du^2 + h(u, v)dv^2.$$

Find the components R_{1212} of the curvature tensor for the space.

14. Show that the Riemannian curvature at any point (x^i) of Riemannian 3 space in the direction $P = (0, 1, 0)$ and $Q = (1, 1, 0)$ is $\frac{1}{4}(x^1)\;\;^{2}$, if the metric is given by

$$g_{11} = 1;\;\; g_{22} = 2x^1;\;\; g_{33} = 2x^2;\;\; g_{ij} = 0,\;\; \text{for } i \neq j.$$

15. Prove that, in a V_2,

$$R_{ijkl} = \quad \frac{R}{2}[g_{ik}g_{jl} \quad g_{il}g_{jk}].$$

16. Consider the metric $ds^2 = (dx^1)^2 \quad (x^1)^2[(dx^2)^2 + (dx^3)^2]$. Show that $R_{1212} = 2$ and that, therefore, the space is not flat.

17. Prove that a Riemannian space is an Einstein space if

$$R_{ijk} = \quad\;_j\, g_{jk} \quad\;_k\, g_{ij}\quad;$$

where is a constant. Hence, show that for an Einstein space, the scalar curvature R is constant.

18. Prove Schur's theorem. If all points in some neighbourhood in a Riemannian R^N are isotropic and $N \quad 3$, then is a constant throughout that neighbourhood.

19. Verify that $ds^2 = (dx^1)^2 + (x^1)^2(dx^2)^2$ represents the Euclidean metric in polar co-ordinates.

20. Determine whether the following metric is flat and/or Euclidean:

(a) $ds^2 = (dx^1)^2 \quad (x^1)^2(dx^2)^2, N = 2.$
(b) $ds^2 = (dx^1)^2 + (x^3)^2(dx^2)^2 + (dx^3)^2.$

21. Find the isotropic points for the Riemannian metric

$$ds^2 = (\log x^2)\quad (dx^1)^2 + (dx^2)^2 + (dx^3)^2\quad ;\;\; x^2 > 1;$$

and find the curvature at those points.

22. Show that R^3 under the metric

$$g_{11} = e^{x^2}; \quad g_{22} = 1; \quad g_{33} = e^{x^2}; \quad g_{ij} = 0; \text{ for } i \neq j$$

has constant Riemannian curvature with all points isotropic, find that curvature.

23. If ${}^{j}_{i}$ is the Einstein tensor, prove that

    (a) ${}^{j}_{i;j} = \left(R^{j}_{i} \quad \tfrac{1}{2}\ {}^{j}_{i} R \right)_{;j} = 0:$

    (b) The Einstein invariant $= \ {}^{i}_{i}$, vanishes if the space is flat.

24. For a two-dimensional space (V_2), show that

$$gR_{ij} = \quad g_{ij} R_{1212} \quad \text{and} \quad gR = \quad 2R_{1212}:$$

Hence, deduce that every V_2 is an Einstein space.

25. The metric of the V_2 formed by the surface of a sphere of radius r is

$$ds^2 = r^2 d\ ^2 + r^2 \sin^2\ d\ ^2$$

in spherical polar co-ordinates. Show that the surface of a sphere is a surface of constant curvature.

26. In an Euclidean V_4, prove that the hypersurface, $x^1 = c \sin u^1 \sin u^2 \sin u^3$, $x^2 = c \sin u^1 \sin u^2 \cos u^3$, $x^3 = c \sin u^1 \cos u^2$, $x^4 = c \cos u^1$ has a constant curvature $c\ ^2$:

27. Show that an Einstein space V_3 has constant curvature.

28. In a space in which the relation

$$R_{ij}\, g_{kl} \quad R_{il}\, g_{jk} + R_{jk}\, g_{il} \quad R_{kl}\, g_{ij} = 0$$

holds, show that the space is an Einstein space.

29. Find the lines of shortest distance of a sphere of radius a.

30. Show that the magnitude of a vector and angle between two vectors remain invariant under parallel displacement.

31. If two unit vectors are such that at all points of a given curve , their intrinsic derivatives along are zero, show that they are inclined at a constant angle.

32. Show that the field of tangent vectors to a geodesic is a field of parallel vectors.

Chapter 5

Geometry of Space Curve

For the study of a curve by the method of calculus, its parametric representation is covariant. In this chapter, three vectors (tangent, normal, binormal) of fundamental importance to curve theory are discussed. A curve is determined uniquely except for position by measures of two notions associated with it, called its *curvature* and *torsion*. For a given curve there is a set of important formulas dealing with its curvature and torsion. These formulas are called *Serret–Frenet formulae*, which will be established in the next theory.

5.1 Curve Theory

A curve C in E^3 is the image of a class C^3 mapping, r, from an interval of real numbers into E^3. The moving frame of the curve

$$C: r = r(s) = \left(x^1(s), x^2(s), x^3(s)\right) \tag{5.1}$$

with the arbitrary parameter s, has been defined as an image of the real number for the arc length parameterization. Let s be the arc length. Then,

$$\begin{aligned}
r' &= T = \frac{dr}{ds} = \left(x^{1\prime}(s), x^{2\prime}(s), x^{3\prime}(s)\right)\\
r'' &= \frac{d^2r}{ds^2} = \left(x^{1\prime\prime}(s), x^{2\prime\prime}(s), x^{3\prime\prime}(s)\right) = \frac{dT}{ds} = \kappa N\\
r''' &= \frac{d^3r}{ds^3} = \left(x^{1\prime\prime\prime}(s), x^{2\prime\prime\prime}(s), x^{3\prime\prime\prime}(s)\right)\\
&= \frac{d}{ds}(\kappa N) = \kappa' N + \kappa\frac{dN}{ds} = \kappa' N + \kappa(-\kappa T + \tau B).
\end{aligned}$$

We have at once for the unit tangent vector,

$$\hat{T} = \hat{r}' = \frac{1}{|r'|}r' = \frac{1}{|r'|}\left(x^{1\prime}(s), x^{2\prime}(s), x^{3\prime}(s)\right).$$

Since $r'' = \frac{dT}{ds} = \ \hat{N}$; where N is the normal vector, we have $|r''| = \ $; and so, the unit normal vector is given by

$$\hat{N} = \frac{1}{|r''|} r'' = \frac{1}{|r''|} \ \ x_1''(s); x_2''(s); x_3''(s) \ \ :$$

  is called the curvature. The unit vector $\hat{N}$ is perpendicular to $\hat{T}$ and in the plane of the tangents at P and a consecutive point. This plane, containing two consecutive tangents and three consecutive points at P, is called the plane of curvature or the osculating plane at P. If R is any point in this plane, then the equation of the osculating plane

$$[R \quad r; \hat{T}; \hat{N}] = 0; \text{i:e:} \ [R \quad r; r'; r''] = 0:$$

The unit vectors $\hat{T}$ and $\hat{N}$ are perpendicular to each other, and their plane is the plane of curvature. The straight line through P parallel to $\hat{N}$ is called the principal normal at P (Figure 5.1). If R be the current point on the line, its equation is

$$R = r + u\hat{N}:$$

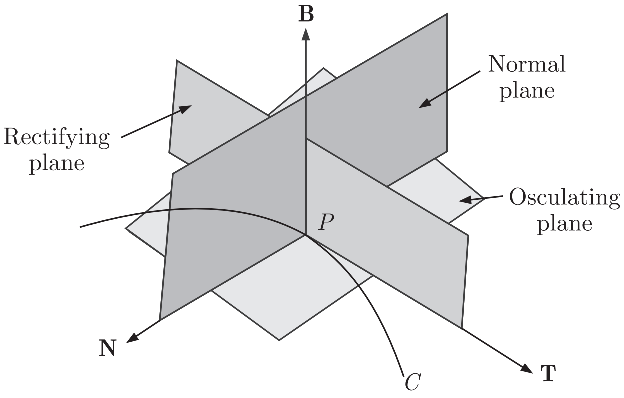

Figure 5.1: Planes.

The circle of curvature at P is the circle passing through three points on the curve ultimately coincident at P. Its radius P $= \frac{1}{\ }$ is called the radius of curvature, and its centre C the centre of curvature. This circle is clearly lies on the osculating plane at P, and its curvature is the same as that of the curve at P, for it has two consecutive tangents in common with the centre. The centre of curvature C lies on the principal normal, and

$$\overrightarrow{PC} = \ \hat{N} = \frac{1}{\ }\hat{N}$$

The direction cosines of $\hat{N}$ can be written as

$$\hat{N} = \frac{d\hat{T}}{ds} = \ r'':$$

Finally, for the binormal vector, we have

$$B = T \quad N = r^0 \quad \frac{1}{jr^{00}j} r^{00} = \frac{1}{jr^{00}j}\; r^0 \quad r^{00}:$$

The positive direction along the binormal is taken as that of B, just as the positive direction along the principal normal is that of $\hat{N}$. The equation of the binormal is

$$R = r + uB:$$

Since B is a vector of constant length, it follows that $\frac{dB}{ds}$ is perpendicular to B. Moreover differentiating the relation T.B = 0 with respect to s we find

$$kN \quad B + T \quad \frac{dB}{ds} = 0$$

) T $\frac{dB}{ds}$ = 0, as N is perpendicular to B. This equation shows that $\frac{dB}{ds}$ is perpendicular to T, which is perpendicular to B, and must therefore parallel to N. We may then write

$$\frac{dB}{ds} = \qquad N:$$

In this equation $\frac{dT}{ds}$ = N; the scalar measures the arc-rate of turning of the unit vector T, so here measures the arc-rate of turning of the unit vector B. This rate of turning of binormal is called the torsion of the curve at the point P. It is of course the rate of rotation of the osculating plane. The negative sign indicates that the torsion is regarded as positive when the rotation of the binormal as s increase is in the same sense as that of a right handed screw travelling in the direction of T. Now

$$\frac{dN}{ds} = \frac{d}{ds}(B \quad T) = \quad N \quad T + B \quad (\; N)$$

$$= \quad B \quad T:$$

The formulas for $\frac{dT}{ds}; \frac{dN}{ds}$ and $\frac{dB}{ds}$ gather together gives

$$\frac{dT}{ds} = \; N; \; \frac{dN}{ds} = \; B \quad T; \; \frac{dB}{ds} = \quad N:$$

These equations are the vector equivalents of the Serret{Frenet formulae for the derivatives of the direction cosines of the tangent, the principal normal and the binormal. Therefore

$$\frac{}{s}\begin{pmatrix} T \\ N \\ B \end{pmatrix} = \begin{pmatrix} 0 & & 0 \\ & 0 & \\ 0 & & 0 \end{pmatrix}\begin{pmatrix} T \\ N \\ B \end{pmatrix}$$

which is the Serret{Frenet formulae in the matrix form. The coefficient matrix is Skew-symmetric.

Now, we have to calculate $[r', r'', r''']$ as

$$r', r'', r''' = T;\ N;\ {}'N + (\ T + \ B)$$
$$= [T;\ N;\ B] = {}^2\ [T; N; B] = {}^2$$
$$) \qquad = \frac{1}{{}^2}\ r', r'', r''' = \frac{1}{|r''|^2}\ r', r'', r''':$$

An alternative formula giving the square of the torsion, may be deduced from the expression for r''' found above. On squaring this and diving throughout by ^{2} we obtain the result

$${}^2 = \frac{1}{{}^2}\, r'''^2 \qquad {}^2 \qquad \frac{'}{}^{2}:$$

By analogy with the relation that the radius of curvature is equal to the reciprocal of the curvature, it is customary to speak of the reciprocal of the torsion, and to denote it by . So $= \frac{1}{}$. But there is no circle of torsion or centre of torsion associated with the curve in the same way as the circle and centre of curvature.

Let the equation of the curve be

$$C : r = r(t) = x^1(t); x^2(t); x^3(t)\ ; \tag{5.2}$$

where t is a parameter. Therefore,

$$\dot r = \frac{dr}{dt} = \dot x^1(t); \dot x^2(t); \dot x^3(t) = \frac{dr}{ds}\frac{ds}{dt} = r'\dot s = \dot s T$$
$$r = \frac{d^2r}{dt^2} = x^1(t); x^2(t); x^3(t) = \frac{d}{dt}(\dot s T) = sT + \ \dot s^2 N$$
$$\dot r = \frac{d^3r}{dt^3} = \dot x^1(t); \dot x^2(t); \dot x^3(t) = \frac{d}{dt}\ sT + \ \dot s^2 N$$
$$= \frac{dT}{ds}\dot s s + T\dot s + \dot{\ }\dot s^2 N + (\ T + \ B)\,\dot s^3 + 2\ \dot s s N:$$

Since $T\ r = s$, so, $s = \frac{\dot r\ r}{|\dot r|}$: Therefore,

$$r = sT + \ \dot s^2 N = \frac{\dot r\ r}{|\dot r|}\frac{\dot r}{|\dot r|} + \ \dot s^2 N$$

or

$$N = \frac{1}{|\dot r|^2}\ r \qquad \frac{(r\ r)}{|\dot r|^2}\dot r$$

or

$$= \frac{1}{|\dot r|^2}\ |r| \qquad \frac{(r\ r)}{|\dot r|} = \frac{|\dot r\ \ r|}{|\dot r|^3}:$$

Therefore, the normal vector is given by

$$N = \frac{1}{\kappa|\dot{r}|^2}\left[\ddot{r} - \frac{(\dot{r}\cdot\ddot{r})}{|\dot{r}|^2}\dot{r}\right].$$

Now, we have to calculate $\left[\dot{r}, \ddot{r}, \dddot{r}\right]$ as

$$\left[\dot{r}, \ddot{r}, \dddot{r}\right] = \left[\dot{s}T, \kappa\dot{s}^2N, \kappa\tau\dot{s}^3B\right] = \kappa^2\tau\dot{s}^6[T, N, B] = \kappa^2\tau\dot{s}^6.$$

or

$$\tau = \frac{\left[\dot{r}, \ddot{r}, \dddot{r}\right]}{\kappa^2\dot{s}^6} = \frac{\left[\dot{r}, \ddot{r}, \dddot{r}\right]}{|\dot{r}\times\ddot{r}|^2}\frac{|\dot{r}|^6}{|\dot{r}|^6} = \frac{\left[\dot{r}, \ddot{r}, \dddot{r}\right]}{|\dot{r}\times\ddot{r}|^2},$$

which is the expression for torsion.

5.2 Plane Curve

When the curve $x^i = f^i(s)$ lies on the plane, then it is defined as a plane curve. Every planner curve has a principal normal vector. A necessary and sufficient condition for a curve $x^i = f^i(s)$ lies on a plane is

$$\begin{vmatrix} f^{1\prime} & f^{2\prime} & f^{3\prime} \\ f^{1\prime\prime} & f^{2\prime\prime} & f^{3\prime\prime} \\ f^{1\prime\prime\prime} & f^{2\prime\prime\prime} & f^{3\prime\prime\prime} \end{vmatrix} = 0.$$

Let the curve $x^i = f^i(s)$ lie on the plane

$$a_1x^1 + a_2x^2 + a_3x^3 + a_0 = 0$$

or

$$a_1f^1(s) + a_2f^2(s) + a_3f^3(s) + a_0 = 0.$$

Differentiate with respect to s thrice, we have

$$a_1f^{1\prime}(s) + a_2f^{2\prime}(s) + a_3f^{3\prime}(s) = 0$$

$$a_1f^{1\prime\prime}(s) + a_2f^{2\prime\prime}(s) + a_3f^{3\prime\prime}(s) = 0$$

$$a_1f^{1\prime\prime\prime}(s) + a_2f^{2\prime\prime\prime}(s) + a_3f^{3\prime\prime\prime}(s) = 0.$$

Eliminating a_1, a_2, a_3 from the above three equations, we get

$$\begin{vmatrix} f^{1\prime} & f^{2\prime} & f^{3\prime} \\ f^{1\prime\prime} & f^{2\prime\prime} & f^{3\prime\prime} \\ f^{1\prime\prime\prime} & f^{2\prime\prime\prime} & f^{3\prime\prime\prime} \end{vmatrix} = 0.$$

Therefore, the condition is necessary. To prove the sufficient condition, we have $= 0$. So the rank of may be $0, 1, 2$.

Case 1: Let rank $= 0$; i.e. all the elements of are zero, i.e.

$$f^{1'}(s) = f^{2'}(s) = f^{3'}(s) = 0$$

or

$$f^{1}(s) = f^{2}(s) = f^{3}(s) = \text{constant}$$

or

$$x^1(s) = k_1; x^2(s) = k_2; x^3(s) = k_3.$$

Thus, the curve $x^i = f^i(s)$ reduces to a point. Therefore, the given curve is a plane curve. (Trivial case).

Case 2: Let the rank of be 1, then any row will be proportional to any other row of , i.e.

$$\frac{f^{1''}}{f^{1'}} = \frac{f^{2''}}{f^{2'}} = \frac{f^{3''}}{f^{3'}}$$

or

$$\log f^{1'} = (s) + c_1 \Rightarrow f^{1'} = e^{(s)+c_1} = a_1 e^{(s)}$$

or

$$x^i = f^i(s) = a_i \int e^{(s)} ds + b_i = a_i (s) + b_i$$

or

$$\frac{x^1 - b_1}{a_1} = \frac{x^2 - b_2}{a_2} = \frac{x^3 - b_3}{a_3} = (s);$$

which is an equation of a line passing through b_i. Hence, the curves is a plane curve.

Case 3: Let the rank of be 2, then at least one of the minors of order two does not vanish. We assume that

$$b_1 = \begin{vmatrix} f^{2'} & f^{3'} \\ f^{2''} & f^{3''} \end{vmatrix}; b_2 = \begin{vmatrix} f^{3'} & f^{1'} \\ f^{3''} & f^{1''} \end{vmatrix}; b_3 = \begin{vmatrix} f^{1'} & f^{2'} \\ f^{1''} & f^{2''} \end{vmatrix}.$$

So, there exists three numbers $b_1; b_2; b_3$ such that

$$b_1 f^{1'}(s) + b_2 f^{2'}(s) + b_3 f^{3'}(s) = 0 \quad \text{(i)}$$

$$b_1 f^{1''}(s) + b_2 f^{2''}(s) + b_3 f^{3''}(s) = 0 \quad \text{(ii)}$$

$$b_1 f^{1'''}(s) + b_2 f^{2'''}(s) + b_3 f^{3'''}(s) = 0. \quad \text{(iii)}$$

Differentiating with respect to s, we get from Eq. (i),

$$b_i f^{i''}(s) + b_i' f^{i'}(s) = 0 \Rightarrow b_i' f^{i'}(s) = 0;\ \text{using Eq. (ii)}.$$

Similarly, differentiate Eq. (ii) with respect to s and using Eq. (iii), we get, $b_i' f^{i''}(s) = 0$. So, there exists a unique solution to the linear equations

$$b_1' f^{1'}(s) + b_2' f^{2'}(s) + b_3' f^{3'}(s) = 0$$

$$b_1' f^{1''}(s) + b_2' f^{2''}(s) + b_3' f^{3''}(s) = 0.$$

Solving, we get

$$\frac{b_1'}{\begin{vmatrix} f^{2'} & f^{3'} \\ f^{2''} & f^{3''} \end{vmatrix}} = \frac{b_2'}{\begin{vmatrix} f^{3'} & f^{1'} \\ f^{3''} & f^{1''} \end{vmatrix}} = \frac{b_3'}{\begin{vmatrix} f^{1'} & f^{2'} \\ f^{1''} & f^{2''} \end{vmatrix}}$$

$$\Rightarrow \frac{b_1'}{b_1} = \frac{b_2'}{b_2} = \frac{b_3'}{b_3} = \lambda'(s);\ \text{say},$$

or

$$\log b_i = \lambda(s) + c_i \Rightarrow b_i = e^{\lambda(s)+c_i} = a_i e^{\lambda(s)}.$$

But $b_i f^{i'} = 0$; from Eq. (i) replacing b_i, we get

$$a_i e^{\lambda(s)} f^{i'} = 0 \Rightarrow a_i f^{i'} = 0;\ \text{as } e^{\lambda(s)} \neq 0$$

or

$$a_1 f^{1'} + a_2 f^{2'} + a_3 f^{3'} = 0$$

or

$$a_1 f^1 + a_2 f^2 + a_3 f^3 + a_0 = 0.$$

Hence, the curve is a plane curve. When the curve is not plane, then it is called skew curve.

EXAMPLE 5.2.1 Determine $\phi(t)$ such that the curve $x^1 = a\cos t;\ x^2 = a\sin t;\ x^3 = \phi(t)$ is a plane curve and what is the nature of the conic?

Solution: Since the given curve is a plane curve, we have

$$\begin{vmatrix} x^{1'} & x^{2'} & x^{3'} \\ x^{1''} & x^{2''} & x^{3''} \\ x^{1'''} & x^{2'''} & x^{3'''} \end{vmatrix} = \begin{vmatrix} -a\sin t & a\cos t & \phi' \\ -a\cos t & -a\sin t & \phi'' \\ a\sin t & -a\cos t & \phi''' \end{vmatrix} = 0$$

or

$$\phi''' + \phi' = 0 \Rightarrow \phi(s) = a^1 + b\cos t + c\sin t.$$

The nature of the curve will be intersected between the cylinder $x^2 + y^2 = a^2$ and the plane $lx + my + nz = k$.

5.3 Twisted Curve

A curve in E^3 which does not lie on a plane is called *twisted* curve. Thus, the twisted curve is not a plane curve.

EXAMPLE 5.3.1 Find the curvature and the torsion of the circular helix

$$r = \quad a\cos\frac{s}{c}; a\sin\frac{s}{c}; \frac{bs}{c} \quad ; \; c = \sqrt{a^2+b^2};$$

where s is arc length.

Solution: By differentiation with respect to the arc length, the tangent vector is given by

$$T = r' = \quad \frac{a}{c}\sin\frac{s}{c}; \frac{a}{c}\cos\frac{s}{c}; \frac{s}{c} \quad :$$

The normal vector N is given by

$$N = r'' = \quad \cos\frac{s}{c}; \quad \sin\frac{s}{c}; 0 \quad \text{as } c = \sqrt{a^2+b^2}:$$

Finally, the binormal vector is given by

$$B = T \quad N = \begin{array}{ccc} i & j & k \\ \frac{a}{c}\sin\frac{s}{c} & \frac{a}{c}\cos\frac{s}{c} & \frac{s}{c} \\ \cos\frac{s}{c} & \sin\frac{s}{c} & 0 \end{array} = \quad \frac{b}{c}\sin\frac{s}{c}; \quad \frac{b}{c}\cos\frac{s}{c}; \frac{a}{c} \quad :$$

Therefore, the curvature and the torsion of the circular helix are given by,

$$= \frac{a}{c^2}\cos^2\frac{s}{c} + \frac{a}{c^2}\sin^2\frac{s}{c} + 0 = \frac{a}{c^2}$$

$$= \frac{b}{c^2}\cos^2\frac{s}{c} + \frac{b}{c^2}\sin^2\frac{s}{c} + 0 = \frac{b}{c^2}:$$

Thus the curvature and the torsion are both constant, and therefore their ratio is constant. The principal normal intersects the axis of the cylinder orthogonally and the tangent and binormal are inclined at constant angles to the fixed direction of the generators.

5.4 Space Curve Theory

In this section we describe the geometry of the space curve. Formulae analogous to those of Frenet also occur in the theory of surfaces. This section contains a set of three remarkable formulas, generally known as *Serret–Frenet formulae*, which characterise, in the small, all essential geometric properties of space curves.

5.4.1 Serret–Frenet Formulae

In this section we will investigate the theory of twisted curves. Let the curve Γ be given by the equation

$$\Gamma : \; x^i = x^i(s); \tag{5.3}$$

where the parameter s measures the arc distance along the curve. As arc length s along a curve remains invariant, we consider s as the parameter to study the geometry of the space curves. The square of the length of the elements of arc of Γ is given by

$$ds^2 = g_{ij}\, dx^i dx^j$$

or

$$1 = g_{ij} \frac{dx^i}{ds}\frac{dx^j}{ds}; \tag{5.4}$$

showing that $\frac{dx^i}{ds}$ is a unit vector. Let P be a given point with co-ordinates (x^i) and Q be a neighbouring point with co-ordinates $(x^i + dx^i)$ on Γ, corresponding to an increment ds in the arc (Figure 5.2). Then the vector $\lim_{Q\to P} \frac{\vec{PQ}}{ds}$ is called the tangent vector and we shall denote it by λ^i: Thus, Eq. (5.4) can be written as

$$1 = g_{ij}\lambda^i\lambda^j; \quad \text{where } \lambda^i = \frac{dx^i}{ds}: \tag{5.5}$$

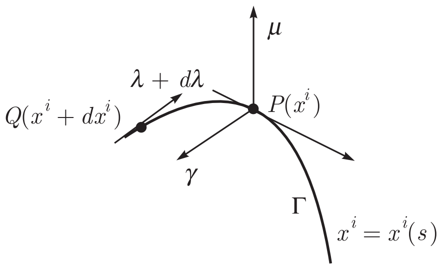

Figure 5.2: Tangent, normal, binormal.

These are precisely the direction cosines of the tangent vector to the curve Γ. We shall assume that curve Γ is of class C^2, so that it has continuously turning tangent at all points of Γ. Taking the intrinsic derivative of Eq. (5.5) with respect to s, we have

$$g_{ij} \frac{\delta\lambda^i}{\delta s}\lambda^j + g_{ij}\lambda^i\frac{\delta\lambda^j}{\delta s} = 0$$

or

$$g_{ij}\;{}^{i}\,\frac{{}^{j}}{s} = 0:$$

Thus, either $\frac{j}{s}$ vanishes or is orthogonal to the tangent vector at some point of a curve, is said to be anormal vector of that curve at that point. Hence, the condition that a vector ^{i} be normal to at P is

$$g_{ij}\;{}^{i}\;{}^{j} = 0: \tag{5.6}$$

Thus, if $\frac{i}{s}$ does not vanish, we denote the unit vector codirectional with $\frac{j}{s}$ by ^{j} and write it as

$${}^{j} = \frac{1}{\ }\frac{{}^{j}}{s}; \tag{5.7}$$

where > 0 is so chosen to make ^{j} a unit vector. The vector ^{i}, determined by Eq. (5.7) is called the principal normal vector to the curve at P and is called the curvature of the curve at that point P. The plane determined by the tangent and the normal is called the osculating plane to the curve at P.

Since is a unit vector, so the quadratic relation

$$g_{ij}\;{}^{i}\;{}^{j} = 1 \tag{5.8}$$

is satisfied. Differentiating Eq. (5.8) intrinsically, we get

$$g_{ij}\,\frac{{}^{i}}{s}\,{}^{j} + g_{ij}\,{}^{i}\,\frac{{}^{j}}{s} = 0 \quad) \quad g_{ij}\,{}^{i}\,\frac{{}^{j}}{s} = 0: \tag{5.9}$$

Taking the intrinsic derivative of the orthogonal relation Eq. (5.5) we get

$$g_{ij}\,\frac{{}^{i}}{s}\,{}^{j} + g_{ij}\,{}^{i}\,\frac{{}^{j}}{s} = 0$$

or

$$\begin{aligned} g_{ij}\,{}^{i}\,\frac{{}^{j}}{s} &= \quad g_{ij}\,\frac{{}^{i}}{s}\,{}^{j} = \quad g_{ij}\;{}^{i}\;{}^{j};\quad \text{from Eq. } (5{:}7)\\ &= \quad ;\quad \text{from Eq. } (5{:}8)\\ &= \quad g_{ij}\;{}^{i}\;{}^{j};\quad \text{from Eq. } (5{:}5) \end{aligned}$$

or

$$g_{ij}\;{}^{i}\quad \frac{{}^{j}}{s} + \quad {}^{j} \quad = 0: \tag{5.10}$$

Also, from Eq. (5.6) we can write $g_{ij}\ {}^{i}\ {}^{j} = 0$; as $g_{ij} = g_{ji}$; i.e.

$$g_{ij}\ {}^{i}\ {}^{j} = 0$$

or

$$g_{ij}\ {}^{i}\frac{{}^{j}}{s} + g_{ij}\ {}^{i}\ {}^{j} = 0$$

or

$$g_{ij}\ {}^{i}\ \frac{{}^{j}}{s} + \ {}^{j} = 0: \qquad (5.11)$$

From Eqs. (5.10) and (5.11) we see that, the vector $\frac{{}^{j}}{s} + \ {}^{j}$ is orthogonal to both the tangent vector ^{i} and the principal normal vector ^{i}: Hence, we choose a vector ^{i} such that

$${}^{i} = \frac{1}{}\ \frac{{}^{i}}{s} + \ {}^{i} \qquad (5.12)$$

and is chosen to make , a unit vector. The constant thus introduced is called the torsion of the curve. Note that, it may be positive or negative in contrast to the curvature which is essentially positive, being the magnitude of a vector.

The sign of is not always positive but we agree to choose the sign of in such a way that (; ;) form a right-hand system, i.e.

$$\varepsilon_{ijk}\ {}^{i}\ {}^{j}\ {}^{k} = +1; \qquad (5.13)$$

where

$$\varepsilon_{ijk} = \sqrt{g}e_{ijk}; \quad \text{and } g = \left|\frac{\partial y^{i}}{\partial x}\right|^{2}; \qquad (5.14)$$

so that the left-hand member of Eq. (5.13) is an invariant. The vector is called the binormal of at P. Also, using Eqs. (5.13) and (5.14), we get

$$\sqrt{g}e_{ijk}\ {}^{i}\ {}^{j}\ {}^{k} = 1$$

or

$$e^{pqr}\sqrt{g}e_{ijk}\ {}^{i}\ {}^{j}\ {}^{k} = e^{pqr}$$

or

$${}^{p}_{i}{}^{q}_{j}{}^{r}_{k}\sqrt{g}\ {}^{i}\ {}^{j}\ {}^{k} = e^{pqr}$$

or

$${}^{p}\ {}^{q}\ {}^{r} = \frac{1}{\sqrt{g}}e^{pqr} = \frac{1}{\sqrt{g}}e^{rpq}$$

or

$$g_{ip}\,{}^{i}g_{jq}\,{}^{j}\;{}^{p}\;{}^{q}\;{}^{r} = g_{ip}\,{}^{i}g_{jq}\,{}^{j}\,\varepsilon^{pqr}; \quad \text{by Eq. } (5{:}14)$$

or

$${}^{r} = \varepsilon^{pqr}\;{}_{p}\;{}_{q} \text{ i.e. } {}^{i} = \varepsilon^{ijk}\;{}_{j}\;{}_{k}. \qquad (5.15)$$

Differentiating Eq. (5.15) intrinsically, we get

$$\frac{{}^{i}}{s} = \varepsilon^{ijk}\frac{{}^{j}}{s}\;{}_{k} + \varepsilon^{ijk}\;{}_{j}\frac{{}^{k}}{s}$$
$$= \varepsilon^{ijk}\;{}_{j}\;{}_{k} + \varepsilon^{ijk}\;{}_{i}[\;{}_{k}\quad{}_{k}];$$

which reduces on account of skew symmetry of ε^{ijk} to

$$\frac{{}^{i}}{s} = \varepsilon^{ijk}\;{}_{j}\;{}_{k}.$$

But ${}_{i}$; ${}_{i}$ and ${}_{i}$ form a right-handed system of unit vectors, so $\varepsilon^{ijk}\;{}_{j}\;{}_{k} = {}^{i}$. Therefore,

$$\frac{{}^{i}}{s} = {}^{i}. \qquad (5.16)$$

Equations (5.7), (5.12) and (5.16) are called the *Frenet formulae* for space curve. On account of their importance in the theory of curves, we group these formulae together for convenient reference in the form

$$\left.\begin{array}{l} \frac{{}^{i}}{s} = {}^{i} \\ \frac{{}^{i}}{s} = {}^{i} + {}^{i} \\ \frac{{}^{i}}{s} = {}^{i} \end{array}\right\}. \qquad (5.17)$$

Equation (5.17) can be written in the matrix form as

$$\frac{}{s}\begin{pmatrix} {}^{i} \\ {}^{i} \\ {}^{i} \end{pmatrix} = \begin{pmatrix} 0 & & 0 \\ & 0 & \\ 0 & & 0 \end{pmatrix}\begin{pmatrix} {}^{i} \\ {}^{i} \\ {}^{i} \end{pmatrix}.$$

The coefficient matrix is skew symmetric. Formulae analogous to those of Frenet also occur in the theory of surfaces.

Note 5.4.1 If the curve lies on a plane, then it is called a *plane curve*, otherwise it is called a *skew curve*.

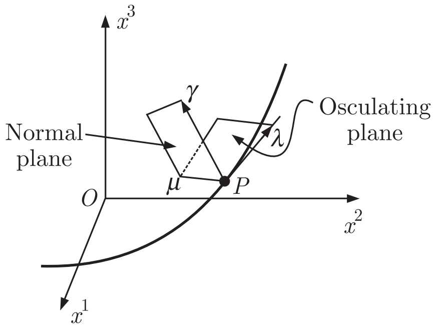

Figure 5.3: Osculating, normal rectifying plane.

Note 5.4.2 The plane determined by the tangent and principal normal is called the osculating plane at a point $P(x^i_0)$ of a space curve (Figure 5.3). It's equation is

$$g_{ij}\ \ x^i\ \ \ x^i_0\ \ \ {}^j = 0;$$

where x^i is any point on the plane. The plane determined by principal normal and binormal is called the normal plane at $P(x^i_0)$ and its equation is given by

$$g_{ij}\ \ x^i\ \ \ x^i_0\ \ \ {}^j = 0:$$

The plane determined by binormal and tangent is called the rectifying plane at $P(x^i_0)$ and its equation is given by (Figure 5.3)

$$g_{ij}\ \ x^i\ \ \ x^i_0\ \ \ {}^j = 0:$$

EXAMPLE 5.4.1 Show that

(i) $= g_{mn}\,\frac{\ \ m}{s}\,\frac{\ \ n}{s}\ {}^{1=2}$

(ii) $= "_{rst}\ \ {}^r\ \ {}^s\frac{\ \ t}{s}$

(iii) ${}_i = \frac{1}{\ }\ \ \frac{\ \ i}{s} + \ \ {}_i$

(iv) ${}_i = "_{ijk}\ \ {}^i\frac{\ \ k}{s}$

(v) ${}_i = \frac{1}{\ }\frac{\ \ i}{s};$

where the symbols have their usual meanings.

Solution:

(i) We know that

$$^{m} = \frac{1}{}\,\frac{{}^{m}}{s}; \quad \frac{{}^{m}}{s} = \quad {}^{m};$$

where > 0 is so chosen to make ^{m} a unit vector. Thus,

$$g_{mn}\frac{{}^{m}}{s}\,{}^{n} = g_{mn}\,{}^{m}\,{}^{n}$$

or

$$g_{mn}\frac{{}^{m}}{s}\,{}^{n} = \quad \text{as}\, g_{mn}\,{}^{m}\,{}^{n} = 1$$

or

$$= g_{mn}\frac{{}^{m}}{s}\frac{1}{}\frac{{}^{n}}{s}$$

or

$$^{2} = g_{mn}\frac{{}^{m}}{s}\frac{{}^{n}}{s}$$

or

$$= \quad g_{mn}\frac{{}^{m}}{s}\frac{{}^{n}}{s}\quad^{1=2}; \quad \text{as} > 0:$$

(ii) From the second Frenet formula we have

$$\frac{{}^{t}}{s} = \quad {}^{t} + \quad {}^{t}$$

or

$$"_{rst}\,{}^{r}\,{}^{s}\frac{{}^{t}}{s} = "_{rst}\,{}^{r}\,{}^{s}\quad{}^{t} + \quad{}^{t}$$

$$= "_{rst}\,{}^{r}\,{}^{s}\,{}^{t} + "_{rst}\,{}^{r}\,{}^{s}\,{}^{t}$$

$$= 0 + \quad {}^{t}\,{}_{t}; \ \text{as}\, "_{rst}\,{}^{r}\,{}^{t} = 0$$

$$= \quad; \ \text{as}\ {}^{t}\,{}_{t} = 1;$$

which is the required result.

(iii) Follows from Eq. (5.12).

(iv) Using relation Eq. (5.17), we get $\frac{{}^{k}}{s} = \quad {}^{k}$, i.e.

$$"_{ijk}\,{}^{j}\frac{{}^{k}}{s} = "_{ijk}\,{}^{j}\quad{}^{k} = "_{ijk}\,{}^{j}\,{}^{k} = \quad{}^{i}; \ \text{from Eq. (5:15):}$$

(v) We see that

$$\frac{1}{}\frac{{}^{i}}{s} = \frac{1}{}\frac{}{s}\; g_{ij} \;{}^{j} = \frac{1}{}g_{ij}\frac{{}^{j}}{s} = \frac{1}{}g_{ij} \;{}^{j} = \;{}_{i}:$$

EXAMPLE 5.4.2 Show that

$$g_{ij}\frac{{}^{i}}{s}\frac{{}^{j}}{s} = \;{}^{2} + \;{}^{2}:$$

Solution: Using Eq. (5.17), we get

$$g_{ij}\frac{{}^{i}}{s}\frac{{}^{j}}{s} = g_{ij} \quad {}^{i} + \quad {}^{i} \qquad {}^{j} + \quad {}^{j}$$

$$= g_{ij} \quad {}^{2}\; {}^{i}\; {}^{j} \qquad {}^{i}\; {}^{j} \qquad {}^{j}\; {}^{i} + \;{}^{2}\; {}^{i}\; {}^{j}$$

$$= \;{}^{2}g_{ij} \; {}^{i}\; {}^{j} \quad g_{ij} \; {}^{i}\; {}^{j} \quad g_{ij} \; {}^{j}\; {}^{i} + \;{}^{2}g_{ij} \; {}^{i}\; {}^{j}$$

$$= \;{}^{2}\; 1 \qquad 0 \qquad 0 + \;{}^{2}\; 1 = \;{}^{2} + \;{}^{2}:$$

EXAMPLE 5.4.3 Show that

(i) $\frac{{}^{2}\;{}^{i}}{s^{2}} = \frac{d}{ds}\;{}^{i} + \qquad {}^{i} \qquad {}^{i}$

(ii) $\frac{{}^{2}\;{}^{i}}{s^{2}} = \frac{d}{ds}\;{}^{i} \quad (\;{}^{2} + \;{}^{2})\;{}^{i} \quad \frac{d}{ds}\;{}^{i}$

(iii) $\frac{{}^{2}\;{}^{r}}{s^{2}} = (\quad {}^{r} \qquad {}^{r}) \quad \frac{d}{ds}\;{}^{r};$

where the symbols have their usual meanings.

Solution:

(i) Using Eq. (5.7), we get, $\frac{{}^{i}}{s} = \;{}^{i}$; where > 0: Differentiating intrinsically with respect to the parameter s we get

$$\frac{{}^{2}\;{}^{i}}{s^{2}} = \frac{}{s} \quad {}^{i} = \frac{d}{ds}\;{}^{i} + \quad {}^{j} \quad \begin{matrix} i \\ j\;\; k \end{matrix} \quad \frac{dx^{k}}{ds}$$

$$= \frac{d}{ds}\;{}^{i} + \frac{d\;{}^{i}}{ds} + \quad {}^{j} \quad \begin{matrix} i \\ j\;\; k \end{matrix} \quad \frac{dx^{k}}{ds}$$

$$= \frac{d}{ds}\;{}^{i} + \quad \frac{d\;{}^{i}}{ds} + \;{}^{j} \quad \begin{matrix} i \\ j\;\; k \end{matrix} \quad \frac{dx^{k}}{ds}$$

$$= \frac{d}{ds}\;{}^{i} + \frac{{}^{i}}{s} = \frac{d}{ds}\;{}^{i} + \qquad {}^{i} + \quad {}^{i} \quad ; \text{ from Eq. } (5{:}17)$$

$$\frac{{}^{2}\;{}^{i}}{s^{2}} = \frac{d}{ds}\;{}^{i} + \qquad {}^{i} \qquad {}^{i} \;;$$

which is the result as required.

(ii) Using Eq. (5.17), we get $\frac{\ {}^{i}}{s} = \ {}^{i} \quad \ {}^{i}$:

$$\frac{{}^{2}\ {}^{i}}{s^2} = \frac{}{s}\ {}^{i} \qquad \frac{}{s}\ {}^{i}$$

$$= \frac{d}{ds}\ {}^{i} + \ {}^{j} \begin{matrix} i \\ j\ k \end{matrix} \frac{dx^k}{ds} \qquad \frac{d}{ds}\ {}^{i} + \ {}^{j} \begin{matrix} i \\ j\ k \end{matrix} \frac{dx^k}{ds}$$

$$= \frac{d}{ds}\ {}^{i} + \frac{d\ {}^{i}}{ds} + \ {}^{j} \begin{matrix} i \\ j\ k \end{matrix} \frac{dx^k}{ds} \qquad \frac{d}{ds}\ {}^{i} \qquad \frac{d\ {}^{i}}{ds} + \ {}^{j} \begin{matrix} i \\ j\ k \end{matrix} \frac{dx^k}{ds}$$

$$= \frac{d}{ds}\ {}^{i} + \frac{\ {}^{i}}{s}\ \frac{d}{ds}\ {}^{i} \qquad \frac{\ {}^{i}}{s}$$

$$= \frac{d}{ds}\ {}^{i} + (\quad {}^{i})\ \frac{d}{ds}\ {}^{i} \qquad {}^{i} = \frac{d}{ds}\ {}^{i} \quad (\ {}^{2} + \ {}^{2})\ {}^{i} \quad \frac{d}{ds}\ {}^{i}:$$

(iii) Using Eq. (5.17), we get $\frac{\ {}^{i}}{s} = \quad {}^{i}$: Differentiating intrinsically with respect to the parameter s we get

$$\frac{{}^{2}\ {}^{i}}{s^2} = \frac{}{s}\ {}^{i} = \frac{d}{ds}\ {}^{i} \qquad {}^{j} \begin{matrix} i \\ j\ k \end{matrix} \frac{dx^k}{ds}$$

$$= \frac{d}{ds}\ {}^{i} \qquad \frac{d\ {}^{i}}{ds} + \ {}^{j} \begin{matrix} i \\ j\ k \end{matrix} \frac{dx^k}{ds}$$

$$= \frac{d}{ds}\ {}^{i} \qquad \frac{\ {}^{i}}{s}$$

$$= \frac{d}{ds}\ {}^{i} \qquad {}^{i} + \quad {}^{i}\ ; \text{ from Eq. } (5{:}17)$$

$$= \quad {}^{i} \quad {}^{i} \quad \frac{d}{ds}\ {}^{i}:$$

EXAMPLE 5.4.4 Show that

$$= \frac{1}{2}"_{ij\ k}\ {}^{i} \frac{\ {}^{i}}{s} \frac{{}^{2}\ {}^{k}}{s^2};$$

where the notations have their usual meaning.

Solution: Using Eq. (5.7), we get $\frac{\ {}^{i}}{s} = \quad {}^{i}$; where, $\ > \ 0$: Differentiating intrinsically with respect to the parameter s we get,

$$\frac{{}^{2}\ {}^{i}}{s^2} = \frac{}{s}\ {}^{i} + \frac{\ {}^{i}}{s} = \frac{}{s}\ {}^{i} + \qquad {}^{i} \qquad {}^{i}\ :$$

Using the Frenet formula [Eq. (5.17)], we get,

$$\frac{1}{2}"_{ijk}\ {}^{i}\frac{{}^{i}}{s}\frac{{}^{2\ \ k}}{s^{2}}$$

$$= \frac{1}{2}"_{ijk}\ {}^{i}\ \ {}^{j}\ \ \frac{}{s}\ {}^{k} + \ \ {}^{k}\ \ \ {}^{k}$$

$$= \frac{1}{}\ \ \frac{}{s}"_{ijk}\ {}^{i}\ {}^{j}\ {}^{k} + \ "_{ijk}\ {}^{i}\ {}^{j}\ {}^{k}\ \ \ {}^{2}"_{ijk}\ {}^{i}\ {}^{j}\ {}^{k}$$

$$= \frac{1}{}(0 + \ \ \ 0) = \ :$$

EXAMPLE 5.4.5 Find the curvature and torsion at any point of a given curve (circle) , given by

$$:\ x^{1} = a; x^{2} = t; x^{3} = 0;$$

where $ds^{2} = \ dx^{1}\ {}^{2} + (x^{1})^{2}\ dx^{2}\ {}^{2} + \ dx^{3}\ {}^{2}:$

Solution: The square of the element of arc in cylindrical co-ordinates as

$$ds^{2} = \ dx^{1}\ {}^{2} + (x^{1})^{2}\ dx^{2}\ {}^{2} + \ dx^{3}\ {}^{2}:$$

For the given metric, the non-vanishing Christoffel symbols are

$$\begin{matrix}1\\2\ 2\end{matrix} = \ x^{1};\quad \begin{matrix}2\\1\ 2\end{matrix} = \begin{matrix}2\\2\ 1\end{matrix} = \frac{1}{x^{1}};$$

and $g_{11} = 1 = g_{33}$ and $g_{22} = (x^{1})^{2} = a^{2}$: The tangent vector ^{i} is given by

$${}^{i} = \frac{dx^{i}}{ds} = \ \frac{dx^{1}}{ds};\frac{dx^{2}}{ds};\frac{dx^{3}}{ds}\ = \ 0;\frac{dt}{ds};0\ :$$

As is a unit vector, so $g_{ij}\ {}^{i}\ {}^{j} = 1$; i.e.

$$g_{11}\ {}^{1}\ {}^{1} + g_{22}\ {}^{2}\ {}^{2} + g_{33}\ {}^{3}\ {}^{3} = 1$$

or

$$a^{2}\ \frac{dt}{ds}\ {}^{2} = 1\ )\ \frac{dt}{ds} = \frac{1}{a}:$$

Therefore

$${}^{i} = \ 0;\frac{dt}{ds};0\ = \ 0;\frac{1}{a};0\ :$$

Now, from the Serret{Frenet formula [Eq. (5.7)], i.e. $^i = \frac{^i}{s}$; we get,

$$^1 = \frac{^1}{s} = \frac{d\ ^1}{ds} + \begin{matrix}1\\ j\ \ k\end{matrix}\ ^j\frac{dx^k}{ds}$$

$$= \frac{d\ ^1}{ds} + \begin{matrix}1\\ 2\ \ 2\end{matrix}\ ^2\frac{dx^2}{ds} = 0 + (\ \ x^1)\frac{1}{a}\frac{dt}{ds} = \ \ \frac{1}{a}:$$

$$^2 = \frac{^2}{s} = \frac{d\ ^2}{ds} + \begin{matrix}2\\ j\ \ k\end{matrix}\ ^j\frac{dx^k}{ds}$$

$$= 0 + \begin{matrix}2\\ 1\ \ 2\end{matrix}\ ^1\frac{dx^2}{ds} + \begin{matrix}2\\ 2\ \ 1\end{matrix}\ ^2\frac{dx^1}{ds}$$

$$= \frac{1}{x^1}0\ \ ^2 + \frac{1}{x^1}\frac{1}{a}\ \ ^1 = 0:$$

Similarly, $^3 = 0$: Since is a unit vector, so,

$$g_{ij}\ \ ^i\ \ ^j = 1;\quad \text{i.e.}\quad g_{11}\ \ ^1\ \ ^1 + g_{22}\ \ ^2\ \ ^2 + g_{33}\ \ ^3\ \ ^3 = 1$$

or

$$1\ \ \frac{1}{a}\ \ \frac{1}{a} + 0 + 0\ \ \ 0\ \ 0 = 1\ )\ \ \ = \frac{1}{a};\ \text{as}\ \ >\ \ 0:$$

Consequently,

$$^1 = \ \ \frac{1}{a}\ )\ \ \ ^1 = \ \ 1:$$

So, $^i = (\ \ 1; 0; 0)$: From Eq. (5.17), we get $\frac{^i}{s} = \ \ \ ^i + \ \ ^i; i = 1; 2; 3$; thus,

$$^1\ \ \ \ ^1 = \frac{^1}{s} = \frac{d\ ^1}{ds} + \begin{matrix}1\\ j\ \ k\end{matrix}\ ^j\frac{dx^k}{ds}$$

$$= 0 + \begin{matrix}1\\ 2\ \ 2\end{matrix}\ \ ^2\ \ ^2 = 0:$$

Therefore, $^1 = \ \ \ ^1 = 0$: Now

$$^2\ \ \ \ ^2 = \frac{^2}{s} = \frac{d\ ^2}{ds} + \begin{matrix}2\\ j\ \ k\end{matrix}\ ^j\frac{dx^k}{ds}$$

$$= 0 + \begin{matrix}2\\ 1\ \ 2\end{matrix}\ \ ^1\ \ ^2 + \begin{matrix}2\\ 2\ \ 1\end{matrix}\ \ ^2\ \ ^1$$

$$= \frac{1}{a}(\ \ 1)\frac{1}{a} + 0 = \ \ \frac{1}{a^2}$$

or

$$^2 = \quad ^2 \quad \frac{1}{a^2} = \frac{1}{a}\frac{1}{a} \quad \frac{1}{a^2} = 0:$$

and

$$^3 \quad\quad ^3 = \frac{\ ^3}{s} = \frac{d\ ^3}{ds} + \genfrac{}{}{0pt}{}{3}{j\ \ k} \quad ^j \frac{dx^k}{ds} = 0:$$

Therefore $^3 =$ ^{3}: Since is a unit binormal vector, so

$$^1 = \quad ^2 = \quad ^3 = 0 \ ) \quad = 0:$$

To determine the component of , using $^i = "^{ijk} \ _j \ _k$ we get

$$^1 = "^{1jk} \ _j \ _k = "^{123} \ _2 \ _3 + "^{132} \ _3 \ _2 = 0$$

$$^2 = "^{2jk} \ _j \ _k = "^{231} \ _3 \ _1 + "^{213} \ _1 \ _3 = 0$$

$$^3 = "^{3jk} \ _j \ _k = "^{312} \ _1 \ _2 + "^{321} \ _2 \ _1$$

$$= "^{321} \ _2 \ _1 = \frac{1}{g} e^{321} \ _2 \ _1; g = a^2:$$

Now, using the relation $_2 = g_{2m} \ ^m$ and $_1 = g_{1m} \ ^m$; we get

$$_2 = g_{2m} \ ^m = g_{22} \ ^2 = a^2 \ \frac{1}{a} = a$$

$$_1 = g_{1m} \ ^m = g_{11} \ ^1 = \quad 1:$$

Thus

$$^3 = \frac{1}{a}(\quad 1)a(\quad 1) = 1:$$

Hence, the component of the binormal $= (0; 0; 1)$.

Deduction 5.4.1 Let x^i are curvilinear co-ordinates and $\genfrac{}{}{0pt}{}{i}{j\ \ k}$ are Christoffel symbols corresponding to the metric tensor of E^3. According to definition (3.38), we have

$$\frac{\ ^i}{s} = \ ^i_{;k} \frac{dx^k}{ds};$$

where the comma (,) notation denotes covariant differentiation with respect to the metric tensor. Hence,

$$\frac{\ ^i}{s} = \frac{\ ^i}{x^k} + \ ^p \genfrac{}{}{0pt}{}{i}{p\ \ k} \frac{dx^k}{ds}$$

$$= \frac{d\ ^i}{ds} + \ ^p \genfrac{}{}{0pt}{}{i}{p\ \ k} \frac{dx^k}{ds} = \frac{d^2x^i}{ds^2} + \genfrac{}{}{0pt}{}{i}{p\ \ k} \frac{dx^k}{ds}\frac{dx^p}{ds}:$$

Thus, the formula $\frac{\ ^i}{s} = \quad ^i$ can be written as

$$\frac{d\ ^i}{ds} + \ ^p \quad \begin{matrix} i \\ j\ \ k \end{matrix} \quad \frac{dx^j}{ds} = \quad ^i$$

or

$$\frac{d^2x^i}{ds^2} + \quad \begin{matrix} i \\ j\ \ k \end{matrix} \quad \frac{dx^j}{ds}\frac{dx^k}{ds} = \quad ^i:$$

Similarly, we have,

$$\frac{\ ^i}{s} = \frac{d\ ^i}{ds} + \quad \begin{matrix} i \\ j\ \ k \end{matrix} \quad \ ^j \frac{dx^k}{ds}$$

and

$$\frac{\ ^i}{s} = \frac{d\ ^i}{ds} + \quad \begin{matrix} i \\ j\ \ k \end{matrix} \quad \ ^j \frac{dx^k}{ds}: \qquad (5.18)$$

These are the Serret{Frenet formulas in curvilinear co-ordinates E^3:

EXAMPLE 5.4.6 Find the equation of the straight line in curvilinear co-ordinate system E^3:

Solution: Let be a straight line in E^3 and (x^i) be the curvilinear co-ordinates of any point on it. Then the direction of the tangent vector of is fixed. Hence,

$$\frac{\ ^i}{s} = 0; \text{ i.e. } \quad ^i = 0:$$

Since $\ ^i$ is not zero, it follows that $= 0$: Hence, from Eq. (5.18) we get

$$\frac{d^2x^i}{ds^2} + \quad \begin{matrix} i \\ j\ \ k \end{matrix} \quad \frac{dx^j}{ds}\frac{dx^k}{ds} = 0:$$

Since this result holds for any point $P(x^i)$ on , it is the equation of in curvilinear co-ordinates E^3:

EXAMPLE 5.4.7 Show that a space curve is a straight line if and only if its curvature is zero at all points of it.

Solution: First, suppose that the curvature $= 0$ at all points of a space curve : Then by the Frenet formula,

$$\frac{\ ^i}{s} = \quad ^i\ ) \quad \frac{\ ^i}{s} = 0$$

for all s. This means that $\ ^i$ is a fixed direction. Hence is a straight line.

Conversely, let be a straight line, then the direction of the tangent vector of is fixed. Hence,

$$\frac{{}^{i}}{s} = 0 \ ) \qquad {}^{i} = 0:$$

Since ^{i} is not zero, it follows that the = 0: From this example, we can say that the curvature of a curve measures how much the curve differ from being a straight line.

EXAMPLE 5.4.8 Prove that a space curve is a plane curve if and only if its torsion is zero at all points of it.

Solution: First, suppose that a space curve is a plane curve. Then the osculating plane at every point is the plane of . Hence, the binormal ^{i} has a fixed direction, so $\frac{{}^{i}}{s} = 0$: Using Frenet formula we have

$$\frac{{}^{i}}{s} = \qquad {}^{i}\ ) \qquad = 0 \text{ as } {}^{i} \neq 0:$$

Next, we suppose that for a space curve , = 0 at every point of it. Then $\frac{{}^{i}}{s} = 0$; which means that the binormal vector ^{i} has a fixed direction. Hence, the curve is a plane curve. From this example, we can say that the torsion of a curve measures how far the curve departs from lying in a plane.

EXAMPLE 5.4.9 If (a ^{r} + b ^{r} + c ^{r}) forms a parallel vector field along , prove that

$$\frac{da}{ds} \quad b = 0; \ \frac{db}{ds} + \ a \quad c = 0; \ \frac{dc}{ds} + \ b = 0;$$

where the notations have their usual meanings.

Solution: Let $A^{r} = a\ {}^{r} + b\ {}^{r} + c\ {}^{r}$: This vector A^{r} forms a parallel vector field along , if,

$$\frac{A^{i}}{s} = A^{i}_{;j}\frac{dx^{j}}{ds} = 0$$

or

$$\frac{}{s}\ \ a\ {}^{i} + b\ {}^{i} + c\ {}^{i} \ \ = 0$$

or

$$\frac{da}{ds}\ {}^{i} + \frac{db}{ds}\ {}^{i} + \frac{dc}{ds}\ {}^{i} + a\frac{{}^{i}}{s} + b\frac{{}^{i}}{s} + c\frac{{}^{i}}{s} = 0$$

or

$$\frac{da}{ds}\ {}^{i} + \frac{db}{ds}\ {}^{i} + \frac{dc}{ds}\ {}^{i} + a\ \ {}^{i} + b\ \ {}^{i}\ \ \ {}^{i} + c(\ \ \ {}^{i}) = 0$$

or

$$\frac{da}{ds} \quad b \quad {}^{i} + \frac{db}{ds} + a \quad c \quad {}^{i} + \frac{dc}{ds} + b \quad {}^{i} = 0:$$

Since ^{i}; ^{i} and ^{i} are arbitrary, we get

$$\frac{da}{ds} \quad b = 0; \frac{db}{ds} + a \quad c = 0; \frac{dc}{ds} + b = 0:$$

Thus the curvature and the torsion are both constant, and therefore their ratio is constant. The principal normal intersects the axis of the cylinder orthogonally an the tangent and binormal are inclined at constant argles to the fixed direction of the generators.

5.5 Bertrand Curves

Saint{Venant proposed and Bertrand solved the problem of finding the curves whose principal normals are also the principal normals of another curve. If the two curves and $\overline{\ }$ given by (Figure 5.4)

$$: \ x^{i} = x^{i}(s) \text{ and } \overline{\ }: \ \overline{x}^{i} = \overline{x}^{i}(s); \tag{5.19}$$

have a common principal normal, at any of their points, the one is called theBertrand of another or one is called theBertrand associate of another.

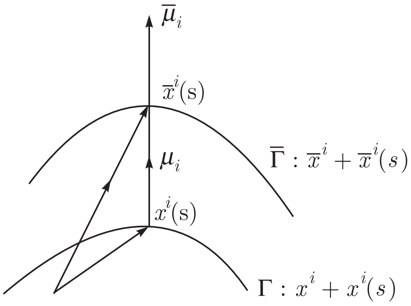

Figure 5.4: Bertrand curve.

EXAMPLE 5.5.1 If is a plane curve, find a curve such that and are Bertrand curves.

Solution: Let E be a plane evolute of , then all involutes of E have the same principal normal as the given curve , because by definition of the involute, these curves intersect orthogonally any tangent to E (Figure 5.5). and any of the curve are therefore Bertrand curves. Moreover, the distance measured along the common principal normal, between corresponding points of any two of these involutes is constant. Two plane curves are therefore called plane parallel curves if they have common principal normals.

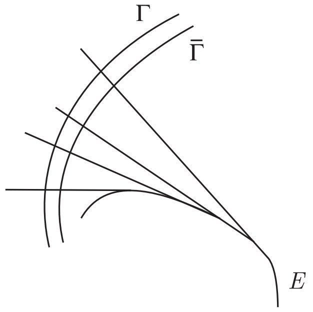

Figure 5.5: Plane curve.

EXAMPLE 5.5.2 Find the necessary and sufficient condition for two curves and are Betrand.

Solution: Let: : $x^i = x^i(s)$ and

$$= x^i = x^i(s) = x^i(s) + a(s) \quad {}^i \qquad (5.20)$$

Differentiating with respect to s intrinsically, we get

$$\frac{\bar{x}^i}{s} = \frac{x^i}{s} + a^1(s) \quad {}^i + a(s)\frac{{}^i}{s}$$

$$= {}^i + a^1(s) \quad {}^i + a(s) \quad {}^i_1 \qquad {}^i$$

or

$$\bar{}^i\frac{d\bar{s}}{ds} = {}^i + a^1(s) \quad {}^i + a(s) \quad {}^i_1 \qquad {}^i \;: \qquad (5.21)$$

Since the two curves are Bertrand, so $\bar{}^i$ is parallel to ^{i}: Taking the inner product of Eq. (5.21) with ^{i} we get

$$\bar{}^i\,\bar{}^i\frac{d\bar{s}}{ds} = {}^i\;{}^i + a^1(s) \quad {}^i\;{}^i + a(s) \quad {}^i_1\;{}^i \qquad {}^i\;{}^i$$

or

$$0 = 0 + a^1(s)1 + a(s)[\quad 0 \qquad 0]\;) \quad a(s) = \text{constant},$$

which is the necessary condition that the two curves are Bertrand curves. Also, from Eq. (5.21), we get

$$\bar{}^i\frac{d\bar{s}}{ds} = {}^i + a(s) \quad {}^i_1 \qquad {}^i = {}^i[1 \quad a \;] + a \quad {}^i:$$

Further, refer to the curve $\bar{}$, we have

$$\frac{d}{ds}(\;{}^i \;\bar{}^i) = \;{}^i\bar{}^i + \;{}^i(-\;{}^i)\frac{d\bar{s}}{ds} = 0 \;) \quad {}^i \;\bar{}^i = \text{constant}.$$

Thus, the tangents to the two curves are inclined at a constant angle. But the principal normals coincide, and therefore, the binormals of the two curves are inclined at the same constant angle. Let be the inclination of $\bar{}^{i}$ to ^{i}, then is constant. If the curve is not plane, i.e. $\neq 0$, then from Eq. (5.21), we get

$$\bar{}^{i} = {}^{i}[1 \quad a\ ]\frac{ds}{d\bar{s}} + a \ {}^{i}\frac{ds}{d\bar{s}}: \tag{5.22}$$

^{i} lies in the plane ^{i} ^{i}, i.e. on the rectifying plane. Moreover, it is obvious from the Figure (5.6) that

$$\bar{}^{i} = \cos \ {}^{i} + \sin \ {}^{i}: \tag{5.23}$$

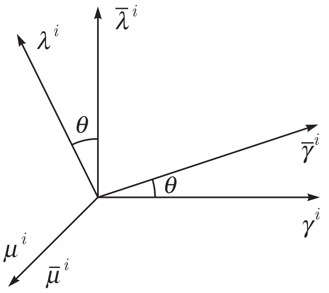

Figure 5.6: The triad.

Comparing Eqs. (5.22) and (5.23), we get

$$\frac{1 \quad a}{\cos} = \frac{a}{\sin} = \frac{d\bar{s}}{ds} \ ) \ 1 \quad a \ = a \ \cot \ : \tag{5.24}$$

Differentiating Eq. (5.23) with respect to s, we get

$$\begin{aligned} \bar{}\frac{d\bar{s}}{ds} &= \sin \ {}^{i}\frac{d}{ds} + \cos \ {}^{i} + \cos \ {}^{i}\frac{d}{ds} \ {}^{i}\sin \\ &= {}^{i}(\ \cos \quad \sin \ ) + \ {}^{i}\cos \quad {}^{i}\sin \ \frac{d}{ds}: \end{aligned}$$

Since the curves are Bertrand curve, so $\bar{}^{i}$ and ^{i} are parallel and equal. Therefore,

$$\begin{aligned} {}^{i}\cos \quad {}^{i}\sin \ \frac{d}{ds} &= 0 \\ ) \ \frac{d}{ds} = 0 \ ) \quad &= \text{constant} \\ ) \ 1 \quad a \ = a \ \cot \ &= b \ (\text{say}); \end{aligned}$$

where b = a cot = constant. Thus, we get a linear equation in and with constant coefficients as a + b = 1: This is the necessary condition that the two curves are Bertrand curves when the curves is not plane.

We shall now show that if X and Y satisfying a + b = 1, where a; b are constants, then is Bertrand of ¯. Differentiating Eq. (5.20) intrinsically with respect to s, we get

$$\bar{}^{i}\frac{d\bar{s}}{ds} = {}^{i}[1 \quad a\ ] + a\ {}^{i} = {}^{i}b + a\ {}^{i}$$

$$= \quad b\ {}^{i} + a\ {}^{i}\ ;\ \text{as}\ a + b = 1$$

or

$$\bar{}^{i} = \quad b\ {}^{i} + a\ {}^{i}\ \frac{ds}{d\bar{s}} = d\ b\ {}^{i} + a\ {}^{i}\ :$$

Since $\bar{}^{i}$ is unit vector, so

$$1 = a^2 d^2 + b^2 d^2 \ )\quad d = \frac{1}{\sqrt{a^2 + b^2}} = \text{constant}:$$

Therefore

$$\bar{}^{i} = p\ {}^{i} + q\ {}^{i};$$

where p and q are constants. Differentiating with respect to s, we get

$$\bar{}\frac{d\bar{s}}{ds} = p\ {}^{i} \quad q\ {}^{i} = {}^{i}(p \quad q\ )$$

$$)\ \bar{}^{i}\ \text{is parallel to}\ {}^{i}\ )\ \bar{}^{i} = {}^{i}:$$

Hence, the curves are Bertrand curves. Thus, the condition is sufficient.

Deduction 5.5.1 If the curve is a plane curve, then = 0 and so

$$\bar{}^{i}\frac{d\bar{s}}{ds} = {}^{i}[1 \quad a\ ]; \tag{5.25}$$

i.e. $\bar{}^{i}$ is parallel to ^{i}. Since $\frac{d\bar{s}}{ds}$ and (1 a) are constants, $\bar{}^{i}$ and ^{i} are both constant vectors and $\bar{}^{i}$ = ^{i}: Differentiating intrinsically, with respect to s, we get,

$$\frac{\bar{x}^{i}}{\bar{s}}\frac{d\bar{s}}{ds} = \frac{{}^{i}}{s}\ )\ \bar{}_{i}\frac{d\bar{s}}{ds} = {}^{i};$$

which shows that $\bar{}^{i}$ is parallel to ^{i}. Thus a = constant is the necessary and sufficient condition that the two curves and ¯ are Bertrand curves, if is a plane curve.

Deduction 5.5.2 There is a linear relation with constant coefficients between the curvature and torsion of . On comparing, we get

$$\cos \ = (1 \quad a\ )\frac{ds}{d\bar{s}};\ \sin \ = a\ \frac{ds}{d\bar{s}}:$$

Now, the relation between the curves and ¯ is clearly a reciprocal one. Hence,

$$\cos = (1 + a)\frac{d\bar{s}}{ds}; \ \sin = a \frac{d\bar{s}}{ds}:$$

On multiplying together of the above equations we obtain the relation

$$\bar{} = \frac{1}{a^2}\sin^2 :$$

This shows that the torsions of the two curves have the same sign, and their product is constant. This theorem is due to Schell. Also,

$$\cos^2 = (1 \quad a)(1 + a)$$

This shows that if $P; P_1$ are corresponding points on the two conjugate Bertrand curves, and $O; O_1$ their centres of curvature, the cross ratio of the range $(P\,OP_1O_1)$ is constant and equal to $\sec^2$. This theorem is due to Mannheim.

5.6 Helix

A space curve traced on the surface of a cylinder, and cutting the generators at a constant angle, is called a helix. Therefore, the tangent vector at every point to a helix makes a constant angle with the fixed direction. Let

$$: \ x^i = x^i(s) \tag{5.26}$$

be an equation of a helix. Let the tangent vector ^{i} to the helix makes a constant angle with a fixed direction a^i (parallel to the generators of the cylinder), where a^i is a unit vector (Figure 5.7). Then,

$$\cos = g_{ij} \ ^i a^j ; 0 < j \ j \quad \frac{1}{2} : \tag{5.27}$$

Differentiating Eq. (5.27) intrinsically with respect to s, we get

$$g_{ij} \frac{\ ^i}{s} a^j = 0$$

or

$$g_{ij} \ ^i a^j = 0; \ \text{as} \ \frac{\ ^i}{s} = \ ^i$$

or

$$g_{ij} \ ^i a^j = 0; \ \text{as} \ > 0:$$

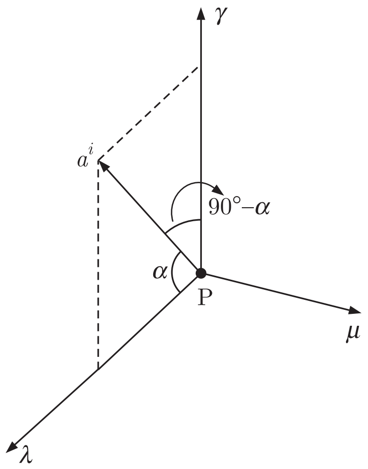

Figure 5.7: Helix.

So, a^i is orthogonal to ^{i}. Thus, since the curvature of the helix does not vanish, the principal normal is everywhere perpendicular to the generators. Hence, the fixed direction of the generators is parallel to the plane of ^{i} and ^{i}; and since it makes a constant angle with ^{i}, it makes a constant angle 90 with ^{i}:

An important property of all helices is that the curvature and torsion are in a constant ratio. Since the angle between a^i and ^{i} is 90 , so,

$$g_{ij}\ {}^i a^j = \cos(90\qquad) = \sin\ : \tag{5.28}$$

Differentiate the relation $g_{ij}\ {}^i a^j = 0$, we get

$$g_{ij}\qquad {}^i\qquad {}^i\ a^i = 0\,:$$

Thus, ^{i} is perpendicular to ^{i} ^{i}. Since a^i must lie in the plane of ^{i} and ^{i}, we can find scalars a and b such that

$$a^i = a\ {}^i + b\ {}^i \tag{5.29}$$

or

$$g_{ij}\ a^i\ {}^j = a g_{ij}\ {}^i\ {}^j + b g_j\ {}^i\ {}^j$$

or

$$\cos\quad = a;\ \text{as}\ g_{ij}\ {}^i\ {}^j = 1 \text{ and } g_{ij}\ {}^i\ {}^j = 0\,:$$

Similarly, from Eq. (5.29) we get,

$$g_{ij}\ a^i\ {}^j = a g_{ij}\ {}^i\ {}^j + b g_j\ {}^i\ {}^j$$

or

$$\sin\quad = b;\ \text{as}\ g_{ij}\ {}^i\ {}^j = 0 \text{ and } g_{ij}\ {}^i\ {}^j = 1\,:$$

Thus, Eq. (5.29) can be written as

$$a^i = {}^i\cos + {}^i\sin : \qquad (5.30)$$

Differentiating Eq. (5.30) intrinsically with respect to s we get

$$\frac{a^i}{s} = \frac{a^i}{s}\cos + \frac{a^i}{s}\sin \ ; \text{ as } = \text{ constant}$$

or

$$0 = {}^i\cos \quad {}^i\sin$$

or

$$\cos \quad \sin = 0; \text{ as } {}^i \neq 0:$$

or

$$- = \tan = \text{ constant.}$$

But a^i is parallel to the plane of ^{i} and ^{i}, and must therefore be parallel to the vector ${}^i +$ ^{i}, which is inclined to ^{i} at an angle $\tan^{1}-$: But this angle is constant. Therefore, the curvature and torsion are in a constant ratio.

Conversely, we may prove that a curve whose curvature and torsion are in a constant ratio is a helix. We suppose that for a space curve different from a straight line $-$ is a constant, i.e. $= c \ ; c =$ constant. Then using Frenet formula we get

$$\frac{{}^i}{s} = c\,{}^i = c\,{}^i = c\frac{{}^i}{s}$$

or

$$\frac{}{s}\ {}^i + c\,{}^i = 0:$$

Therefore, ${}^i + c\,{}^i$ is a constant vector, say a^i. Now,

$$g_{ij}\,a^i\,{}^j = g_{ij}\ {}^i + c\,{}^i\ {}^j$$

$$= g_{ij}\,{}^i\,{}^j + c g_{ij}\,{}^i\,{}^j = 0 + c = c:$$

This shows that the tangent vector ^{i} makes a constant angle with a fixed direction a^i, and the curve is therefore a general helix.

5.6.1 Cylindrical Helix

The cylindrical helix is a curve upon a cylinder which cuts the generator of the cylinder at a constant angle with a fixed direction. Let us take z axis (x^3) as the axis of the cylindrical. Then the equation of the cylinder

$$x^i = {}^i(t);\ i = 1;2:$$

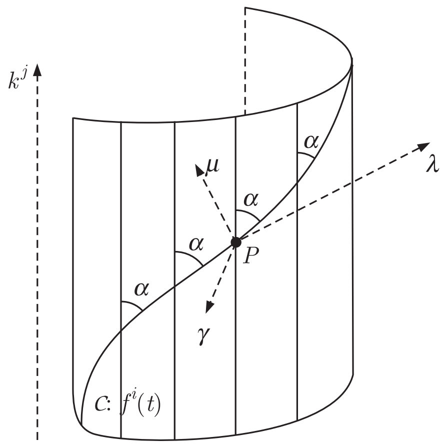

Figure 5.8: Cylindrical helix.

Any curve on the cylinder can be defined by C: $x^i = f^i(t)$; $i = 1, 2, 3$ (Figure 5.8). Let α be the angle at any point P on the curve made by the tangent at P and the generator of this cylinder passing through P. Let the unit vector along the generator is

$$\vec{k} = (0, 0, 1) = (k^1, k^2, k^3)$$

and the unit tangent to the curve at P is

$$\lambda^i = \frac{dx^i}{ds} = \frac{dx^i/dt}{ds/dt} = \frac{dx^i/dt}{|dx^i/dt|}$$

$$= \frac{\dot{f}^1(t), \dot{f}^2(t), \dot{f}^3(t)}{[\{\dot{f}^1(t)\}^2 + \{\dot{f}^2(t)\}^2 + \{\dot{f}^3(t)\}^2]^{1/2}}.$$

Hence, by given condition of the helix,

$$\cos\alpha = g_{ij}\lambda^i k^j = \frac{\dot{f}^3(t)}{\left[\{\dot{f}^1(t)\}^2 + \{\dot{f}^2(t)\}^2 + \{\dot{f}^3(t)\}^2\right]^{1/2}}$$

or

$$\{\dot{f}^3(t)\}^2 = \cos^2\alpha \left[\{\dot{f}^1(t)\}^2 + \{\dot{f}^2(t)\}^2 + \{\dot{f}^3(t)\}^2\right]$$

or

$$\{\dot{f}^3(t)\}^2 \sin^2\alpha = \cos^2\alpha \left[\{\dot{f}^1(t)\}^2 + \{\dot{f}^2(t)\}^2\right]$$

or

$$\dot{f}^3(t) = \cot\alpha \left[\{\dot{f}^1(t)\}^2 + \{\dot{f}^2(t)\}^2\right]^{1/2}$$

or

$$f^3(t) = \cot \int \left[\{\dot f^1(t)\}^2 + \{\dot f^2(t)\}^2 \right]^{1/2} + \text{constant}$$

or

$$f^3(t) = x^3(t) = \cot \int \{\dot x^1\}^2 + \{\dot x^2\}^2{}^{1/2} + \text{constant}:$$

Therefore, the equation of the cylindrical helix can be written as

$$\left.\begin{aligned} &x^1 = f^1(t);\ x^2 = f^2(t) \\ &x^3 = f^3(t) = \cot \int \{\dot x^1\}^2 + \{\dot x^2\}^2{}^{1/2} + \text{constant}: \end{aligned}\right\} \tag{5.31}$$

5.6.2 Circular Helix

If a space curve lies on a circular cylinder and the tangent at each point of it makes a constant angle with the axis of the cylinder, then the curve is a helix. Such a helix is called a circular helix. Thus, a particular case of the cylindrical helix is circular helix, which can be defined by $x^1 = a\cos t$ and $x^2 = a\sin t$. Hence, by Eq. (5.33), we get

$$\begin{aligned} x^3( ) &= \cot \int_0^t \sqrt{a^2(\cos^2 t + \sin^2 t)}\, d \\ &= a\cot\ t = bt;\ \text{where } b = a\cot\ = \text{constant.} \end{aligned}$$

Thus, the parametric equation of the circular helix can be written as

$$C : x^1 = a\cos t;\quad x^2 = a\sin t;\quad x^3 = bt;\quad b \neq 0: \tag{5.32}$$

This curve [Eq. (5.32)] can be defined by giving a constant rotation about the axis of the cylinder and a constant translation about the same axis (Figure 5.9).

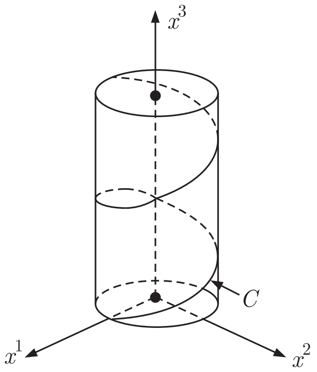

Figure 5.9: Circular Helix.

The circular helix is a twisted curve. The orthogonal projection of the helix into the x^1x^2-plane is the circle

$$(x^1)^2 + (x^2)^2 - a^2 = 0;\ x^3 = 0;$$

which is the intersection of this plane with the cylinder of revolution on which the helix lies. Projecting the helix orthogonally into the x^1x^3-plane, we obtain the sine curve

$$x^2 - a\sin\frac{x^3}{b} = 0;\ x^1 = 0.$$

A cosine curve is obtained by projecting the helix orthogonally into the x^1x^3-plane. Now

$$\frac{d\vec{r}}{dt} = (-a\sin t;\ a\cos t;\ b).$$

Therefore the arc $s(t)$ is given by

$$s(t) = \int_0^t \left(\frac{d\vec{r}}{dt}\cdot\frac{d\vec{r}}{dt}\right)^{1/2} dt = \int_0^t (a^2+b^2)^{1/2}dt$$
$$= \sqrt{a^2+b^2}\ t = wt; \quad \text{where } w = \sqrt{a^2+b^2}.$$

Thus the parametric representation of the circular helix with s as parameter is given by

$$\vec{r} = \left(a\cos\frac{s}{w};\ a\sin\frac{s}{w};\ \frac{b}{w}\right);\quad w = \sqrt{a^2+b^2}.$$

The unit tangent vector to this curve is of the form

$$\vec{t} = \frac{d\vec{r}}{ds} = \left(-\frac{a}{w}\sin t;\ \frac{a}{w}\cos t;\ \frac{b}{w}\right);\quad w = \sqrt{a^2+b^2}.$$

The osculating plane of the circular helix can be represented in the form

$$\begin{vmatrix} z_1 - a\cos t & -a\sin t & -a\cos t \\ z_2 - a\sin t & a\cos t & -a\sin t \\ z_3 - bt & b & 0 \end{vmatrix} = 0$$

which is equivalent to

$$z_1 b\sin t - z_2 b\cos t + (z_3 - bt)a = 0$$

The osculating plane passes through the tangent to the helix and passes through the straight line $\vec{z}(e) = (c\cos t;\ c\sin t;\ bt)$ where t is fixed and c is a real parameter. This line is parallel to x^1x^2-plane. It passes through the axis of the cylinder on which the helix lies as well as through a point P of the helix. Moreover, it is orthogonal to the tangent to the helix at P. Now the curvature and torsion of the circular helix are

$$= \frac{d\bar{r}}{ds} = \sqrt{\frac{d^2\bar{r}}{ds^2}\,\frac{d^2\bar{r}}{ds^2}} = \frac{a}{a^2+b^2}$$

$$= \frac{\left[\frac{d\bar{r}}{ds}; \frac{d^2\bar{r}}{ds^2}; \frac{d^3\bar{r}}{ds^3}\right]}{\frac{d\bar{r}}{ds}\,\frac{d\bar{r}}{ds}\quad\frac{d^2\bar{r}}{ds^2}\,\frac{d^2\bar{r}}{ds^2}\quad\frac{d\bar{r}}{ds}\,\frac{d^2\bar{r}}{ds^2}^{\,2}} = \frac{b}{a^2+b^2}.$$

The circular helix $r = (a\cos t; a\sin t; bt)$ is said to be right-handed (Figure 5.10) if $b > 0$, where the curvature $k = \frac{a}{a^2+b^2}$. As the torsion $= \frac{b}{a^2+b^2}$ so the curve is right-handed when > 0.

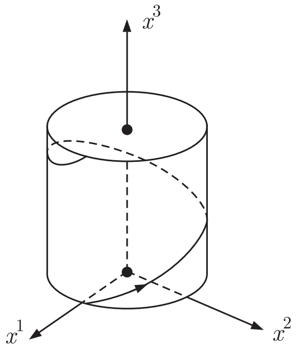

Figure 5.10: Circular Helix > 0.

Similarly, the circular helix $r = (a\cos t; a\sin t; bt)$ is said to be left-handed if $b < 0$, that is < 0 (Figure 5.11).

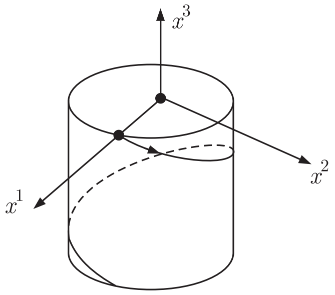

Figure 5.11: Circular Helix < 0.

If b tends to 0, the radius of curvature $= \frac{1}{}$ tends to the radius a of the circle of intersection between x^1x^2-plane and the cylinder of revolution on which the helix lies.

EXAMPLE 5.6.1 Prove that

$$"_{ijk} \frac{i}{s} \frac{2\ j}{s^2} \frac{3\ k}{s^3} = {}^5 \frac{d}{ds} \quad - :$$

Hence, a curve is a helix if and only if

Solution: Using Eq. (5.7), we get

$$"_{ijk} \frac{i}{s} \frac{2\ j}{s^2} \frac{3\ k}{s^3} = 0 :$$

$$\frac{i}{s} = {}^i; \text{ where } > 0:$$

Differentiating intrinsically with respect to the parameter s we get

$$\frac{2\ i}{s^2} = \frac{}{s}\ {}^i + \frac{i}{s} = \frac{}{s}\ {}^i + \quad {}^i \quad {}^i :$$

$$\frac{3\ i}{s^3} = \frac{2}{s^2}\ {}^i + \frac{}{s}\frac{i}{s} + \frac{}{s} \quad {}^i$$

$$+ \frac{}{s}\ {}^i + \frac{i}{s} \quad 2\frac{}{s} \quad {}^i \quad {}^2\frac{i}{s}$$

$$= \frac{2}{s^2}\ {}^i + \frac{}{s} \quad {}^i \quad {}^i + \frac{}{s} + \frac{}{s} \quad {}^i$$

$$+ \quad {}^i \quad 2\frac{}{s} \quad {}^i \quad {}^2 \quad {}^i$$

$$= \frac{2}{s^2} \quad {}^2 \quad {}^3 \quad {}^i + 2\frac{}{s} + \frac{}{s} \quad {}^i + 3\frac{}{s} \quad {}^i :$$

Therefore the given expression becomes,

$$"_{ijk} \frac{i}{s} \frac{2\ j}{s^2} \frac{3\ k}{s^3}$$

$$= "_{ijk} \quad {}^i \frac{}{s}\ {}^j + \quad {}^j \quad {}^j \quad \frac{2}{s^2} \quad {}^2 \quad {}^3 \quad {}^k$$

$$+ 2\frac{}{s} + \frac{}{s}\ {}^k + 3\frac{}{s} \quad {}^k$$

$$= \frac{}{s}"_{ijk} \quad {}^i\ {}^j + {}^2\ "_{ijk} \quad {}^i\ {}^j \quad 3"_{ijk} \quad {}^i\ {}^j$$

$$\frac{2}{s^2} \quad {}^2 \quad {}^3 \quad {}^k + 2\frac{}{s} + \frac{}{s}\ {}^k + 3\frac{}{s} \quad {}^k$$

$$= 0 + {}^2\ {}^k + {}^3\ {}^k \quad \frac{2}{s^2} \quad {}^2 \quad {}^3 \quad {}^k + 2\frac{}{s} + \frac{}{s} \quad {}^k$$

$$+ 3\frac{}{s} \quad {}^k$$

$$= \frac{2}{s^2} \quad 2 \quad 3 \quad 2 \quad k \; k + 3 \; k \; k + 2\frac{}{s} + \frac{}{s}$$

$$2 \quad k \; k + 3 \; k \; k \quad 3 \frac{}{s} \quad 2 \quad k \; k + 3 \; k \; k$$

$$= {}^{3} \; 2\frac{}{s} + \frac{}{s} \quad 3 \frac{}{s}({}^{2})$$

$$= {}^{3} \frac{}{s} \quad 3 \frac{}{s} = {}^{5}\frac{1}{2} \frac{}{s} \quad 3 \frac{}{s} = {}^{5}\frac{d}{ds} \; - :$$

Thus the result is established. Now,

$$"_{ijk} \frac{i}{s} \frac{2 \; j}{s^2} \frac{3 \; k}{s^3} = 0$$

or

$$^{i} + \quad ^{i} \quad ^{i}(\; ^{2} + \; ^{2}) = 0$$

or

$$^{i} + \quad ^{i} = 0; \text{ as } \; ^{2} + \; ^{2} \neq 0 \text{ and } \; ^{i} \text{ is arbitrary}$$

or

$$g_{ij} \quad ^{i} + \quad ^{i} = 0 :$$

If a^i is the fixed direction, then by hypothesis $g_{ij}\, a^i \; ^j = \cos$ and $g_{ij}\, a^i \; ^j = \sin$: Therefore,

$$g_{ij}\, a^i \quad ^{i} + \quad ^{i} = 0$$

or

$$\cos \; + \; \sin \; = 0$$

or

$$- = \; \tan \; = \text{ constant.}$$

Hence, the curve is a helix.

EXAMPLE 5.6.2 Prove that a circular helix is a Bertrand curve.

Solution: We know the circular helix is a twisted curve. The principal normals to a circular helix intersect the axis of rotation of the cylinder Z on which lies at right angles. The points of intersection of these normals with any cylinder $\bar{Z}$, coaxial with Z, determine a circular helix $\bar{}$ (Figure 5.12). Obviously and $\bar{}$ are Bertrand curves, and there exist infinitely many helices $\bar{}$ of this type which, together with , are Bertrand curves.

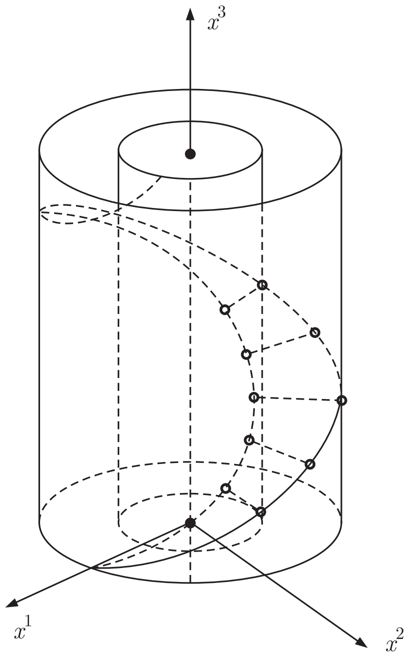

Figure 5.12: Coaxial circular helices < 0.

If two curves : $x^i(s)$; $k > 0$ and $\bar{}$: $\bar{x}^i(s)$ are Bertrand curves then, $\bar{}$ can be represented in the form

$$x^i(s) = x^i(s) + a(s)\ {}^i(s)$$

where ${}^i(s)$ is the unit principal normal vector to and the scalar $a(s)$ is the distance of a point P of $\bar{}$ from the corresponding point P of . Now $a(s)$ is constant, that is, is dependent of S. Hence the circular helix is a Bertrand curve.

EXAMPLE 5.6.3 If the tangent and binormal to a space curve make angles and with a xed direction, show that

$$- = \frac{\sin}{\sin}\frac{d}{d}:$$

Solution: Let the tangent vector with components ^{i} to a space curve C make an angle with a xed direction c^i, where the vector with components c^i is a unit vector and the binormal ^{i} makes an angle with c^i. Then,

$$g_{ij}\ {}^i c^j = \cos \quad \text{and}\ g_{ij}\ {}^i c^j = \cos\ :$$

Since and are invariants,

$$\frac{}{s} = \frac{d}{ds} \text{ and } \frac{}{s} = \frac{d}{ds}:$$

Taking intrinsic derivative of both the sides of the equation $g_{ij}\ ^{i}c^{j} = \cos$, we get

$$g_{ij}\quad ^{i}\ c^{j} = \frac{\ }{s}\cos\ = \frac{d}{ds}(\cos\ )$$

or

$$g_{ij}\ ^{i}c^{j} = \quad \sin\ \frac{d}{ds}:$$

Similarly, from the relation $g_{ij}\ ^{i}c^{j} = \cos$, we get

$$g_{ij}\ ^{i}c^{j} = \quad \sin\ \frac{d}{ds}:$$

Combining these two results, we get

$$\frac{\ }{\ } = \quad \frac{\sin}{\sin}\frac{d}{d}:$$

EXAMPLE 5.6.4 A curve is defined in cylindrical co-ordinates x^i as follows:

$$x^1 = a;\ x^2 = t;\ x^3 = bt;\ b \neq 0$$

where a and b are constants of which a is positive and t is a function of the natural parameter s. Find the curvature and torsion of .

Solution: The components of the tangent vector ^{i} are given by

$$^1 = \frac{dx^1}{ds} = 0;\quad ^2 = \frac{dx^2}{ds} = \frac{dt}{ds};\quad ^3 = \frac{dx^3}{ds} = b\frac{dt}{ds}:$$

Since $g_{ij}\ ^{i}\ ^{j} = 1$, we get

$$g_{11}\ ^{1}\ ^{1} + g_{22}\ ^{2}\ ^{2} + g_{33}\ ^{3}\ ^{3} = 1$$

or

$$0 + \ {x^1}^{2}\ {\frac{dt}{ds}}^{2} + b^2\ {\frac{dt}{ds}}^{2} = 1$$

or

$$(a^2 + b^2)\ {\frac{dt}{ds}}^{2} = 1\ )\quad {\frac{dt}{ds}}^{2} = \frac{1}{a^2 + b^2}:$$

From the relation

$$^i = \frac{d\ ^i}{ds} + \ \begin{matrix} i \\ j\ \ k \end{matrix}\ \ ^j\frac{dx^k}{ds};$$

we get

$$^{1} = \frac{d\ ^{1}}{ds} + \begin{matrix}1\\ 2\ \ 2\end{matrix}\ ^{2}\frac{dx^{2}}{ds} = \ x^{1}\ \frac{dt}{ds}\ ^{2} = \frac{a}{a^{2}+b^{2}}$$

$$^{2} = \frac{d\ ^{2}}{ds} + \begin{matrix}2\\ 2\ \ 1\end{matrix}\ ^{2}\frac{dx^{1}}{ds} + \begin{matrix}2\\ 1\ \ 2\end{matrix}\ ^{1}\frac{dx^{2}}{ds} = 0$$

$$^{3} = 0:$$

Using $g_{ij}\ ^{i}\ ^{j} = 1$, we get

$$g_{11}\ ^{1}\ ^{1} + g_{22}\ ^{2}\ ^{2} + g_{33}\ ^{3}\ ^{3} = 1$$

or

$$\frac{a}{(a^{2}+b^{2})}:\ \ \frac{a}{(a^{2}+b^{2})} = 1\ )\ \ = \frac{a}{a^{2}+b^{2}}:$$

So $^{1} = \ 1;\ \ ^{2} = 0;$ and $^{3} = 0:$ From the relation

$$\frac{d\ ^{i}}{ds} + \begin{matrix}i\\ j\ \ k\end{matrix}\ ^{j}\frac{dx^{k}}{ds} = \ ^{i} + \ ^{i};$$

we get

$$\frac{d\ ^{1}}{ds} + \begin{matrix}1\\ 2\ \ 2\end{matrix}\ ^{2}\frac{dx^{2}}{ds} = \ ^{1} + \ ^{2}$$

or

$$0 + 0 = \ ^{1}\ )\ \ ^{1} = 0:$$

Similarly, $^{2} = \frac{b^{2}}{a(a^{2}+b^{2})^{3=2}}$ and $^{3} = \frac{ab}{(a^{2}+b^{2})^{3=2}}:$ Using $g_{ij}\ ^{i}\ ^{j} = 1$, we get

$$g_{11}\ ^{1}\ ^{1} + g_{22}\ ^{2}\ ^{2} + g_{33}\ ^{3}\ ^{3} = 1$$

or

$$0 + a^{2}\frac{b^{2}}{a(a^{2}+b^{2})^{3=2}}\ \ \frac{b^{2}}{a(a^{2}+b^{2})^{3=2}} + \frac{ab}{(a^{2}+b^{2})^{3=2}}\ \ \frac{ab}{(a^{2}+b^{2})^{3=2}} = 1$$

or

$$^{2} = \frac{b^{2}(a^{2}+b^{2})}{(a^{2}+b^{2})^{3}} = \frac{b^{2}}{(a^{2}+b^{2})^{2}}\ )\ \ = \frac{b}{a^{2}+b^{2}}:$$

Thus, for the given helix, both the curvature and the torsion are constants. Next, we shall show that and are constants, thus, there exists a unique circular helix. Let $= l$ and $= m$ be constants. Choose

$$l = \frac{a}{a^{2}+b^{2}}\ \text{ and }\ m = \frac{b}{a^{2}+b^{2}};$$

where a and b are constants. Therefore,

$$\frac{l}{a} = \frac{m}{b} = \frac{1}{a^2 + b^2}) \quad a = l(a^2 + b^2);\ b = m(a^2 + b^2):$$

Also

$$l^2 + m^2 = \frac{a^2 + b^2}{(a^2 + b^2)^2} = \frac{1}{a^2 + b^2}$$

So

$$\frac{a}{l} = \frac{b}{m} = a^2 + b^2 = \frac{1}{l^2 + m^2}:$$

Let us form a curve

$$:\ x^i(t) = \frac{l}{l^2 + m^2}\cos t;\ \frac{m}{l^2 + m^2}\sin t;\ \frac{m}{l^2 + m^2}t \quad ;$$

which will satisfy all the necessary conditions for a circular helix.

5.7 Spherical Indicatrix

The locus of a point, whose position vector is equal to unit tangent ^{i} of a given curve, is called the spherical indicatrix of the tangent to the curve. Such a locus lies on the surface of a unit sphere; hence the name. Let the two curves and $\bar{}$ be given by

$$:\ x^i = x^i(s) \text{ and } \bar{}:\ \bar{x}^i = \bar{x}^i(s):$$

of class 2 with non-vanishing curvature. We assume that the tangent principal normal and the binormal vectors undergo a parallel displacement (Figure 5.13) and become bound at the origion O is space. Then the terminal points of these vectors (s); (s) are (s) lie on a unit sphere S with centre O and generate, is general, three curves on S which are called tangent indicatrix, the principal normal indicatrix and the binormal indicatrix, respectively, of the curve .

Thus, according to the definition of tangent indicatrix, $\bar{x}^i(s) = {}^i$; therefore,

$$\bar{}^i = \frac{d\bar{x}^i}{d\bar{s}} = \frac{d\ {}^i}{ds}\frac{ds}{d\bar{s}} = \quad {}^i\frac{ds}{d\bar{s}}$$

showing that the tangent to the spherical indicatrix is parallel to the principal normal at the corresponding point of the given curve.

The linear element $d\bar{s}_1; d\bar{s}_N$ and $d\bar{s}_B$ of these indicatrices or spherical images can be obtained by means of Eq. (5.17) for the Serret-Frenet formula. Since (s); (s) and

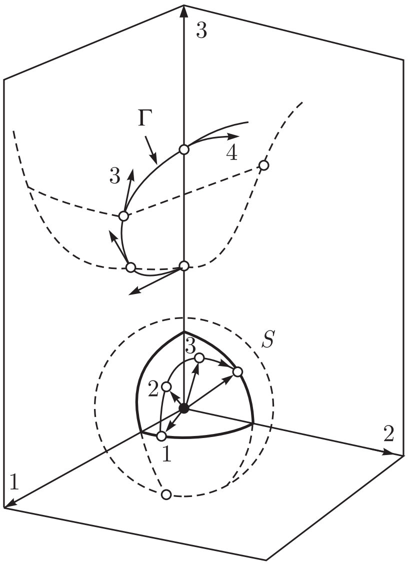

Figure 5.13: Curve and corresponding tangent indicatrix.

(s) are the vector functions representing these curves we find

$$ds_T^2 = \frac{d\ ^i}{ds}\frac{d\ ^j}{ds}ds^2 = k^2\ \ ^i\ \ ^j ds^2 = k^2 ds^2$$

$$ds_N^2 = \frac{d\ ^i}{ds}\frac{d\ ^j}{ds}ds^2 = (\ \ k\ \ ^i + \ \ ^i)(\ \ k\ \ ^i + \ \ ^i)ds^2 = (\ k^2 + \ \ ^2)ds^2$$

$$ds_B^2 = \frac{d\ ^i}{ds}\frac{d\ ^i}{ds}ds^2 = (\ \ ^i)(\ \ ^j)ds^2 = \ \ ^2 ds^2:$$

Moreover we obtain the Equation of Lancret $ds_N^2 = ds_T^2 + ds_B^2$. The expression $\sqrt{ds_T^2 + ds_B^2}$ is sometimes called the third and total curvature of a curve.

We may measure $\bar{s}$ so that $\bar{\ }^i = \ ^i$ and therefore $\frac{d\bar{s}}{ds} = \ $: For the curvature $\bar{\ }$ of the indicatrix, on differentiating the relation $\bar{\ }^i = \ ^i$, we find the formula

$$\bar{\ \ }^i = \frac{d\ ^i}{ds}\frac{ds}{d\bar{s}} = \frac{1}{\ }(\ \ \ ^i\ \ \ \ ^i):$$

Squaring both sides we obtain the result

$$\bar{\ }^2 = \frac{1}{\ ^2}(\ \ ^2 + \ \ ^2);$$

so that the curvature of the indicatrix is the ratio of the screw curvature to the circular curvature of the curve. The unit binormal of the indicatrix is

$$\bar{\ }^i = \text{"}^{ijk}\ \ _j\ \ _k = \frac{1}{\ }(\ \ ^i + \ \ ^i):$$

Using the result

$$"_{ijk}\,\frac{\ \ i}{s}\,\frac{2\ \ j}{s^2}\,\frac{3\ \ k}{s^3} = {}^3\quad\frac{}{s}\quad\frac{}{s}$$

the torsion can be obtained as

$$\overline{\ }^2\ \frac{d\bar{s}}{ds}^{6} = "_{ijk}\,\frac{\ \ i}{s}\,\frac{2\ \ j}{s^2}\,\frac{3\ \ k}{s^3} = {}^3\quad\frac{}{s}\quad\frac{}{s}$$

$$)\ \ \bar{} = \frac{1}{(\ ^2+\ ^2)}\quad\frac{}{s}\quad\frac{}{s}\ :$$

Similarly, the spherical indicatrix of the binormal of the given curve is the locus of a point whose position vector is $\bar{x}^i = {}^i$: Therefore,

$$\bar{}^i = \frac{d\ ^i}{ds}\frac{ds}{d\bar{s}} = \ {}^i\frac{ds}{d\bar{s}}:$$

We may measure $\bar{s}$ so that $\bar{}^i = {}^i$; and therefore $\frac{d\bar{s}}{ds} =$: To find the curvature differentiate the equation $\bar{}^i = {}^i$; we get

$$\bar{}'^i = \frac{d}{ds}(\ ^i)\frac{ds}{d\bar{s}} = \frac{1}{}(\ ^i\quad ^i);$$

giving the direction of the principal normal. On squaring this result we get

$$\bar{}^2 = \frac{1}{^2}(\ ^2+\ ^2):$$

Thus, the curvature of the indicatrix is the ratio of the screw curvature to the torsion of the given curve. The unit binormal is

$$\bar{}^i = \frac{1}{\bar{}}(\ ^i+\ ^i)$$

and the torsion, found as in the previous case, is equal to

$$\bar{} = \frac{1}{(\ ^2+\ ^2)}\quad\frac{}{s}+\frac{}{s}\ :$$

Different curves may have the same spherical images. Simple examples illustrating this fact are circles in the same plane, with arbitrary radius and centre, and also circular helices on coaxial cylinders (Figure 5.12) for which the ratio $a : b$ is the same.

5.8 Exercises

1. If the principal normal of a space curve vanishes identically, show that its equation in curvilinear co-ordinates x^i is given by

$$\frac{d^2x^i}{ds^2} + \begin{matrix} i \\ j \ \ k \end{matrix} \ \frac{dx^j}{ds}\frac{dx^k}{ds} = 0:$$

2. If $"^{ijk}$ is the covariant permutation tensor, show that
   (i) $"^{ijk} \ {}_i \ {}_j = \ {}^k = \ "^{ijk} \ {}_i \ {}_j$
   (ii) $"^{ijk} \ {}_i \ {}_j = \ {}^k = \ "^{ijk} \ {}_i \ {}_j$
   (iii) $"^{ijk} \ {}_i \ {}_j = \ {}^k = \ "^{ijk} \ {}_i \ {}_j:$

3. Show that
   (i) $g_{ij} \frac{i}{s}\frac{j}{s} =$
   (ii) $g_{ij} \frac{i}{s}\frac{j}{s} = \ {}^2 + \ {}^2$
   (iii) $g_{ij} \frac{i}{s}\frac{j}{s} = \ {}^2;$
   (iv) $g_{ij} \frac{i}{s}\frac{j}{s} = 0.$

4. Prove that,

$$"_{ijk} \frac{i}{s}\frac{2 \ j}{s^2}\frac{3 \ k}{s^3} = \ {}^5\frac{d}{ds} \quad - \ :$$

5. Prove that
   (i) $= g_{ij} \frac{i}{s} \ {}^j = \ g_{ij} \ {}^i \frac{j}{s}$
   (ii) $= g_{ij} \frac{i}{s} \ {}^j = \ g_{ij} \ {}^i \frac{j}{s}$
   (iii) $\frac{i}{s} = \ g_{ij} \frac{i}{s} \ {}^j \ \ {}^i + \ g_{ij} \frac{i}{s} \ {}^j \ \ {}^i + \ g_{ij} \frac{i}{s} \ {}^j \ \ {}^i$
   (iv) $g_{ij} \frac{i}{s} \ {}^j = 0;$ (v)$g_{ij} \ {}^i \frac{j}{s} = 0;$ (vi)$g_{ij} \frac{i}{s} \ {}^j = 0:$

6. If $a^i = \ {}^i + \ {}^j$, prove that

$$\frac{k}{s} = "^{ijk} a_i \ {}_j; \quad \frac{k}{s} = "^{ijk} a_i \ {}_j; \quad \frac{k}{s} = "^{ijk} a_i \ {}_j:$$

7. Prove that a space curve is helix if and only if

$$"_{ijk} \frac{i}{s} \frac{2\ j}{s^2} \frac{3\ k}{s^3} = 0:$$

8. Find the curvature and torsion at any point of a given curve , given by

$$: \ x^1 = a; x^2 = t; x^3 = ct;$$

where $ds^2 = dx^{1\ 2} + (x^1)^2\ dx^{2\ 2} + dx^{3\ 2}$; $a; c$ are non-zero constants. Also, show that the ratio of the curvature and torsion is a constant.

9. Show that the ratio of the curvature to the torsion of a space curve different from a straight line is a non-zero constant if and only if the curve is a helix.

10. If the curvature and torsion of a space curve are both constants, prove that the curve is a circular helix.

11. If and are the curvature and torsion of a circular helix given in cylindrical co-ordinates x^i by

$$x^1 = a; \ x^2 = t; \ x^3 = bt; b \neq 0;$$

where $a(> 0)$ and b are non-zero constants, show that
   (a) $a \ + b \ = 1:$
   (b) $a = \frac{}{2 + \ 2}; b = \frac{}{2 + \ 2}:$

12. Show that the curvature and torsion of a helix are in a constant ratio to the curvature of the plane section of the cylinder perpendicular to the generators.

13. Defining a Bertrand curve as a space curve for which $a \ + b \ = 1$; where a and b are non-zero constants with $a > 0$, prove that a circular helix is a Bertrand curve.

14. Prove that the principal normal of a cylindrical helix is everywhere perpendicular to the generators of the cylinder.

15. Prove that a circular helix C is the only twisted curve for which more than one curve C exists such that C and C are Bertrand curves.

16. Prove that the product of the torsions of Bertrand curves is constant.

17. Find the curves of which
   (a) the tangent indicatrix
   (b) the binormal indicatrix

   degenerates a point. What does it mean when a spherical image of a closed curve?

18. Investigate the spherical images of a circular helix.

Chapter 6

Intrinsic Geometry of Surface

We will investigate the differential geometry of surfaces by means of tensor calculus. A great advantage of this method lies in the fact that it can immediately be generalized to Riemannian spaces of higher dimension which have assumed increasing importance during the last few decades. In addition, many aspects of the theory of surfaces are simplified when treated with the aid of tensor calculus which thus leads to a better and deeper insight into several problems of differential geometry.

In this chapter we will study the geometric properties of surfaces imbedded in a three-dimensional Euclidean space by means of differential geometry. The reasoning which will lead us to a definition of a surface is similar to that which led us to the concept of a curve. It will be shown that certain of these properties can be phrased independently of the space in which the surface is immersed and that they are concerned solely with the structure of the differential quadratic form for the element of an arc of a curve drawn on a surface. All such properties of surfaces are termed as the intrinsic properties and the geometry based on the study of this differential quadratic form is called the intrinsic geometry of the surface.

6.1 Curvilinear Co-ordinates on a Surface

A surface often arises as the locus of a point P which satisfies some restrictions. We find it convenient to refer the space in which surface is imbedded to a set of orthogonal Cartesian axes Y and regarded the locus of points satisfying the equation

$$F\left(y^1, y^2, y^3\right) = 0 \tag{6.1}$$

as an analytical implicit or constraint definition of a surface S. We suppose that only two of the variables y^i in Eq. (6.1) are independent and that the specification of, say y^1 and y^2 in some region of the Y^1Y^2-plane determines uniquely a real number y^3 such that the $F\left(y^1, y^2, y^3\right)$ reduces to 0. If we suppose that $F\left(y^1, y^2, y^3\right)$, regarded as a function of three independent variables, is of class C^1 in some region R about the point $P_0\left(y_0^1, y_0^2, y_0^3\right)$ with $\left(\frac{\partial F}{\partial y^3}\right)_{P_0} \neq 0$ and $F\left(y_0^1, y_0^2, y_0^3\right) = 0$, then the fundamental theorem on implicit function guarantees the existence of a unique solution $y^3 = f\left(y^1; y^2\right)$, such that $y^3_0 = f\left(y^1_0; y^2_0\right)$.

We are now going to investigate the properties of a surface in its relation to the surrounding space. Consequently, we are dealing with two distinct system of co-ordinates namely, the three curvilinear co-ordinates for the surrounding space which we denote by $y^i;\ i = 1; 2; 3$ and the two curvilinear co-ordinates of the surface which we denote by $u^\alpha;\ \alpha = 1; 2$: A surface S is defined, in general, due to Gauss, as the set of points whose co-ordinates are functions of two independent parameters. Let us denote the equation of a surface S embedded in E^3 by

$$S : y^1 = y^1(u^1; u^2);\ y^2 = y^2(u^1; u^2);\ y^3 = y^3(u^1; u^2)$$

or

$$S : y^i = y^i\left(u^1; u^2\right); i = 1; 2; 3 \tag{6.2}$$

where $u^1_1 \le u^1 \le u^1_2$ and $u^2_1 \le u^2 \le u^2_2$ are parameters and the y^i are real functions of class C^1 in the region of definition of the independent parameters $u^1; u^2$. The function $y^i(u^1; u^2)$ are single-valued and continuous, and are here assumed to possess continuous partial derivatives of the rth order. In this case the surface is said to be of class r. In order to reconcile these two different definitions we shall require that the functions $y^i\left(u^1; u^2\right)$ be such that the Jacobian matrix

$$J = \begin{bmatrix} \frac{\partial y^1}{\partial u^1} & \frac{\partial y^2}{\partial u^1} & \frac{\partial y^3}{\partial u^1} \\ \frac{\partial y^1}{\partial u^2} & \frac{\partial y^2}{\partial u^2} & \frac{\partial y^3}{\partial u^2} \end{bmatrix} \tag{6.3}$$

be of rank 2, so that not all the determinants of the second order selected from this matrix vanish identically in the region of definition of parameters u^i. The three second order matrices

$$J_1 = \begin{bmatrix} \frac{\partial y^2}{\partial u^1} & \frac{\partial y^2}{\partial u^2} \\ \frac{\partial y^3}{\partial u^1} & \frac{\partial y^3}{\partial u^2} \end{bmatrix};\ J_2 = \begin{bmatrix} \frac{\partial y^3}{\partial u^1} & \frac{\partial y^3}{\partial u^2} \\ \frac{\partial y^1}{\partial u^1} & \frac{\partial y^1}{\partial u^2} \end{bmatrix};\ J_3 = \begin{bmatrix} \frac{\partial y^1}{\partial u^1} & \frac{\partial y^1}{\partial u^2} \\ \frac{\partial y^2}{\partial u^1} & \frac{\partial y^2}{\partial u^2} \end{bmatrix}$$

are called permuted submatrices of J. This requirement ensures that it is possible to solve two equations in Eq. (6.2) for u^1 and u^2 in terms of some pair of variables y^i, and the substitution of these solutions in the remaining equation leads to an equation of the form $y^3 = y^3\left(y^1; y^2\right)$. A representation of the form [Eq. (6.2)] is said to be an allowable representation, and parameters $u^1; u^2$ are frequently called curvilinear co-ordinates.

Note that, if any two determinants formed from the matrix [Eq. (6.3)] vanish identically, then the third one also vanishes, provided that the surface S is not a plane parallel to one of the co-ordinate planes.

6.1.1 Nature of Surface Co-ordinates

Since u^1 and u^2 are independent variables, the locus defined by Eq. (6.2) in two-dimensional, and these equations give the co-ordinates y^i of a point on the surface when u^1 and u^2 are assigned particular values. This point of view leads one to consider the surface as a two-dimensional manifold S imbedded in a three-dimensional enveloping space E_3. We can also show surface without reference to the surrounding space, and consider parameters u^1 and u^2 as co-ordinate points in the surface. A familiar example of this is the use of the latitude and longitude as co-ordinates of points on the surface of the earth.

The intersection of a pair of co-ordinate curves obtained by setting $u^1 = u^1_0; u^2 = u^2_0$ determines a point P_0. The variables $u^1; u^2$ determining the point of S are called the curvilinear or Gaussian co-ordinates of the surface (Figure 6.1).

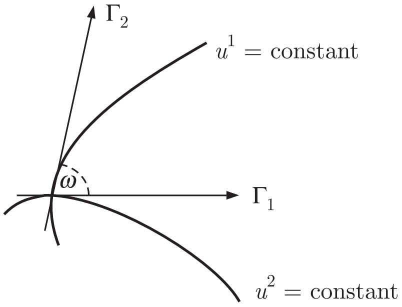

Figure 6.1: Curvilinear co-ordinates.

Obviously, the parametric representation of a surface is not unique and there are infinitely many curvilinear co-ordinate systems which can be used to locate points on a given surface S. For example,

$$x^1 = u^1 + u^2;\; x^2 = u^1 - u^2;\; x^3 = 4u^1u^2$$

and

$$x^1 = v^1 \cosh v^2;\; x^2 = v^1 \sinh v^2;\; x^3 = (v^1)^2$$

represent the same surface

$$(x^1)^2 - (x^2)^2 = x^3; \quad \text{hyperbolic paraboloid.}$$

The two representation may be related by the parametric transformation

$$v^1 = 2\sqrt{u^1u^2};\; v^2 = \frac{1}{2}\log\frac{u^1}{u^2}:$$

Let us examine the geometric significance of these co-ordinates $(u^1; u^2)$. If in Eq. (6.2) of the surface S we put, $u^1 = c$; a constant and let u^2 only vary, we get a locus given by a single variable parameter (one-dimensional manifold). Such a curve

$$S: y^i = y^i\,(c; u^2)\;; i = 1; 2; 3 \qquad (6.4)$$

is called a u^2 curve, characterised by the equation

$$u^2 \text{ curve: } u^1 = \text{ constant.}$$

For different values of u^1, we shall get a family of u^1 curves covering the whole surface. Similarly, for constant value of u^2 we get a family of curves, each called an u^1 curve. In this way we get a family of u^1 curves and a family of u^1 curves, each family covering the whole surface. Thus, u^1 curve is characterised by the equation

$$u^1 \text{ curve: } u^2 = \text{ constant.}$$

Both the families are called family of co-ordinate curves. Together they are called the co-ordinate net. For example, on the surface of revolution $x = u \cos\ ;$ $y = u \sin\ ; z = f(u)$ the parametric curves are

$$u \text{ curve: } x = u \cos c_1; y = u \sin c_1; z = f(u);\ c_1 = \text{ constant.}$$

$$\text{curve: } x = c_2 \cos\ ; y = c_2 \sin\ ; z = f(c_2);\ c_2 = \text{ constant.}$$

EXAMPLE 6.1.1 A surface S is generated by a curve rotating about a fixed straight line. Find a parametric representation of S.

Solution: A surface S generated by a curve rotating about a fixed straight line A is called a surface of revolution. A is called the axis of the surface S. A surface of revolution S; not a cylinder, can be represented in the form (Figure 6.2).

$$\begin{aligned} r &= x^1; x^2; x^3 = x^1\ u^1; u^2\ ; x^2\ u^1; u^2\ ; x^3\ u^1; u^2 \\ &= u^1 \cos u^2; u^1 \sin u^2; f(u^1)\ : \end{aligned}$$

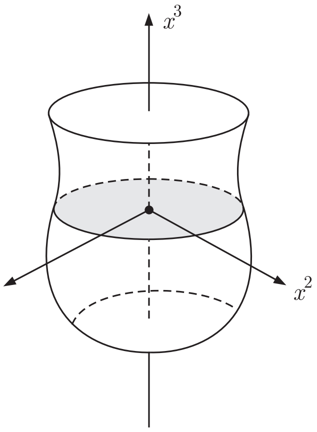

Figure 6.2: Surface of revolution.

This representation is allowable when $u^1 > 0$ and $\frac{df}{du^1} < 1$; i.e. at any point of the rotating curve C which does not lie on the axis A of S or at which the tangent to C is not parallel to A. The curves u^2 = constant are called the meridians, which are the curves of intersection of S and the planes passing through the x^3 axis and the curves u^1 = constant are called parallels, which are the circles parallel to the x^1x^2 plane.

EXAMPLE 6.1.2 Find a parametric representation of a right conoid.

Solution: A surface S is called a right conoid if it can be generated by a moving straight line G intersecting a fixed straight line G_0 so that G and G_0 are always orthogonal. Let us choose the co-ordinates in space so that the straight line G_0 coincides with x^3 axis. Then G is parallel to the x^1x^2 plane, and a right conoid S generated by G can be represented in the form (Figure 6.3)

$$\begin{aligned} r &= \left(x^1; x^2; x^3\right) = \left(x^1\left(u^1; u^2\right); x^2\left(u^1; u^2\right); x^3\left(u^1; u^2\right)\right) \\ &= \left(u^1 \cos u^2; u^1 \sin u^2; f\left(u^2\right)\right): \end{aligned}$$

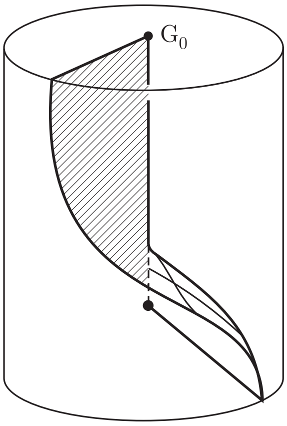

Figure 6.3: Right conoid.

This representation is allowable at any point at which $\frac{df}{du^2} < 1$ and $(u^1)^2 + \left(\frac{df}{du^2}\right)^2 > 0$: The co-ordinate curves u^2 = constant are called straight lines; each value of u^2 corresponds to a certain position of G in space. Any co-ordinate line u^1 = constant is the locus of all points of S which are at the same distance from G_0:

If in particular f is a linear function of u^2, say $f = cu^2 + d$, the corresponding right conoid is called a helicoid. In this case, the curves u^1 = constant are circular helices.

EXAMPLE 6.1.3 Find a parametric representation of a general helicoid.

Solution: A helicoid is a surface generated by the screw motion of a curve about a fixed line, the axis. The various positions of the generating curve thus obtained by first translating it through a distance a parallel to the axis and then rotating it through an angle u^2 about the axis, where $\frac{a}{u^2}$ has a constant value. The constant $\frac{2\pi a}{u^2}$ is the pitch of the helicoids, being the distance translated in one complete revolution. If a twisted curve C rotates about a fixed axis A and, at the same time, is displaced parallel to A so that the velocity of displacement is always proportional to the angular velocity of rotation, then C generates a surface S which is called general helicoid. The intersection M of a helicoid S and a plane passing through the axis A of S is called a meridian of S. The meridians are congruent curves. Consequently, any general helicoid can be generated by a plane curve. We choose as axis A the x^3 axis of the co-ordinate space. Then M can be represented in the form $x^3 = f(u^1)$; where u^1 is the distance of the points of M from A. We assume that at the start of the motion M lies in the x^1x^2 plane. Let u^2 denote the angle of rotation. The displacement of M has the direction of the x^3 axis and is proportional to u^2: We may thus represent S in the form

$$\begin{aligned} r &= \left(x^1; x^2; x^3\right) = \left(x^1\left(u^1; u^2\right); x^2\left(u^1; u^2\right); x^3\left(u^1; u^2\right)\right) \\ &= \left(u^1 \cos u^2; u^1 \sin u^2; cu^2 + f(u^1)\right): \end{aligned}$$

where C is a constant, and $2c$ is called the pitch of the helicoidal motion. If $c \neq 0$ this local representation is allowable at any point at which the tangent to M is not parallel to A. The curves u^1 = constant are circular helices; the curves u^2 = constant are the meridians of the helicoid.

EXAMPLE 6.1.4 Find the parametric representation of the sphere.

Solution: Here we are dealing with a surface of a sphere of radius, and that three mutually perpendicular diameters are chosen as co-ordinate axes. The sphere of radius r with centre at (0, 0, 0) can be represented in the form Eq. (6.1) by $\sum_{i=1}^{n} (x^i)^2 - r^2 = 0$. The latitude u^2 of a point P on the surface may be defined as the inclination of the radius through P to the x^1x^2 plane, and the longitude u^1 as the inclination of the plane containing P and the x^3-axis to the x^3x^1-plane. From this we can obtain a representation of the form (6.2)

$$x^3 = \pm\sqrt{r^2 - (x^1)^2 - (x^2)^2};$$

depending on the choice of the sign this is a representation of one of the two hemispheres $x^3 \geq 0$ and $x^3 \leq 0$. The parametric representation of the sphere under consideration is (Figure 6.4)

$$r = (x^1; x^2; x^3) = (r \cos u^2 \cos u^1; r \cos u^2 \sin u^1; r \sin u^2)$$

or, at length

$$x^1 = r\cos u^2 \cos u^1;\ x^2 = r\cos u^2 \sin u^1;\ x^3 = r\sin u^2$$

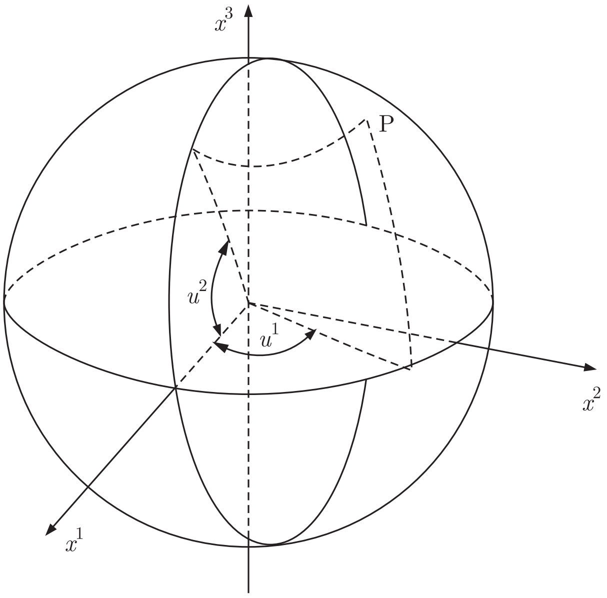

Figure 6.4: Parametric representation of sphere.

where 0 $u^1 < 2$; $\frac{1}{2}$ u^2 $\frac{1}{2}$ are polar angles. This co-ordinate system is used especially in geography for determining the latitude and longitude of points on the globe. Indeed, the co-ordinate curves u^1 = constant and u^2 = constant are the great circles 'meridians' and 'parallels', respectively. The 'equator' is given by $u^2 = 0$ and the 'poles' by $u^2 = \frac{1}{2}$. At the poles the corresponding matrix

$$J = \begin{array}{ccc} r\cos u^2 \sin u^1 & r\cos u^2 \cos u^1 & 0 \\ r\sin u^2 \cos u^1 & r \quad \sin u^2 \sin u^1 & r\cos u^2 \end{array}$$

is of rank 1, i.e. these points are singular with respect to the representation. Every co-ordinate curve u^1 = const. Passes through these points, are the curves $u^2 = \frac{1}{2}$ degenerateinto points. If these two systems of curves cut each other at right angles, we say the parametric curves are orthogonal.

EXAMPLE 6.1.5 Find the parametric representation of a cone of revolution.

Solution: A cone of revolution with apex at (0, 0, 0) and with x^3 axis as axis of revolution can be represented in the form

$$a^2 \ (x^1)^2 + (x^2)^2 \qquad (x^3)^2 = 0$$

The resulting representation of the form

$$x^3 = a\sqrt{(x^1)^2 + (x^2)^2}$$

represents one of the two portions $x^3 \quad 0$ and $x^3 \quad 0$ of this Cone, depending on the choice of the sign of the square root. Now,

$$r = (x^1; x^2; x^3) = (u^1 \cos u^2; u^1 \sin u^2; au^1)$$

is the parametric representation (Figure 6.5) of the cone.

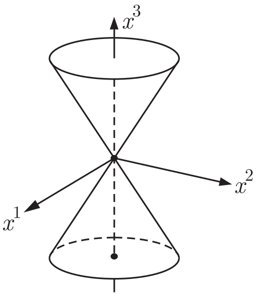

Figure 6.5: Cone of revolution.

The curve u^1 = constant are circles parallel to x_1x_2 plane while the curves u^2 = constant are the generating straight lines of the cone. The corresponding matrix

$$J = \begin{matrix} \cos u^2 & \sin u^2 & a \\ u^1 \sin u^2 & u^1 \cos u^2 & 0 \end{matrix}$$

is of rank 1 at $u^1 = 0$; the apex is a singular point of the cone.

EXAMPLE 6.1.6 Find the parametric representation of an elliptical helix.

Solution: An elliptical helix (Figure 6.6) is a helix lying on an elliptical cylinder $\frac{(x^1)^2}{a^2} + \frac{(x^2)^2}{b^2} = 1$ in the $x^1x^2x^3$ space. The parametric representation of the elliptical helix under consideration is given by

$$r = (x^1; x^2; x^3) = (a \cos t; b \sin t; ct)$$

where c is defined as pitch. At length

$$x^1 = a \cos t; x^2 b \sin t; x^3 = ct:$$

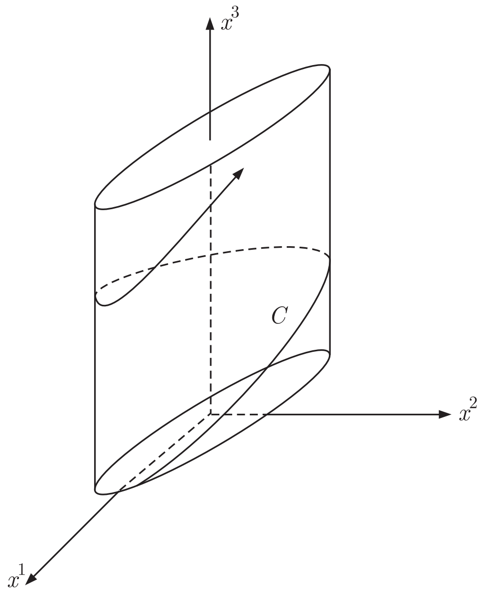

Figure 6.6: Elliptical helix.

6.1.2 Regular Surfaces

Surfaces are generally encountered in the calculus in the form $z = F(x, y)$; i.e. as graphs of two variable functions in three-dimensional space. A surface S in E^2 is the image of a C^3 vector function,

$$r(x^1, x^2) = [f(x^1, x^2), g(x^1, x^2), h(x^1, x^2)],$$

which maps some region V of E^2 into E^3. The co-ordinate breakdown of the mapping r,

$$x = f(x^1, x^2) \quad y = g(x^1, x^2) \quad z = h(x^1, x^2) \tag{6.5}$$

is called the Gaussian form or representation of S. Point P is a regular point of S if $\frac{\partial r}{\partial x^1} \times \frac{\partial r}{\partial x^2} \neq 0$ at P^0, otherwise, P is a singular point. If every point of S is a regular point, then S is a regular surface.

EXAMPLE 6.1.7 Show that $x^1 = u^1 \cos u^2$, $x^2 = u^1 \sin u^2$, $x^3 = u^1 u^2$ is a regular surface.

Solution: The condition which is necessary for

$$r = \left(x^1, x^2, x^3\right) = \left(x^1\left(u^1, u^2\right), x^2\left(u^1, u^2\right), x^3\left(u^1, u^2\right)\right)$$

to be a surface is that $r_{u^1} \times r_{u^2} \neq 0$. Here,

$$r = \left(x^1; x^2; x^3\right) = \left(u^1\cos u^2; u^1\sin u^2; u^1u^2\right):$$

Hence,
$$r_{u^1} = \left(\frac{\partial x^1}{\partial u^1}; \frac{\partial x^2}{\partial u^1}; \frac{\partial x^3}{\partial u^1}\right) = \left(\cos u^2; \sin u^2; u^2\right)$$

$$r_{u^2} = \left(\frac{\partial x^1}{\partial u^2}; \frac{\partial x^2}{\partial u^2}; \frac{\partial x^3}{\partial u^2}\right) = \left(-u^1\sin u^2; u^1\cos u^2; u^1\right)$$

$$\Rightarrow r_{u^1} \times r_{u^2} = \left(u^1\sin u^2 - u^1u^2\cos u^2; u^1u^2\sin u^2 + u^1\cos u^2; u^1\right) \neq 0:$$

Therefore, $x^1 = u^1\cos u^2$, $x^2 = u^1\sin u^2$, $x^3 = u^1u^2$ is a regular surface.

6.2 Intrinsic Geometry

In Section 6.1 we see that the properties of surfaces that can be described without reference to the space in which the surface is imbedded are termed as intrinsic properties. A study of intrinsic properties is made to depend on a certain quadratic differential form describing the metric character of the surface. A transformation T of space co-ordinate from one system x^i to another system $\bar{x}^i$ will be written as

$$T: x^i = x^i\left(\bar{x}^1; \bar{x}^2; \bar{x}^3\right) \tag{6.6}$$

a transformation of Gaussian surface co-ordinates will be

$$u^\alpha = u^\alpha\left(\bar{u}^1; \bar{u}^2\right): \tag{6.7}$$

We will now determine the element of arc of such a curve. Suppose that all functions appearing here are of class C^2 in the region of their definition. Let P and Q be two neighbouring points on the surface S with co-ordinates u^α and $u^\alpha + du^\alpha$, respectively, then from Eq. (6.2), we get

$$y^i = y^i\left(u^1; u^2\right) \text{ so that } dy^i = \frac{\partial y^i}{\partial u^\alpha}du^\alpha \tag{6.8}$$

where the y^i are the orthogonal Cartesian co-ordinates covering the space E^3 in which the surface S is imbedded, and a curve C on S defined by

$$C: u^\alpha = u^\alpha(t);\ t_1 \leq t \leq t_2;\ \text{so that, } du^\alpha = \frac{du^\alpha}{dt}dt; \tag{6.9}$$

where the u^αs are the Gaussian co-ordinates covering S. Viewed from the surrounding space, the curve defined by Eq. (6.9) is a curve in a three-dimensional Euclidean space and its element of arc is given by the formula

$$
\begin{aligned}
ds^2 = dy^i dy^i &= \frac{\partial y^i}{\partial u^\alpha}\frac{\partial y^i}{\partial u^\beta} du^\alpha du^\beta \\
&= a_{\alpha\beta}\, du^\alpha du^\beta \text{ (say); where } a_{\alpha\beta} = \frac{\partial y^i}{\partial u^\alpha}\frac{\partial y^i}{\partial u^\beta}. \qquad (6.10)
\end{aligned}
$$

The expression for ds^2, namely Eq. (6.10), is the square of the linear element of C lying on the surface S, and the right-hand member of Eq. (6.10), i.e. $a_{\alpha\beta}\, du^\alpha du^\beta$ is called the metric form or first fundamental quadratic form of the surface. $a_{\alpha\beta}$s are functions of u's and is called the coefficients of the first fundamental form. The first fundamental form of a regular surface is positive definite. This form (6.10) enable us to measure arc lengths, angles, and areas on a surface; so it defines a metric on the surface.

The length of arc of the curve defined by Eq. (6.7) is given by

$$
S = \int_{t_1}^{t_2} \sqrt{a_{\alpha\beta}\, \dot{u}^\alpha \dot{u}^\beta}\, dt; \text{ where } \dot{u}^\alpha = \frac{du^\alpha}{dt}. \qquad (6.11)
$$

Since in a non-trivial case $ds^2 > 0$, it follows at once from Eq. (6.10) upon setting. u^2 = constant and u^1 = constant in turn, that

$$
ds^2_{(1)} = a_{11}\left(du^1\right)^2 \text{ and } ds^2_{(2)} = a_{22}\left(du^2\right)^2.
$$

Thus, a_{11} and a_{22} are positive functions of u^1 and u^2.

Theorem 6.2.1 Show that $a_{\alpha\beta}$ is a symmetric covariant tensor of order two.

Proof: Consider a transformation of surface co-ordinates

$$
u^\alpha = u^\alpha\left(\bar{u}^1, \bar{u}^2\right) \text{ so that } du^\alpha = \frac{\partial u^\alpha}{\partial \bar{u}^\beta} d\bar{u}^\beta \qquad (6.12)
$$

with the Jacobian $J = \left|\frac{\partial u^\alpha}{\partial \bar{u}^\beta}\right| \neq 0$. The square of the linear element, i.e. ds^2 of C lying on the surface S, is given by the expression

$$
ds^2 = a_{\alpha\beta}\, du^\alpha du^\beta = \frac{\partial y^i}{\partial u^\alpha}\frac{\partial y^i}{\partial u^\beta} du^\alpha du^\beta.
$$

Also

$$
ds^2 = \bar{a}_{\gamma\delta}\, d\bar{u}^\gamma d\bar{u}^\delta = \frac{\partial y^i}{\partial \bar{u}^\gamma}\frac{\partial y^i}{\partial \bar{u}^\delta} d\bar{u}^\gamma d\bar{u}^\delta.
$$

Due to invariant property, we get

$$\frac{\partial y^i}{\partial u}\frac{\partial y^i}{\partial u} du\ du = \frac{\partial y^i}{\partial \bar u}\frac{\partial y^i}{\partial \bar u} d\bar u\ d\bar u$$

or

$$\frac{\partial y^i}{\partial u}\frac{\partial y^i}{\partial u} du\ du = \frac{\partial y^i}{\partial \bar u}\frac{\partial y^i}{\partial \bar u}\frac{\partial \bar u}{\partial u}\frac{\partial \bar u}{\partial u} du\ du$$

or

$$\frac{\partial y^i}{\partial u}\frac{\partial y^i}{\partial u} \quad \frac{\partial y^i}{\partial \bar u}\frac{\partial y^i}{\partial \bar u}\frac{\partial \bar u}{\partial u}\frac{\partial \bar u}{\partial u} \quad du\ du = 0$$

or

$$a \quad \bar a \ \frac{\partial \bar u}{\partial u}\frac{\partial \bar u}{\partial u} \ du\ du = 0$$

Since du ; du are arbitrary tensors, we have

$$a \quad \bar a \ \frac{\partial \bar u}{\partial u}\frac{\partial \bar u}{\partial u} = 0 \ ) \ \bar a = \frac{\partial u}{\partial \bar u}\frac{\partial u}{\partial \bar u} a \ ;$$

which shows that a is a tensor of order two. Now, we have to show that a is symmetric tensor. Let

$$a = \frac{1}{2}(a \quad + a \quad) + \frac{1}{2}(a \quad a \quad)$$

$$= A \quad + B \quad ; \text{ say}$$

where

$$A = \frac{1}{2}(a \quad a \quad) \text{ and } B = \frac{1}{2}(a \quad + a \quad) :$$

It is clear that A is symmetric and B is skew symmetric. Now,

$$a \ du\ du = A \ du\ du + B \ du\ du$$

or

$$(a \quad A \quad) du\ du = B \ du\ du \tag{6.13}$$

or

$$(a \quad A \quad) du\ du = \ B \ du\ du \ ; B \ \text{ is antisymmetric}$$

or

$$(a \quad A \quad) du\ du = \ B \ du\ du \ ;$$

interchanging the dummy indices ;

or

$$(a \quad A \quad) du\ du = \ B \ du\ du \ : \tag{6.14}$$

From Eqs. (6.13) and (6.14) we get

$$2B\ du\ du = 0 \Rightarrow B = 0$$

as du and du are arbitrary tensors. Therefore, $a = A$, where a is a symmetric tensor. Thus, we see that the set of quantities a represents a symmetric covariant tensor of rank 2, with respect to the admissible transformation Eq. (6.12) of surface co-ordinates. The tensor a is called the covariant metric tensor of the surface and are also called fundamental magnitudes of the first order.

Definition 6.2.1 Since the form Eq. (6.10) is positive definite, the determinant

$$a = \begin{vmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{vmatrix} > 0$$

and we can define the reciprocal tensor a by

$$a = \frac{\text{cofactor of } a \text{ in } a}{a}$$

with the property $a\ a =\ $. Also, a is a contravariant tensor of order two. The contravariant tensor a is called the contravariant metric tensor. a is called the discriminant of the form.

Since our space admits of arbitrary contravariant vectors, let be any arbitrary contravariant vector defined at any general point on the surface. Then the equation

$$= a \qquad (6.15)$$

is uniquely solvable if $|a| \neq 0$. This shows that the correspondence is one to one. Since here is a covariant vector, we find that our space admits of arbitrary covariant vector. Taking inner product with a of Eq. (6.15) we get

$$a = a\ a = =$$

or

$$a = = |\ |^2. \qquad (6.16)$$

This relation shows that a is that contravariant tensor of second order. Interchanging the dummy indices and in Eq. (6.16) we get

$$a = |\ |^2.$$

Therefore, a is a symmetric tensor.

EXAMPLE 6.2.1 Find the first fundamental form of a plane with respect to polar co-ordinates.

Solution: Let $x^1 = u^1 \cos u^2, x^2 = u^1 \sin u^2$, where x^1, x^2 are Cartesian co-ordinates and u^1, u^2 are polar co-ordinates. Thus, the parametric representation is given by

$$x^1 = u^1 \cos u^2, x^2 = u^1 \sin u^2, x^3 = 0$$

i.e.

$$\mathbf{r} = (x^1, x^2, x^3) = \left(u^1 \cos u^2, u^1 \sin u^2, 0\right).$$

Thus, the coefficients $a_{\alpha\beta}$ of the first fundamental form are given by

$$a_{11} = \left(\frac{\partial x^1}{\partial u^1}\right)^2 + \left(\frac{\partial x^2}{\partial u^1}\right)^2 + \left(\frac{\partial x^3}{\partial u^1}\right)^2 = 1.$$

$$a_{22} = \left(\frac{\partial x^1}{\partial u^2}\right)^2 + \left(\frac{\partial x^2}{\partial u^2}\right)^2 + \left(\frac{\partial x^3}{\partial u^2}\right)^2 = (u^1)^2.$$

$$\begin{aligned} a_{12} &= \frac{\partial x^i}{\partial u^1}\frac{\partial x^i}{\partial u^2} = \frac{\partial x^1}{\partial u^1}\frac{\partial x^1}{\partial u^2} + \frac{\partial x^2}{\partial u^1}\frac{\partial x^2}{\partial u^2} + \frac{\partial x^3}{\partial u^1}\frac{\partial x^3}{\partial u^2} \\ &= \cos u^2 \left(-u^1 \sin u^2\right) + \sin u^2 (u^1 \cos u^2) + 0 = 0 = a_{21}. \end{aligned}$$

Therefore, the first fundamental form for the surface is given by

$$\begin{aligned} ds^2 &= a_{ij}\, du^i du^j = a_{11}(du^1)^2 + 2a_{12}du^1du^2 + a_{22}(du^2)^2 \\ &= (du^1)^2 + (u^1)^2(du^2)^2. \end{aligned}$$

EXAMPLE 6.2.2 Find the first fundamental form of the right helicoid.

Solution: The parametric representation of the right helicoid is given by

$$x^1 = u^1 \cos u^2, x^2 = u^1 \sin u^2, x^3 = cu^2$$

i.e.

$$\mathbf{r} = (x^1, x^2, x^3) = \left(u^1 \cos u^2, u^1 \sin u^2, cu^2\right),$$

where c is a constant. Now,

$$\frac{\partial x^1}{\partial u^1} = \cos u^2, \quad \frac{\partial x^2}{\partial u^1} = \sin u^2, \quad \frac{\partial x^3}{\partial u^1} = 0$$

$$\frac{\partial x^1}{\partial u^2} = -u^1 \sin u^2, \quad \frac{\partial x^2}{\partial u^2} = u^1 \cos u^2, \quad \frac{\partial x^3}{\partial u^2} = c.$$

Thus, the coefficients a_{ij} of the first fundamental form are given by

$$a_{11} = \left(\frac{\partial x^1}{\partial u^1}\right)^2 + \left(\frac{\partial x^2}{\partial u^1}\right)^2 + \left(\frac{\partial x^3}{\partial u^1}\right)^2 = 1:$$

$$a_{22} = \left(\frac{\partial x^1}{\partial u^2}\right)^2 + \left(\frac{\partial x^2}{\partial u^2}\right)^2 + \left(\frac{\partial x^3}{\partial u^2}\right)^2 = (u^1)^2 + c^2:$$

$$\begin{aligned} a_{12} &= \frac{\partial x^i}{\partial u^1}\frac{\partial x^i}{\partial u^2} = \frac{\partial x^1}{\partial u^1}\frac{\partial x^1}{\partial u^2} + \frac{\partial x^2}{\partial u^1}\frac{\partial x^2}{\partial u^2} + \frac{\partial x^3}{\partial u^1}\frac{\partial x^3}{\partial u^2} \\ &= \cos u^2(-u^1 \sin u^2) + \sin u^2(u^1 \cos u^2) + 0 \cdot c = 0 = a_{21}: \end{aligned}$$

Therefore, the first fundamental form for the surface is given by

$$\begin{aligned} ds^2 &= a_{ij}\, du^i du^j = a_{11}(du^1)^2 + 2a_{12}du^1du^2 + a_{22}(du^2)^2 \\ &= (du^1)^2 + [(u^1)^2 + c^2](du^2)^2: \end{aligned}$$

The metric for R^2 corresponding to the right helicoid is non-Euclidean. Now, the parameters $u^1; u^2$ which are actual polar co-ordinates in the x^1x^2 plane of E^3, (Figure 6.7) formerly keep that significance when the plane is considered abstractly as parameter space. This is an instance of the formal use of familiar co-ordinate system in non-Euclidean space.

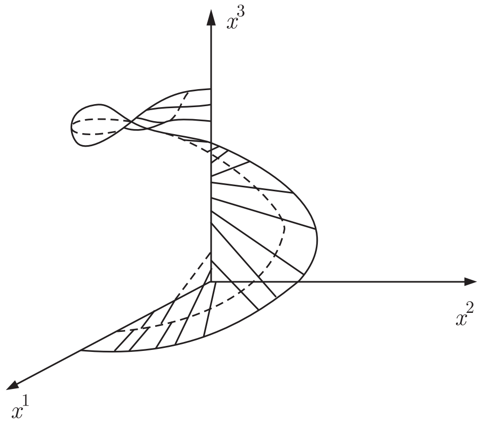

Figure 6.7: Right helicoid.

EXAMPLE 6.2.3 Find the first fundamental form for any surface of revolution, and specialise to a right circular cone (Figure 6.8).

Solution: The Gaussian form of a surface of revolution about z axis is

$$r(x^1; x^2) = \left(f(x^1)\cos x^2; f(x^1)\sin x^2; g(x^1)\right); \; f(x^1) > 0:$$

From this parametric representation, we get

$$\frac{\partial \mathbf{r}}{\partial x^1} = \left(f'(x^1)\cos x^2, f'(x^1)\sin x^2, g'(x^1)\right); \quad \frac{\partial \mathbf{r}}{\partial x^2} = \left(-f(x^1)\sin x^2, f(x^1)\cos x^2, 0\right).$$

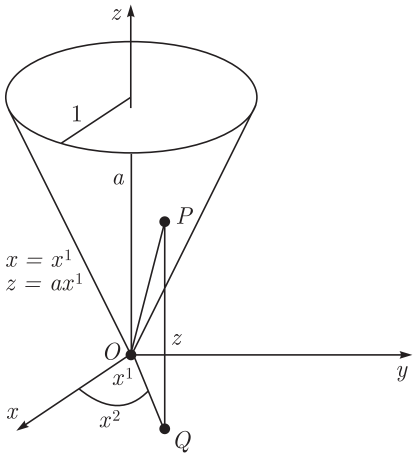

Figure 6.8: Right circular cone.

Thus, the coefficients $a_{\alpha\beta}$ of the first fundamental form are given by

$$a_{11} = \frac{\partial \mathbf{r}}{\partial x^1}\cdot\frac{\partial \mathbf{r}}{\partial x^1} = (f')^2 + (g')^2; \quad a_{22} = \frac{\partial \mathbf{r}}{\partial x^2}\cdot\frac{\partial \mathbf{r}}{\partial x^2} = f^2;$$

$$a_{12} = \frac{\partial \mathbf{r}}{\partial x^1}\cdot\frac{\partial \mathbf{r}}{\partial x^2} = 0 = a_{21}.$$

Therefore, the first fundamental form for the surface is given by

$$\begin{aligned} ds^2 &= a_{11}(dx^1)^2 + 2a_{12}dx^1dx^2 + a_{22}(dx^2)^2 \\ &= \left[(f')^2 + (g')^2\right](dx^1)^1 + f^2(dx^2)^2. \end{aligned}$$

For a right circular cone, $f(x^1) = x^1$ and $g(x^1) = ax^1$; hence,

$$ds^2 = \left[1 + a^2\right](dx^1)^1 + (x^1)^2(dx^2)^2.$$

EXAMPLE 6.2.4 Find the first fundamental form for the catenoid $x = a\cosh x^1$; $z = ax^1$ and compute the length of the curve $x^1 = t, x^2 = t, 0 \le t \le \log(1+\sqrt{2})$.

Solution: For that case, $f(x^1) = a\cosh x^1$; $g(x^1) = ax^1$. Therefore, the first fundamental form for the surface is given by

$$ds^2 = a^2\cosh^2 x^1\left[(dx^1)^2 + (dx^2)^2\right].$$

Thus, the required length of the arc, $0 \le t \le \log(1+\sqrt{2})$ is given by

$$L = a\sqrt{2}\int_0^{\log(1+\sqrt{2})} \cosh t\,dt = a\sqrt{2}\sinh[\log(1+\sqrt{2})] = a\sqrt{2} \text{ units.}$$

EXAMPLE 6.2.5 Find the first fundamental form of the surface is given in Monge's form $x^3 = f(u^1, u^2)$, where the co-ordinates u^1, u^2 may be taken as parameters.

Solution: The parametric representation of the right helicoid is given by

$$x^1 = u^1; \quad x^2 = u^2; \quad x^3 = f(u^1, u^2)$$

i.e.

$$r = (x^1, x^2, x^3) = \left(u^1, u^2, f(u^1, u^2)\right);$$

From this parametric representation, we get

$$\frac{\partial x^1}{\partial u^1} = 1; \quad \frac{\partial x^2}{\partial u^1} = 0; \quad \frac{\partial x^3}{\partial u^1} = \frac{\partial f}{\partial u^1} = f_1$$

$$\frac{\partial x^1}{\partial u^2} = 0; \quad \frac{\partial x^2}{\partial u^2} = 1; \quad \frac{\partial x^3}{\partial u^2} = \frac{\partial f}{\partial u^2} = f_2;$$

where $\frac{\partial f}{\partial u^i} = f_i$. Thus, the coefficients $a_{\alpha\beta}$ of the first fundamental form are given by

$$a_{11} = \frac{\partial x^i}{\partial u^1}\frac{\partial x^i}{\partial u^1} = \left(\frac{\partial x^1}{\partial u^1}\right)^2 + \left(\frac{\partial x^2}{\partial u^1}\right)^2 + \left(\frac{\partial x^3}{\partial u^1}\right)^2 = 1 + f_1^2.$$

$$a_{22} = \frac{\partial x^i}{\partial u^2}\frac{\partial x^i}{\partial u^2} = \left(\frac{\partial x^1}{\partial u^2}\right)^2 + \left(\frac{\partial x^2}{\partial u^2}\right)^2 + \left(\frac{\partial x^3}{\partial u^2}\right)^2 = 1 + f_2^2.$$

$$a_{12} = \frac{\partial x^i}{\partial u^1}\frac{\partial x^i}{\partial u^2} = \frac{\partial x^1}{\partial u^1}\frac{\partial x^1}{\partial u^2} + \frac{\partial x^2}{\partial u^1}\frac{\partial x^2}{\partial u^2} + \frac{\partial x^3}{\partial u^1}\frac{\partial x^3}{\partial u^2} = f_1 f_2 = a_{21}.$$

Therefore, the first fundamental form for the surface is given by

$$ds^2 = a_{ij}\,du^i du^j = a_{11}(du^1)^2 + 2a_{12}du^1du^2 + a_{22}(du^2)^2$$
$$= (1 + f_1^2)(du^1)^1 + 2f_1 f_2 du^1du^2 + [1 + f_2^2](du^2)^2.$$

Note 6.2.1 Along with the first fundamental form, tensor calculus enters the picture. For the intrinsic properties of a particular surface S in E^3 (the properties defined by measurements of distance on the surface) are all implicit in Eq. (6.10), which can be interpreted as a particular Riemannian metrication of the parameter plane. Thus, the study of intrinsic properties of surfaces becomes the tensor analysis of Riemannian matrices in R^2 and this may be conducted without any reference of E^3 whatever. Observe that the metrices under consideration will all be positive definite but not necessarily Euclidean. Accordingly, we shall drop the designation E^2 for the parameter plane, which shall henceforth be referred to general co-ordinates.

6.2.1 Angle Between Two Intersecting Curves

Here, we have to find the angle between two intersecting curves on a surface. The equation of a curve C drawn on the surface S can be written in the form

$$C: u^\alpha = u^\alpha(t); t_1 \leq t \leq t_2. \tag{6.17}$$

Since the $u^\alpha(t)$ is assumed to be of class C^2, the curve C has a continuously turning tangent. Let C_1 and C_2 be two such curves intersecting at the point P of S. We take the equations of S, referred to orthogonal Cartesian axes y^i, in the form

$$y^i = y^i(u_1; u_2); \ i = 1; 2; 3 \tag{6.18}$$

and denote the direction cosines of the tangent lies to C_1 and C_2 at P by ξ^i and η^i, respectively, then

$$\xi^i = \frac{\partial y^i}{\partial u^\alpha}\frac{du^\alpha}{dS_{(1)}} = \frac{dy^i}{dS_{(1)}} \text{ and } \eta^i = \frac{\partial y^i}{\partial u^\alpha}\frac{du^\alpha}{dS_{(2)}} = \frac{dy^i}{dS_{(2)}};$$

where the subscripts 1 and 2 refer to the elements of arc of C_1 and C_2, respectively. We can write the unit vectors in the directions of the tangents C_1 and C_2 as

$$\lambda^\alpha = \frac{du^\alpha}{dS_{(1)}}; \quad \mu^\alpha = \frac{du^\alpha}{dS_{(2)}} \text{ and } \xi^i = \frac{\partial y^i}{\partial u^\alpha}\lambda^\alpha; \quad \eta^i = \frac{\partial y^i}{\partial u^\alpha}\mu^\alpha. \tag{6.19}$$

The cosine of the angle between C_1 and C_2, calculated by a geometer in the enveloping space E^3, (Figure 6.9) is

$$\begin{aligned} \cos\theta &= \xi^i \eta^i = \frac{\partial y^i}{\partial u^\alpha}\frac{\partial y^i}{\partial u^\beta}\lambda^\alpha\mu^\beta \\ &= a_{\alpha\beta}\lambda^\alpha\mu^\beta = a_{\alpha\beta}\frac{du^\alpha}{dS_{(1)}}\frac{du^\beta}{dS_{(2)}}. \end{aligned} \tag{6.20}$$

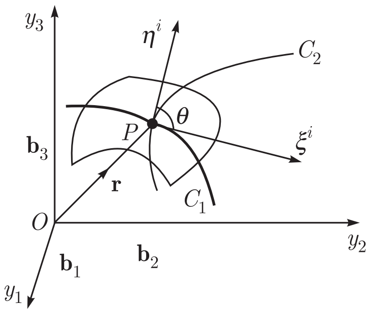

Figure 6.9: Angle between two intersecting curves.

In two-dimensional manifold, the skew-symmetric e-systems can be defined by formula (1.5) as $e_{11} = e_{22} = e^{11} = e^{22} = 0$; $e^{12} = \; e^{21} = e_{12} = \; e_{21} = 1$ and since these systems are relative tensors, the expressions

$$" \;\; = \sqrt{a}\, e \quad \text{and} \; " \;\; = \frac{1}{\sqrt{a}} e \qquad (6.21)$$

are absolute tensors. Let be the angle between two unit vectors ; , then,

$$\sin^2 \;\; = 1 \quad \cos^2 \;\; = \;\; {}^{i}\;{}_{i} \;\; {}^{i}\;{}_{i} \;\; {}^{i}\;{}_{i} \; {}^{2}$$

$$= \;\; {}^{1}_{2} \;\; {}^{1}_{2} \; {}^{2} + {}^{2}_{3} \;\; {}^{2}_{3} \; {}^{2} + {}^{3}_{1} \;\; {}^{3}_{1} \; {}^{2} \text{; by Lagrange identity}$$

$$= \begin{bmatrix} \frac{\partial y^1}{\partial u^1} & \frac{\partial y^1}{\partial u^2} \\ \frac{\partial y^2}{\partial u^1} & \frac{\partial y^2}{\partial u^2} \end{bmatrix}^2 + \begin{bmatrix} \frac{\partial y^2}{\partial u^1} & \frac{\partial y^2}{\partial u^2} \\ \frac{\partial y^3}{\partial u^1} & \frac{\partial y^3}{\partial u^2} \end{bmatrix}^2 + \begin{bmatrix} \frac{\partial y^3}{\partial u^1} & \frac{\partial y^3}{\partial u^2} \\ \frac{\partial y^1}{\partial u^1} & \frac{\partial y^1}{\partial u^2} \end{bmatrix}^2 \;\; {}^{1}_{2} \;\; {}^{1}_{2} \; {}^{2}$$

$$= J_1^2 + J_2^2 + J_3^2 \;\; {}^{1}\;{}^{2} \;\; {}^{2}\;{}^{1} \; {}^{2} = a \;\; {}^{1}\;{}^{2} \;\; {}^{2}\;{}^{1} \; {}^{2}$$

or

$$\sin \;\; = \sqrt{a} \;\; {}^{1}\;{}^{2} \;\; {}^{2}\;{}^{1} = \sqrt{a}\, e \;\;\;\; = " \;\;\;\; : \qquad (6.22)$$

Equation (6.22) " = sin ; is numerically equal to the area of the parallelogram constructed on the unit vectors and . It follows from this result that a necessary and sufficient condition for the orthonormality of two surface unit vectors and is " = 1:

If the curves C_1 and C_2 are orthogonal,

$$a \;\;\;\; = 0 \qquad (6.23)$$

Also, if the surface vectors and are taken along the co-ordinate curves

$$^{1} = \frac{1}{\sqrt{a_{11}}}; \;\; ^{2} = 0; \;\; ^{1} = 0; \text{ and } \; ^{2} = \frac{1}{\sqrt{a_{22}}};$$

then from Eq. (6.23) the co-ordinate curves will form an orthogonal net if and only if $a_{12} = 0$ at every point of the surface. If in particular, the vectors ; are taken along the parametric curves, then, for the u^0-curve, $du^2 = 0$. Consequently, Eq. (6.10) reduces to $dS^2_{(1)} = a_{11} \; du^1 \; ^2$ and hence, the unit vector $_{(1)}$ along u^1 curve is

$$_{(1)} = \frac{du^1}{dS_{(1)}}; \frac{du^2}{dS_{(1)}} \;\; = \;\; \frac{1}{\sqrt{a_{11}}}; 0 \;\; = \frac{1}{\sqrt{a_{11}}} \; _{(1)}:$$

Similarly, the unit vector $_{(2)}$ along u^2 curve is

$$_{(2)} = \frac{du^1}{dS_{(2)}}; \frac{du^2}{dS_{(2)}} \;\; = \;\; \frac{1}{\sqrt{a_{22}}}; 0 \;\; = \frac{1}{\sqrt{a_{22}}} \; _{(2)}:$$

EXAMPLE 6.2.6 Show that the arc length lying on the plane $z = 0$ is the same in both the systems.

Solution: Let P and Q be two points on the plane $z = 0$, whose co-ordinates are say $P\left(x^i\right) = P\left(x^1, x^2, x^3\right)$ and $Q\left(x^i + dx^i\right) = Q\left(x^1 + dx^1, x^2 + dx^2, x^3 + dx^3\right)$. Now, the symmetric tensors a_{ij} are given by

$$a_{11} = \frac{\partial x^i}{\partial u^1}\frac{\partial x^i}{\partial u^1} = \left(\frac{\partial x^1}{\partial u^1}\right)^2 + \left(\frac{\partial x^2}{\partial u^1}\right)^2 + \left(\frac{\partial x^3}{\partial u^1}\right)^2 = 1.$$

$$a_{12} = \frac{\partial x^i}{\partial u^1}\frac{\partial x^i}{\partial u^2} = \frac{\partial x^1}{\partial u^1}\frac{\partial x^1}{\partial u^2} + \frac{\partial x^2}{\partial u^1}\frac{\partial x^2}{\partial u^2} + \frac{\partial x^3}{\partial u^1}\frac{\partial x^3}{\partial u^2} = 0 = a_{21}.$$

$$a_{22} = \frac{\partial x^i}{\partial u^2}\frac{\partial x^i}{\partial u^2} = \left(\frac{\partial x^1}{\partial u^2}\right)^2 + \left(\frac{\partial x^2}{\partial u^2}\right)^2 + \left(\frac{\partial x^3}{\partial u^2}\right)^2 = 1.$$

Now, the square of the linear element is given by

$$\begin{aligned} ds^2 &= a_{\alpha\beta}\, du^\alpha du^\beta = a_{11}\left(du^1\right)^2 + 2a_{12}du^1du^2 + a_{22}\left(du^2\right)^2 \\ &= a_{11}\left(dx^1\right)^2 + 2a_{12}dx^1dx^2 + a_{22}\left(dx^2\right)^2; \\ &\qquad \text{as } u^1 = x^1;\, u^2 = x^2;\, u^3 = 0 \\ &= 1\left(dx^1\right)^2 + 1\left(dx^2\right)^2 = \left(dx^1\right)^2 + \left(dx^2\right)^2 = dx^i dx^i. \end{aligned}$$

Therefore, the arc length lying on the plane $z = 0$ is the same in both the systems.

EXAMPLE 6.2.7 If ω be the angle between the parametric curves lying on a surface, immersed in E_3, show that

$$\cos\omega = \frac{a_{12}}{\sqrt{a_{11}}\sqrt{a_{22}}} \text{ and } \sin\omega = \frac{\sqrt{a}}{\sqrt{a_{11}}\sqrt{a_{22}}}$$

and hence, show that the parametric curves on a surface are orthogonal if $a_{12} = 0$.

Solution: Since ω be the angle between the parametric curves, so,

$$\begin{aligned} \cos\omega &= a_{\alpha\beta}\lambda^\alpha_{(1)}\lambda^\beta_{(2)} = a_{11}\lambda^1_{(1)}\lambda^1_{(2)} + a_{22}\lambda^2_{(1)}\lambda^2_{(2)} + a_{12}\lambda^1_{(1)}\lambda^2_{(2)} + a_{21}\lambda^2_{(1)}\lambda^1_{(2)} \\ &= a_{11}\left(\frac{1}{\sqrt{a_{11}}}\right)(0) + a_{22}(0)\left(\frac{1}{\sqrt{a_{22}}}\right) + a_{12}\left(\frac{1}{\sqrt{a_{11}}}\right)\left(\frac{1}{\sqrt{a_{22}}}\right) + a_{21}(0)(0) \\ &= \frac{a_{12}}{\sqrt{a_{11}}\sqrt{a_{22}}}. \end{aligned}$$

Using the identity $\cos^2\theta = 1 - \sin^2\theta$ we get

$$\sin^2\theta = 1 - \cos^2\theta = 1 - \frac{a_{12}^2}{a_{11}a_{22}} = \frac{a_{11}a_{22} - a_{12}^2}{a_{11}a_{22}} = \frac{a}{a_{11}a_{22}}$$

$$\Rightarrow \sin\theta = \frac{\sqrt{a}}{\sqrt{a_{11}}\sqrt{a_{22}}}.$$

If the parametric curves on the surface S are orthogonal, i.e. if $\theta = \frac{\pi}{2}$; then,

$$\frac{\sqrt{a}}{\sqrt{a_{11}}\sqrt{a_{22}}} = \sin\frac{\pi}{2} = 1$$

so that a_{11} and $a_{22} \neq 0$ and so $a > 0$ and so,

$$\cos\frac{\pi}{2} = 0 = \frac{a_{12}}{\sqrt{a_{11}}\sqrt{a_{22}}} \Rightarrow a_{12} = 0.$$

EXAMPLE 6.2.8 Prove that the parametric curves on a surface given by $x^1 = a\sin u\cos v;\ x^2 = a\sin u\sin v;\ x^3 = a\cos u$ form an orthogonal system.

Solution: For the given surface, the symmetric covariant tensor $a_{\alpha\beta}$ of order two are given by

$$a_{11} = \left(\frac{\partial x^1}{\partial u}\right)^2 + \left(\frac{\partial x^2}{\partial u}\right)^2 + \left(\frac{\partial x^3}{\partial u}\right)^2$$

$$= (a\cos u\cos v)^2 + (a\cos u\sin v)^2 + (-a\sin u)^2 = a^2.$$

$$a_{22} = \left(\frac{\partial x^1}{\partial v}\right)^2 + \left(\frac{\partial x^2}{\partial v}\right)^2 + \left(\frac{\partial x^3}{\partial v}\right)^2$$

$$= (-a\sin u\sin v)^2 + (a\sin u\cos v)^2 + 0^2 = a^2\sin^2 u$$

$$a_{12} = \frac{\partial x^1}{\partial u}\frac{\partial x^1}{\partial v} + \frac{\partial x^2}{\partial u}\frac{\partial x^2}{\partial v} + \frac{\partial x^3}{\partial u}\frac{\partial x^3}{\partial v}$$

$$= a\cos u\cos v\,(-a\sin u\sin v) + a\cos u\sin v\,(a\sin u\cos v) + (-a\sin u)\,0 = 0 = a_{21}.$$

Since $a_{12} = 0$, so the co-ordinate curves are orthogonal. Let λ and μ be taken along the parametric curves. For the u-curve, $dv = 0$ and for the v-curve, $du = 0$. Thus, the unit vector $\lambda_{(1)}$ along the u-curve is

$$\lambda_{(1)} = \left(\frac{du}{ds_{(1)}}; \frac{dv}{ds_{(1)}}\right) = \left(\frac{1}{\sqrt{a_{11}}}; 0\right) = \left(\frac{1}{a}; 0\right)$$

and the unit vector $_{(2)}$ along the v-curve is

$$_{(2)} = \frac{du}{ds_{(2)}}; \frac{dv}{ds_{(2)}} = 0; p\frac{1}{\overline{a_{22}}} = 0; \frac{1}{a\sin u} :$$

If be the angle between the parametric curves, then

$$\cos = a \quad {}_{(1)} \quad {}_{(2)} = a_{11} \, {}^{1}_{(1)} \, {}^{1}_{(2)} + a_{22} \, {}^{2}_{(1)} 1 \, {}^{2}_{(2)} + a_{12} \, {}^{1}_{(1)} \, {}^{2}_{(2)}$$

$$= a^2 \quad \frac{1}{a} \quad 0 + a^2 \sin^2 u \quad 0 \quad \frac{1}{a\sin u} + 0 \quad \frac{1}{a} \quad \frac{1}{a\sin u} + 0 \quad 0 \quad 0$$

$$= 0 \ ) \quad = \frac{}{2}:$$

Thus, the parametric curves on the surface given by $x^1 = a\sin u\cos v; x^2 = a\sin u\sin v;$ $x^3 = a\cos u$ form an orthogonal system.

6.2.2 Element of Surface Area

Let r denotes the position vector of any point P on the surface S, and the b_i are the unit vectors directed along the orthogonal co-ordinate axes Y, then from Eq. (6.18) of the surface S can be written in the vector form as

$$r(u_1; u_2) = b_i y^i (u_1; u_2) :$$

According to the representation of the surface S, it follows that

$$ds^2 = dr \quad dr = \frac{@}{@u} \quad \frac{@}{@u} du \quad du$$

$$= a \quad du \quad du \ ; \quad \text{where}, a \quad = \frac{@}{@u} \quad \frac{@}{@u} :$$

Setting $\frac{@}{@u} = a$; where a_1 and a_2 are obviously tangent vectors to the co-ordinate curves, we see that

$$a_{11} = a_1 \quad a_1; \ a_{12} = a_1 \quad a_2; \ a_{22} = a_2 \quad a_2:$$

In the notation of Eq. (6.19) the space components of a_1 and a_2 are ^{i} and ^{i}, respectively. Let us define an element of area d of the surface S by the formula, (Figure 6.10)

$$d \quad = |a_1 \quad a_2| \, du^1 du^2$$

$$= q\overline{a_{11}a_{22} \quad a_{12}^2} \, du^1 du^2 = p\overline{a} \, du^1 du^2:$$

This formula has widely used to calculate the volume element.

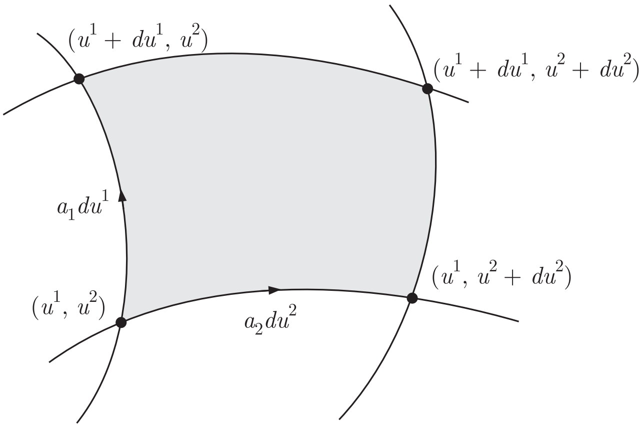

Figure 6.10: Element of area.

EXAMPLE 6.2.9 Find the element of area of the surface of radius r, if the equations of the surface are given in the form

$$y^1 = r\sin u^1\cos u^2;\ y^2 = r\sin u^1\sin u^2;\ y^3 = r\cos u^1;$$

where the y^i are orthogonal Cartesian co-ordinates.

Solution: The parametric representation of the surface of radius r is given by

$$y^1 = r\sin u^1\cos u^2;\ y^2 = r\sin u^1\sin u^2;\ y^3 = r\cos u^1$$

i.e.

$$\mathbf{r} = (y^1; y^2; y^3) = \left(r\sin u^1\cos u^2; r\sin u^1\sin u^2; r\cos u^1\right):$$

From this parametric representation, we get

$$\frac{\partial y^1}{\partial u^1} = r\cos u^1\cos u^2;\ \frac{\partial y^2}{\partial u^1} = r\cos u^1\sin u^2;\ \frac{\partial y^3}{\partial u^1} = -r\sin u^1$$

$$\frac{\partial y^1}{\partial u^2} = -r\sin u^1\sin u^2;\ \frac{\partial y^2}{\partial u^2} = r\sin u^1\cos u^2;\ \frac{\partial y^3}{\partial u^2} = 0:$$

Thus, the coefficients $a_{\alpha\beta}$ of the first fundamental form are given by

$$\begin{aligned} a_{11} &= \left(\frac{\partial y^1}{\partial u^1}\right)^2 + \left(\frac{\partial y^2}{\partial u^1}\right)^2 + \left(\frac{\partial y^3}{\partial u^1}\right)^2 \\ &= \left(r\cos u^1\cos u^2\right)^2 + \left(r\cos u^1\sin u^2\right)^2 + \left(-r\sin u^1\right)^2 = r^2: \\ a_{22} &= \left(\frac{\partial y^1}{\partial u^2}\right)^2 + \left(\frac{\partial y^2}{\partial u^2}\right)^2 + \left(\frac{\partial y^3}{\partial u^2}\right)^2 = r^2\sin^2 u^1: \end{aligned}$$

$$a_{12} = \frac{\partial y^1}{\partial u^1}\frac{\partial y^1}{\partial u^2} + \frac{\partial y^2}{\partial u^1}\frac{\partial y^2}{\partial u^2} + \frac{\partial y^3}{\partial u^1}\frac{\partial y^3}{\partial u^2}$$
$$= \left(r\cos u^1 \cos u^2\right)\left(-r\sin u^1 \sin u^2\right) + \left(r\cos u^1 \sin u^2\right)\left(r\sin u^1 \cos u^2\right)$$
$$+ \left(-r\sin u^1\right) 0 = 0 = a_{21}.$$

Therefore,

$$a = \begin{vmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{vmatrix} = \begin{vmatrix} r^2 & 0 \\ 0 & r^2\sin^2 u^1 \end{vmatrix} = r^4\sin^2 u^1.$$

The element of area $d\sigma$ of the surface S of radius r by the formula,

$$d\sigma = \sqrt{a}\, du^1\, du^2 = r^2 \sin u^1 du^1 du^2.$$

6.3 Geodesic on a Surface

Here, we will discuss the problem of finding curves of minimum length or shortest arc joining a pair of given points on the surface. We will carry out our calculation for the case of the n-dimensional Riemannian manifolds, since our results will be of interest not only in connection with the geometry of surfaces but also in the study of dynamical trajectories. Obviously this is a problem of calculus of variation, first considered by J. Bernoulli.

Let metric properties of the n-dimensional manifold R^n be determined by

$$ds^2 = g_{ij}\, du^i du^j;\ ;\ i, j = 1, 2, \ldots, n; \tag{6.24}$$

where $g_{ij} = g_{ji}$ are specified functions on the variables u^i. Let us suppose that the form Eq. (6.24) is positive definite and the functions g_{ij} are of class C^2. Let C be a curve given by (Figure 6.11)

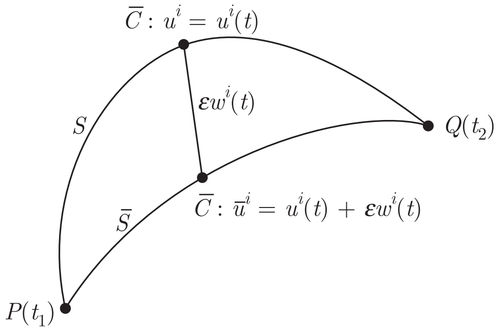
$$C: u^i = u^i(t);\ t_1 \le t \le t_2$$

and the length of the curve between two points P and Q on it be given by

$$S = \int_{t_1}^{t_2} \sqrt{g_{\alpha\beta}\, \dot{u}^\alpha \dot{u}^\beta}\, dt;\ ;\ \alpha, \beta = 1, 2, \cdots, n. \tag{6.25}$$

The extremals of the functional Eq. (6.25) will be termed as *geodesics* in R^n. Let $\overline{C}$ be any curve in the neighbourhood of C joining P and Q and let it be given by

$$\overline{C}: \overline{u}^i = u^i(t) + \varepsilon w^i(t);$$



$\overline{C}: u^i = u^i(t)$
$\varepsilon w^i(t)$
S
$Q(t_2)$
$\bar{S}$
$\overline{C}: \bar{u}^i = u^i(t) + \varepsilon w^i(t)$
$P(t_1)$

Figure 6.11: Geodestic on a surface.

where w^i is a function of t such that $w^i(t) = 0$ at $P(t_1)$ and $Q(t_2)$ and ε is a number of infinitesimal order. The arc length between P and Q along $\overline{C}$ is given by

$$\bar{S} = \int_{t_1}^{t_2} \sqrt{g_{\alpha\beta}\dot{\bar{u}}^\alpha \dot{\bar{u}}^\beta}\, dt.$$

Let us consider the integral,

$$I = \int_{t_1}^{t_2} \phi(u^\alpha; \dot{u}^\alpha) dt;$$

where ϕ is a function and

$$\begin{aligned}\bar{I} &= \int_{t_1}^{t_2} \phi(u^\alpha + \varepsilon w^\alpha; \dot{u}^\alpha + \varepsilon \dot{w}^\alpha)\, dt\\ &= \int_{t_1}^{t_2} \phi(u^\alpha; \dot{u}^\alpha)\, dt + \varepsilon \int_{t_1}^{t_2} \left(w^\alpha \frac{\partial \phi}{\partial u^\alpha} + \dot{w}^\alpha \frac{\partial \phi}{\partial \dot{u}^\alpha}\right) dt;\end{aligned}$$

by Taylor's theorem, on neglecting the other terms. Therefore, the increment $\bar{I} - I$ is given by

$$\begin{aligned}\bar{I} - I &= \varepsilon \int_{t_1}^{t_2} \left(w^\alpha \frac{\partial \phi}{\partial u^\alpha} + \dot{w}^\alpha \frac{\partial \phi}{\partial \dot{u}^\alpha}\right) dt; \quad \alpha = 1; 2\\ &= \varepsilon \int_{t_1}^{t_2} w^\alpha \frac{\partial \phi}{\partial u^\alpha} dt + \varepsilon \int_{t_1}^{t_2} \frac{\partial \phi}{\partial \dot{u}^\alpha} \dot{w}^\alpha\, dt;\\ &= \varepsilon \int_{t_1}^{t_2} w^\alpha \frac{\partial \phi}{\partial u^\alpha}\, dt + \varepsilon \left[\frac{\partial \phi}{\partial \dot{u}^\alpha} w^\alpha\right]_{t_1}^{t_2} - \varepsilon \int_{t_1}^{t_2} \frac{d}{dt}\left(\frac{\partial \phi}{\partial \dot{u}^\alpha}\right) w^\alpha\, dt;\\ &= \varepsilon \int_{t_1}^{t_2} \left(\frac{\partial \phi}{\partial u^\alpha} - \frac{d}{dt}\frac{\partial \phi}{\partial \dot{u}^\alpha}\right) w^\alpha\, dt. \qquad (6.26)\end{aligned}$$

If C is a geodesic, then the increment I must be zero for all neighbouring curves through P and Q, i.e. Eq. (6.26) must vanish for all arbitrary values of the vector w along C. Thus,

$$\frac{d}{dt}\ \frac{\partial}{\partial \dot{u}}\qquad \frac{\partial}{\partial u} = 0; \tag{6.27}$$

which is called Euler's or Lagrange's equations for . In our case,

$$(u\ ;\dot{u}\ ) = \sqrt{g\ \ \dot{u}\ \dot{u}}$$

$$\Rightarrow\ \frac{\partial}{\partial u} = \frac{1}{2}\ g\ \ \dot{u}\ \dot{u}^{\ \ 1/2}\ \frac{\partial g}{\partial u}\dot{u}\ \dot{u}$$

and

$$\frac{\partial}{\partial \dot{u}} = \frac{1}{2}\ g\ \ \dot{u}\ \dot{u}^{\ \ 1/2}\ g\ \ \dot{u}\ :$$

Hence, the Euler's equation [Eq. (6.27)] gives,

$$\frac{d}{dt}\left[\frac{g\ \ \dot{u}}{\sqrt{g\ \ \dot{u}\ \dot{u}}}\qquad \frac{1}{2\sqrt{g\ \ \dot{u}\ \dot{u}}}\frac{\partial g}{\partial u}\dot{u}\ \dot{u}\right] = 0$$

or

$$\frac{d}{dt}\ \frac{g\ \ \dot{u}}{ds/dt}\qquad \frac{1}{2ds/dt}\frac{\partial g}{\partial u}\dot{u}\ \dot{u} = 0$$

or

$$g\ \ u\ \ + \frac{\partial g}{\partial u}\dot{u}\ \dot{u}\qquad \frac{1}{2}\frac{\partial g}{\partial u}\dot{u}\ \dot{u} = \frac{1}{ds/dt}g\ \ \dot{u}\ \frac{d^2s}{dt^2}$$

or

$$g\ \ u\ \ + \frac{1}{2}\ \ \frac{\partial g}{\partial u} + \frac{\partial g}{\partial u}\qquad \frac{\partial g}{\partial u}\ \ \dot{u}\ \dot{u} = \frac{1}{ds/dt}g\ \ \dot{u}\ \frac{d^2s}{dt^2}$$

or

$$g\ \ u\ \ + [\ ;\ \ ]\dot{u}\ \dot{u} = g\ \ \dot{u}\ \frac{d^2s/dt^2}{ds/dt}: \tag{6.28}$$

These are the desired equations of geodesics on an arbitrary surface the Eq. (6.28) of geodesics for the curves of minimal length will play a role similar to that of straight lines in a plane. Also, this can be written as

$$g\ \ g\ \ u\ \ + g\ \ [\ ;\ \ ]\dot{u}\ \dot{u} = g\ \ g\ \ \ \dot{u}\ \frac{d^2s/dt^2}{ds/dt}$$

or

$$u\ \ + \qquad\quad \dot{u}\ \dot{u} = \frac{d^2s/dt^2}{ds/dt}\dot{u}\ : \tag{6.29}$$

If we choose the parameter t to be the arc length s of the curve, i.e. if we get s = t, then,

$$\frac{ds}{dt} = \quad = \sqrt{g \quad \underline{u}\ \underline{u}} = 1 \text{ and } \frac{d^2s}{dt^2} = \frac{d}{dt} = 0$$

then Eq. (6.28) reduces to

$$g \quad u \ + [\ \ ;\ \ ]\underline{u}\ \underline{u} = 0; \tag{6.30}$$

where '.' denotes the differentiation with respect to the arc parameter s. Multiplying Eq. (6.30) by g and sum, we obtain a simple form of the equations of geodesics in R^n as

$$g \quad g \quad u \ + g \quad [\ \ ;\ \ ]\underline{u}\ \underline{u} = 0;$$

or

$$u \ + \qquad \underline{u}\ \underline{u} = 0$$

or

$$\frac{d^2u}{ds^2} + \qquad \frac{du}{ds}\frac{du}{ds} = 0;\ \ ;\ ;\ \ = 1;2;\ \ ;n; \tag{6.31}$$

which is the differential equation of a geodesic in R^n. Since Eq. (6.31) is an ordinary second order differential equation it possesses a unique solution when the values $u^i(s)$ and the first derivatives $\frac{du^i}{ds}$ are prescribed arbitrarily at a given point $u^i(s_0)$: If we regard a given surface S as a Riemannian two-dimensional manifold R^2, covered by Gaussian co-ordinates u , then Eq. (6.31) takes the form

$$\frac{d^2u}{ds^2} + \qquad \frac{du}{ds}\frac{du}{ds} = 0;\ \ ;\ ;\ \ = 1;2: \tag{6.32}$$

Hence, at each point of S there exists a unique geodesic with an arbitrarily prescribed direction $\quad = \frac{du}{ds}$. Thus, if there exists a unique solution u (s), passing through two given points on S, then the curve u (s) is the curve of shortest length joining these points. The solution of the system (6.32) of second order differential equations will define the geodesics $u^i = u^i(s)$:

Deduction 6.3.1 (Necessary and sufficient condition for a geodesic): Let us introduce

$$T(u \ ;\underline{u} \ ) = \frac{1}{2}g \quad \underline{u}\ \underline{u} \ ;U \quad \frac{d}{dt}\ \frac{@T}{@\underline{u}} \qquad \frac{@T}{@u} = \frac{1}{2T}\frac{dT}{dt}\frac{@T}{@\underline{u}}; \tag{6.33}$$

where ; = 1; 2. The expression U so defined are important in relation to any curve, whether it is a geodesic or not. Now,

$$\underline{u}\ U \ = \frac{d}{dt}\ \ \underline{u}\ \frac{@T}{@\underline{u}} \qquad u \ \frac{@T}{@\underline{u}} \quad \underline{u}\ \frac{@T}{@u} = \frac{d}{dt}(2T) \qquad \frac{dT}{dt} = \frac{dT}{dt}; \tag{6.34}$$

where T is a function of u $\dot{u}$ homogeneous of degree 2 in $\dot{u}$. Since also the expression for U on the right how side of Eq. (6.33) satisfy the same identity, i.e.

$$\dot{u}\quad \frac{1}{2T}\frac{dT}{dt}\frac{\partial T}{\partial \dot{u}} = \frac{1}{2T}\frac{dT}{dt}\quad \dot{u}\frac{dT}{d\dot{u}} = \frac{dT}{dt};$$

it follows that the equations in Eq. (6.33) are not independent, they are therefore equivalent to only one equation for the unknowns u (t). Eliminating $\frac{dT}{dt}$ in Eq. (6.33) we get

$$u \frac{\partial T}{\partial \dot{u}} \quad u \frac{dT}{\partial \dot{u}} = 0 : ; \quad = 1; 2: \tag{6.35}$$

This, then, is necessary for a geodesic. To prove that it is also sufficient, suppose that it is satisfied by functions u (t), whose first derivatives do not vanish simultaneously at any point. The $\frac{\partial T}{\partial \dot{u}}$ cannot vanish together. Hence

$$U = \frac{\partial T}{\partial \dot{u}}; \text{ for some } ;$$

and then from Eq. 6.34 we get

$$\frac{dT}{dt} = \quad \dot{u}\frac{\partial T}{\partial \dot{u}} = 2T \quad) \quad = \frac{1}{2T}\frac{dT}{dt}:$$

The function u (t) therefore satisfy Eq. (6.33).

Deduction 6.3.2 Intrinsic curvature: The intrinsic curvature of a curve C in the surface S is the function

$$e = \sqrt{g_{ij}\, b^i b^j}\,; \quad b^i = \frac{}{s}\frac{dx^i}{ds} \;;$$

where the intrinsic curvature vector b^i is given by

$$b^i = \frac{}{s}\frac{dx^i}{ds} = \frac{d^2x^i}{ds^2} + \begin{matrix} i \\ p\ q \end{matrix}\;\frac{dx^p}{ds}\frac{dx^q}{ds}:$$

Intrinsic curvature can be shown to be the instantaneous rate of change of the angle between the tangent vector of C and another vector in the tangent space that is transported parallelly along the curve. A curve on a surface is a geodesic if and only if its intrinsic curvature e is identically zero.

EXAMPLE 6.3.1 Prove that the curves of the family $\frac{v^3}{u^2}$ = constant are geodesics on the surface with metric $v^2du^2 \quad 2uvdudv + 2u^2dv^2; u > 0; v > 0$.

Solution: Let $\frac{v^3}{u^2} = c(> 0)$ so that the parametric form of the equation of the curve is $u = ct^3; v = ct^2$. Construct.

$$T = \frac{1}{2}\left(v^2\dot{u}^2 - 2uv\dot{u}\dot{v} + 2u^2\dot{v}^2\right)$$

Therefore,

$$\begin{aligned}
&\frac{\partial T}{\partial u} = -v\dot{u}\dot{v} + 2u\dot{v}^2 = 2c^3t^5; \quad \frac{\partial T}{\partial v} = v\dot{u}^2 - u\dot{u}\dot{v} = 3c^3t^6\\
&\frac{\partial T}{\partial \dot{u}} = v^2\dot{u} - uv\dot{v} = c^3t^6; \quad \frac{\partial T}{\partial \dot{v}} = -uv\dot{u} + 2u^2\dot{v} = c^3t^7\\
&U^1 = \frac{d}{dt}(c^3t^6) - 2c^3t^5 = 4c^3t^5; \quad V^2 = \frac{d}{dt}(c^3t^7) - 3c^3t^6 = 4c^3t^6
\end{aligned}$$

Since $V\frac{\partial T}{\partial \dot{u}} - U\frac{\partial T}{\partial \dot{v}} = 0$, i.e. the curve is a geodesic for every value of c.

EXAMPLE 6.3.2 Show that the geodesics are straight lines when the co-ordinates are Cartesian.

Solution: Consider the Euclidean space E^3 of 3 dimensions. In this case, the metric is $ds^2 = g_{ij}\, dx^i dx^j$, where the tensor g_{ij} is denoted by a_{ij} and $g_{ij} = a_{ij} = \delta^i_j$: Thus, the components of the Christofell symbols are given by

$$g_{ij} = \delta^i_j \Rightarrow \left\{ {k \atop i\ j} \right\} = 0 = [\,ij; k\,];$$

relative to E^n. The differential equation of a geodesic in E^n, with Euclidean co-ordinates x^i is

$$\frac{d^2x^i}{ds^2} + \left\{ {i \atop j\ k} \right\} \frac{dx^j}{ds}\frac{dx^k}{ds} = 0$$

or

$$\frac{d^2x^i}{ds^2} = 0 \Rightarrow x^i = a^i s + b^i; \quad s = \text{ arc length},$$

where a^i and b^i are constants with $g_{ij}a^i a^j = 1$: Thus, from each point $x = b$ of space there emanates a geodesic ray in every direction (unit vector) a: This equation can be written in the form

$$\frac{x^1 - b^1}{a^1} = \frac{x^1 - b^1}{a^1} = \frac{x^1 - b^1}{a^1}(= s):$$

The equation $x^i = a^i s + b^i$ represents the equation of straight lines in E^3. Thus in affine co-ordinates, where all g_{ij} are constants and all Christoffel symbols vanish, the geodesics are straight lines.

EXAMPLE 6.3.3 Find the differential equations for the geodesic in spherical co-ordinates.

Solution: The relation between Cartesian and spherical co-ordinates is

$$x^1 = u^1 \sin u^2 \cos u^3;\ x^2 = u^1 \sin u^2 \sin u^3;\ x^3 = u^1 \cos u^2.$$

The expression for the metric in spherical co-ordinates is given by

$$ds^2 = \left(du^1\right)^2 + \left(u^1\right)^2 \left(du^2\right)^2 + \left(u^1\right)^2 \sin^2 u^2 \left(du^3\right)^2.$$

Comparing the given metric, with $ds^2 = a_{ij}\, du^i du^j$, we get

$$a_{11} = 1;\ a_{22} = \left(u^1\right)^2;\ a_{33} = \left(u^1\right)^2 \sin^2 u^2 \text{ and } a_{ij} = 0 \text{ for } i \neq j.$$

$$\Rightarrow\ a = \begin{vmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{vmatrix} = (u^1)^4 \sin^2 u^2.$$

Therefore, the reciprocal tensors are given by

$$a^{11} = \frac{\text{cofactor of } a_{11} \text{ in } a}{a} = 1;\ a^{22} = \frac{\text{cofactor of } a_{22} \text{ in } a}{a} = \frac{1}{(u^1)^2}.$$

$$a^{33} = \frac{\text{cofactor of } a_{33} \text{ in } a}{a} = \frac{1}{(u^1)^2 \sin^2 u^2}.$$

$$a^{12} = 0 = a^{21};\ a^{13} = 0 = a^{31};\ a^{23} = 0 = a^{32}.$$

The non-vanishing Christofell symbols of the second kind are

$$\left\{\begin{matrix}1\\2\ 2\end{matrix}\right\} = u^1;\ \left\{\begin{matrix}2\\1\ 2\end{matrix}\right\} = \frac{1}{(u^1)^2} = \left\{\begin{matrix}2\\2\ 1\end{matrix}\right\};\ \left\{\begin{matrix}2\\3\ 3\end{matrix}\right\} = \sin u^2 \cos u^2;$$

$$\left\{\begin{matrix}3\\1\ 3\end{matrix}\right\} = \frac{1}{u^1} = \left\{\begin{matrix}3\\3\ 1\end{matrix}\right\};\ \left\{\begin{matrix}1\\3\ 3\end{matrix}\right\} = u^1 \sin^2 u^2;\ \left\{\begin{matrix}3\\2\ 3\end{matrix}\right\} = \cot u^2 = \left\{\begin{matrix}3\\3\ 2\end{matrix}\right\}.$$

The differential equation of a geodesic for the surface is given by

$$\frac{d^2u^i}{ds^2} + \left\{\begin{matrix}i\\j\ k\end{matrix}\right\} \frac{du^j}{ds}\frac{du^k}{ds} = 0;\ i, j, k = 1, 2, 3. \tag{6.36}$$

For $i = 1$, the differential equation becomes

$$\frac{d^2u^1}{ds^2} + \left\{\begin{matrix}1\\j\ k\end{matrix}\right\} \frac{du^j}{ds}\frac{du^k}{ds} = 0$$

or

$$\frac{d^2u^1}{ds^2} + \genfrac{}{}{0pt}{}{1}{1\ \ k}\frac{du^1}{ds}\frac{du^k}{ds} + \genfrac{}{}{0pt}{}{1}{2\ \ k}\frac{du^2}{ds}\frac{du^k}{ds} + \genfrac{}{}{0pt}{}{1}{3\ \ k}\frac{du^3}{ds}\frac{du^k}{ds} = 0$$

or

$$\frac{d^2u^1}{ds^2} + \genfrac{}{}{0pt}{}{1}{1\ \ 1}{\frac{du^1}{ds}}^{2} + 2\genfrac{}{}{0pt}{}{1}{1\ \ 2}\frac{du^1}{ds}\frac{du^2}{ds} + 2\genfrac{}{}{0pt}{}{1}{1\ \ 3}\frac{du^1}{ds}\frac{du^3}{ds}$$

$$+ \genfrac{}{}{0pt}{}{1}{2\ \ 2}{\frac{du^2}{ds}}^{2} + 2\genfrac{}{}{0pt}{}{1}{2\ \ 3}\frac{du^2}{ds}\frac{du^3}{ds} + \genfrac{}{}{0pt}{}{1}{3\ \ 3}{\frac{du^3}{ds}}^{2} = 0$$

or

$$\frac{d^2u^1}{ds^2} \quad u^1 {\frac{du^2}{ds}}^{2} \quad u^1 \sin^2 u^2 {\frac{du^3}{ds}}^{2} = 0$$

For i = 2, the differential equation becomes

$$\frac{d^2u^2}{ds^2} + \genfrac{}{}{0pt}{}{2}{j\ \ k}\frac{du^j}{ds}\frac{du^k}{ds} = 0$$

or

$$\frac{d^2u^2}{ds^2} + \genfrac{}{}{0pt}{}{2}{1\ \ k}\frac{du^1}{ds}\frac{du^k}{ds} + \genfrac{}{}{0pt}{}{2}{2\ \ k}\frac{du^2}{ds}\frac{du^k}{ds} + \genfrac{}{}{0pt}{}{2}{3\ \ k}\frac{du^3}{ds}\frac{du^k}{ds} = 0$$

or

$$\frac{d^2u^2}{ds^2} + \genfrac{}{}{0pt}{}{2}{1\ \ 1}{\frac{du^1}{ds}}^{2} + 2\genfrac{}{}{0pt}{}{2}{1\ \ 2}\frac{du^1}{ds}\frac{du^2}{ds} + 2\genfrac{}{}{0pt}{}{2}{1\ \ 3}\frac{du^1}{ds}\frac{du^3}{ds}$$

$$+ \genfrac{}{}{0pt}{}{2}{2\ \ 2}{\frac{du^2}{ds}}^{2} + 2\genfrac{}{}{0pt}{}{2}{2\ \ 3}\frac{du^2}{ds}\frac{du^3}{ds} + \genfrac{}{}{0pt}{}{2}{3\ \ 3}{\frac{du^3}{ds}}^{2} = 0$$

or

$$\frac{d^2u^2}{ds^2} + \frac{2}{(u^1)^2}\frac{du^1}{ds}\frac{du^2}{ds} \quad \sin u^2 \cos u^2 {\frac{du^3}{ds}}^{2} = 0:$$

For i = 3, the differential equation becomes

$$\frac{d^2u^3}{ds^2} + \genfrac{}{}{0pt}{}{3}{j\ \ k}\frac{du^j}{ds}\frac{du^k}{ds} = 0$$

or

$$\frac{d^2u^3}{ds^2} + \genfrac{}{}{0pt}{}{3}{1\ \ k}\frac{du^1}{ds}\frac{du^k}{ds} + \genfrac{}{}{0pt}{}{3}{2\ \ k}\frac{du^2}{ds}\frac{du^k}{ds} + \genfrac{}{}{0pt}{}{3}{3\ \ k}\frac{du^3}{ds}\frac{du^k}{ds} = 0$$

or

$$\frac{d^2u^3}{ds^2}+\begin{Bmatrix}3\\1\;1\end{Bmatrix}\left(\frac{du^1}{ds}\right)^2+2\begin{Bmatrix}3\\1\;2\end{Bmatrix}\frac{du^1}{ds}\frac{du^2}{ds}+2\begin{Bmatrix}3\\1\;3\end{Bmatrix}\frac{du^1}{ds}\frac{du^3}{ds}$$
$$+\begin{Bmatrix}3\\2\;2\end{Bmatrix}\left(\frac{du^2}{ds}\right)^2+2\begin{Bmatrix}3\\2\;3\end{Bmatrix}\frac{du^2}{ds}\frac{du^3}{ds}+\begin{Bmatrix}3\\3\;3\end{Bmatrix}\left(\frac{du^3}{ds}\right)^2=0$$

or

$$\frac{d^2u^3}{ds^2}+\frac{2}{u^1}\frac{du^1}{ds}\frac{du^3}{ds}+\cot u^2\frac{du^2}{ds}\frac{du^3}{ds}=0.$$

EXAMPLE 6.3.4 Find the differential equations for the geodesic in cylindrical co-ordinates.

Solution: The relation between Cartesian and cylindrical co-ordinates is

$$x^1=u^1\cos u^2;\; x^2=u^1\sin u^2;\; x^3=u^3.$$

The expression for the metric in cylindrical co-ordinates is given by

$$ds^2=\left(du^1\right)^2+\left(u^1\right)^2\left(du^2\right)^2+\left(du^3\right)^2;$$

from which, the coefficients $a_{\alpha\beta}$ of the first fundamental form are given by

$$a_{11}=1;\; a_{22}=(u^1)^2;\; a_{33}=1 \text{ and } a_{ij}=0;\text{ for } i\neq j;$$

so that $a=(u^1)^2$. The reciprocal tensors $a^{\alpha\beta}$ are given by

$$a^{11}=1;\; a^{22}=\frac{1}{(u^1)^2};\; a^{33}=1$$
$$a^{12}=0=a^{21};\; a^{13}=0=a^{31};\; a^{23}=0=a^{32}.$$

The non-vanishing Christofell symbols of the second kind are

$$\begin{Bmatrix}1\\2\;2\end{Bmatrix}=-u^1;\quad \begin{Bmatrix}2\\1\;2\end{Bmatrix}=\frac{1}{u^1}=\begin{Bmatrix}2\\2\;1\end{Bmatrix}.$$

The differential equation of a geodesic for the surface is given by Eq. (6.36). For $i=1$, the differential equation becomes

$$\frac{d^2u^1}{ds^2}+\begin{Bmatrix}1\\j\;k\end{Bmatrix}\frac{du^j}{ds}\frac{du^k}{ds}=0$$

or

$$\frac{d^2u^1}{ds^2}+\begin{Bmatrix}1\\1\;k\end{Bmatrix}\frac{du^1}{ds}\frac{du^k}{ds}+\begin{Bmatrix}1\\2\;k\end{Bmatrix}\frac{du^2}{ds}\frac{du^k}{ds}+\begin{Bmatrix}1\\3\;k\end{Bmatrix}\frac{du^3}{ds}\frac{du^k}{ds}=0$$

or

$$\frac{d^2u^1}{ds^2}+\genfrac{}{}{0pt}{}{1}{1\ 1}\ \frac{du^1}{ds}^{\ 2}+2\ \genfrac{}{}{0pt}{}{1}{1\ 2}\ \frac{du^1}{ds}\frac{du^2}{ds}+2\ \genfrac{}{}{0pt}{}{1}{1\ 3}\ \frac{du^1}{ds}\frac{du^3}{ds}$$

$$+\ \genfrac{}{}{0pt}{}{1}{2\ 2}\ \frac{du^2}{ds}^{\ 2}+2\ \genfrac{}{}{0pt}{}{1}{2\ 3}\ \frac{du^2}{ds}\frac{du^3}{ds}+\ \genfrac{}{}{0pt}{}{1}{3\ 3}\ \frac{du^3}{ds}^{\ 2}=0$$

or

$$\frac{d^2u^1}{ds^2}\quad u^1\ \frac{du^2}{ds}^{\ 2}=0$$

For i = 2, the differential equation becomes

$$\frac{d^2u^2}{ds^2}+\ \genfrac{}{}{0pt}{}{2}{j\ \ k}\ \frac{du^j}{ds}\frac{du^k}{ds}=0$$

or

$$\frac{d^2u^2}{ds^2}+\ \genfrac{}{}{0pt}{}{2}{1\ \ k}\ \frac{du^1}{ds}\frac{du^k}{ds}+\ \genfrac{}{}{0pt}{}{2}{2\ \ k}\ \frac{du^2}{ds}\frac{du^k}{ds}+\ \genfrac{}{}{0pt}{}{2}{3\ \ k}\ \frac{du^3}{ds}\frac{du^k}{ds}=0$$

or

$$\frac{d^2u^2}{ds^2}+\genfrac{}{}{0pt}{}{2}{1\ 1}\ \frac{du^1}{ds}^{\ 2}+2\ \genfrac{}{}{0pt}{}{2}{1\ 2}\ \frac{du^1}{ds}\frac{du^2}{ds}+2\ \genfrac{}{}{0pt}{}{2}{1\ 3}\ \frac{du^1}{ds}\frac{du^3}{ds}$$

$$+\ \genfrac{}{}{0pt}{}{2}{2\ 2}\ \frac{du^2}{ds}^{\ 2}+2\ \genfrac{}{}{0pt}{}{2}{2\ 3}\ \frac{du^2}{ds}\frac{du^3}{ds}+\ \genfrac{}{}{0pt}{}{2}{3\ 3}\ \frac{du^3}{ds}^{\ 2}=0$$

or

$$\frac{d^2u^2}{ds^2}+\frac{2}{u^1}\frac{du^1}{ds}\frac{du^2}{ds}=0:$$

EXAMPLE 6.3.5 Find the differential equations of the geodesic for the metric

$$ds^2=(\ dx^1)^2+\ f(x^2)^2\quad (x^1)^2 g(dx^2)^2:$$

Solution: The square of the elementary arc length is given by

$$ds^2=(\ dx^1)^2+\ f(x^2)^2\quad (x^1)^2 g(dx^2)^2:$$

The coefficients a of the first fundamental form are given by

$$a_{11}=1;\ \ a_{22}=(\ x^2)^2\quad (x^1)^2 \text{ and } a_{12}=0=\ a_{21}:$$

so that $a = (x^2)^2 - (x^1)^2$. The reciprocal tensors a^{ij} are given by

$$a^{11} = 1;\ \ a^{22} = \frac{1}{(x^2)^2 - (x^1)^2};\ \ a^{12} = 0 = a^{21}.$$

The non-vanishing Christofell symbols of the second kind are

$$\left\{ {1 \atop 2\ 2} \right\} = x^1;\quad \left\{ {2 \atop 1\ 2} \right\} = -\frac{x^1}{(x^2)^2 - (x^1)^2};\quad \left\{ {2 \atop 2\ 2} \right\} = \frac{x^2}{(x^2)^2 - (x^1)^2}.$$

The differential equation of a geodesic for the surface is given by

$$\frac{d^2x^i}{ds^2} + \left\{ {i \atop j\ k} \right\} \frac{dx^j}{ds}\frac{dx^k}{ds} = 0;\ \ i, j, k = 1, 2. \tag{6.37}$$

For $i = 1$, the differential equation becomes

$$\frac{d^2x^1}{ds^2} + \left\{ {1 \atop j\ k} \right\} \frac{dx^j}{ds}\frac{dx^k}{ds} = 0$$

or

$$\frac{d^2x^1}{ds^2} + \left\{ {1 \atop 1\ k} \right\} \frac{dx^1}{ds}\frac{dx^k}{ds} + \left\{ {1 \atop 2\ k} \right\} \frac{dx^2}{ds}\frac{dx^k}{ds} = 0$$

or

$$\frac{d^2x^1}{ds^2} + \left\{ {1 \atop 1\ 1} \right\} \left(\frac{dx^1}{ds}\right)^2 + 2\left\{ {1 \atop 1\ 2} \right\} \frac{dx^1}{ds}\frac{dx^2}{ds} + \left\{ {1 \atop 2\ 2} \right\} \left(\frac{dx^2}{ds}\right)^2 = 0$$

or

$$\frac{d^2x^1}{ds^2} + x^1 \left(\frac{dx^2}{ds}\right)^2 = 0.$$

For $i = 2$, the differential equation becomes

$$\frac{d^2x^2}{ds^2} + \left\{ {2 \atop j\ k} \right\} \frac{dx^j}{ds}\frac{dx^k}{ds} = 0$$

or

$$\frac{d^2x^2}{ds^2} + \left\{ {2 \atop 1\ k} \right\} \frac{dx^1}{ds}\frac{dx^k}{ds} + \left\{ {2 \atop 2\ k} \right\} \frac{dx^2}{ds}\frac{dx^k}{ds} = 0$$

or

$$\frac{d^2x^2}{ds^2} + \left\{ {2 \atop 1\ 1} \right\} \left(\frac{dx^1}{ds}\right)^2 + 2\left\{ {2 \atop 1\ 2} \right\} \frac{dx^1}{ds}\frac{dx^2}{ds} + \left\{ {2 \atop 2\ 2} \right\} \left(\frac{dx^2}{ds}\right)^2 = 0$$

or

$$\frac{d^2x^2}{ds^2} - \frac{2x^1}{(x^2)^2 - (x^1)^2}\frac{dx^1}{ds}\frac{dx^2}{ds} + \frac{x^2}{(x^2)^2 - (x^1)^2}\left(\frac{dx^2}{ds}\right)^2 = 0;$$

which are the required equations of the geodesic.

EXAMPLE 6.3.6 Find the geodesics on the surface

$$x^1 = u^1 \cos u^2;\ x^2 = u^1 \sin u^2;\ x^3 = 0;$$

embedded in E^3, where x^i are orthogonal Cartesian co-ordinates.

Solution: The square of the elementary arc length is given by

$$\begin{aligned}(ds)^2 &= (dx^1)^2 + (dx^2)^2 + (dx^3)^2\\ &= \ du^1 \cos u^2 + u^1(\ \ \sin u^2)du^2\ ^2 + \ du^1 \sin u^2 + u^1 \cos u^2 du^2\ ^2 + 0\\ &= (du^1)^2 + (u^1)^2(du^2)^2:\end{aligned}$$

The coefficients a of the first fundamental form are given by

$$a_{11} = 1;\ \ a_{22} = (u^1)^2 \text{ and } a_{12} = 0 = a_{21};$$

so that $a = (u^1)^2$: The reciprocal tensors a are given by

$$a^{11} = 1;\ \ a^{22} = \frac{1}{(u^1)^2};\ \ a^{12} = 0 = a^{21}:$$

The non-vanishing Christofell symbols of the second kind are

$$\genfrac{}{}{0pt}{}{1}{2\ 2} = \ \ u^1;\quad \genfrac{}{}{0pt}{}{2}{1\ 2} = \frac{1}{u^1} = \genfrac{}{}{0pt}{}{2}{2\ 1}\ :$$

The differential equation of a geodesic for the surface is given by Eq. (6.37). For $i = 1$, the differential equation becomes

$$\frac{d^2u^1}{ds^2} + \genfrac{}{}{0pt}{}{1}{j\ k}\frac{du^j}{ds}\frac{du^k}{ds} = 0$$

or

$$\frac{d^2u^1}{ds^2} + \genfrac{}{}{0pt}{}{1}{1\ k}\frac{du^1}{ds}\frac{du^k}{ds} + \genfrac{}{}{0pt}{}{1}{2\ k}\frac{du^2}{ds}\frac{du^k}{ds} = 0$$

or

$$\frac{d^2u^1}{ds^2} + \genfrac{}{}{0pt}{}{1}{1\ 1}\ \frac{du^1}{ds}\ ^2 + 2\genfrac{}{}{0pt}{}{1}{1\ 2}\frac{du^1}{ds}\frac{du^2}{ds} + \genfrac{}{}{0pt}{}{1}{2\ 2}\ \frac{du^2}{ds}\ ^2 = 0$$

or

$$\frac{d^2u^1}{ds^2}\quad u^1\ \frac{du^2}{ds}\ ^2 = 0: \tag{i}$$

For $i = 2$, the differential equation becomes

$$\frac{d^2u^2}{ds^2} + \genfrac{}{}{0pt}{}{2}{j\ k}\frac{du^j}{ds}\frac{du^k}{ds} = 0$$

or

$$\frac{d^2u^2}{ds^2} + \genfrac{}{}{0pt}{}{2}{1\ k}\frac{du^1}{ds}\frac{du^k}{ds} + \genfrac{}{}{0pt}{}{2}{2\ k}\frac{du^2}{ds}\frac{du^k}{ds} = 0$$

or

$$\frac{d^2u^2}{ds^2} + \genfrac{}{}{0pt}{}{2}{1\ 1}\frac{du^1}{ds}\ ^{2} + 2\genfrac{}{}{0pt}{}{2}{1\ 2}\frac{du^1}{ds}\frac{du^2}{ds} + \genfrac{}{}{0pt}{}{2}{2\ 2}\frac{du^2}{ds}\ ^{2} = 0$$

or

$$\frac{d^2u^2}{ds^2} + \frac{2}{u^1}\frac{du^1}{ds}\frac{du^2}{ds} = 0;\ \text{i.e.}\ \frac{d^2u^2}{ds^2} = \frac{du^2}{ds} + \frac{2}{u^1}\frac{du^1}{ds} = 0$$

or

$$\log\ \frac{du^2}{ds}\ + 2\log u^1 = \log c;\ c = \text{constant}$$

or

$$\log\ (u^1)^2\frac{du^2}{ds}\ = \log c\,)\ \ \frac{du^2}{ds} = \frac{c}{(u^1)^2}: \tag{ii}$$

Therefore, from Eq. (i) we get

$$\frac{d^2u^1}{ds^2}\quad u^1\frac{c^2}{(u^1)^4} = 0;\ \text{i.e.}\ 2\frac{du^1}{ds}\frac{d^2u^1}{ds^2} = 2\frac{c^2}{(u^1)^3}\frac{du^1}{ds}$$

or

$$\frac{du^1}{ds}\ ^{2} = \quad \frac{c^2}{(u^1)^2} + c_1^2;\ c_1 = \text{constant}$$

$$= c_1^2\ \ 1\quad \frac{c^2}{c_1^2(u^1)^2}\ = c_1^2\frac{(u^1)^2\quad d^2}{(u^1)^2};\ d = \frac{c}{c_1}$$

or

$$\frac{u^1\ \ du^1}{(u^1)^2\quad d^2} = c_1 ds\,)\ \ (u^1)^2 = (c_1 s + e)^2 + d^2;$$

where e is an integration constant. Therefore, from Eq. (ii) we get

$$\frac{du^2}{ds} = \frac{c}{(u^1)^2} = \frac{c}{d^2}\frac{1}{1 + \ \frac{c_1 s + e}{d}\ ^{2}}$$

or

$$u^2 = \frac{c}{d^2}\frac{1}{c_1}\tan\ ^{1}\ \frac{c_1 s + e}{d}$$

or

$$u^2 = \frac{1}{p}\tan\ ^{1}\ \frac{c_1 s + e}{d}\ \ ;\ p = \frac{d^2 c_1}{c}$$

or

$$d\tan(pu^2) = c_1 s + e;$$

which is the required equation of the geodesic.

EXAMPLE 6.3.7 On a right helicoid of pitch $2\pi a$, a geodesic makes as angle α with a generator at a point distant c from the axis $(0 < \alpha < \frac{\pi}{2}; c > 0)$. Find the condition that the geodesics meets the axis.

Solution: The first fundamental form of the right helicoid is given by

$$ds^2 = du^2 + (u^2 + a^2)dv^2.$$

The non-vanishing Christofell symbols of the second kind are

$$\left\{ {1 \atop 2\;2} \right\} = -u; \quad \left\{ {2 \atop 2\;1} \right\} = \frac{u}{u^2 + a^2} = \left\{ {2 \atop 1\;2} \right\}.$$

The differential equation of geodesics are

$$\frac{d^2u}{ds^2} - u\left(\frac{dv}{ds}\right)^2 = 0 \quad \text{and} \quad \frac{d^2v}{ds^2} + \frac{du}{u^2 + a^2}\frac{du}{ds}\frac{dv}{ds} = 0.$$

Thus the first integral of the geodesic equations is

$$\frac{dv}{du} = \pm\frac{k}{\{(u^2 + a^2)(u^2 + a^2 - k^2)\}^{1/2}},$$

where k is an arbitrary positive constant. Further integration in general requires elliptic functions.

The given point is (c, 0) for a suitable choice of axes, and α is the angle between the direction (1, 0) and $\left(\frac{du}{ds}, \frac{dv}{ds}\right)$ at this point, then

$$\tan\alpha = (a_{11}a_{22} - a_{12}^2)^{1/2}\,\frac{dv/ds}{du/ds} = k(c^2 + a^2 - k^2)^{-1/2}$$

$$\Rightarrow \quad k = (c^2 + a^2)^{1/2}\sin\alpha.$$

There are two geodesics satisfying the given initial conditions, but it will be sufficient to consider the one for which $\frac{dv}{du} < 0$ initially. Now we consider the following three cases:

(i) $k^2 > a^2$, i.e. $c\tan\alpha > a$. Since which $\frac{dv}{du} < 0$ initially, u decreases as v increases until

$$u = (k^2 - a^2)^{1/2} = (c^2\sin^2\alpha - a^2\cos^2\alpha)^{1/2}.$$

As v continues to increase, the sign of which $\frac{dv}{du}$ changes and u increases indefinitely. The least distance from the axis is therefore $(c^2\sin^2\alpha - a^2\cos^2\alpha)^{1/2}$.

(ii) $k^2 < a^2$, i.e. $c \tan\ < a$. In this case which $\frac{dv}{du} < 0$ for all v, and u decreases indefinitely as v increases. There is a point on the curve at which u = 0, i.e. the curve meets the axis.

(iii) $k^2 = a^2$, i.e. $c \tan\ = a$. In this special case

$$\frac{dv}{du} = \frac{a}{u\sqrt{u^2 + a^2}} \Rightarrow v = \ + \sinh^{1} \frac{a}{u}$$

where $= \sinh^{1}(a/c)$, as v = 0, when u = c. The geodesic is therefore given by

$$u \sinh(v + \ ) = a; \quad = \sinh^{1}(a/c).$$

As v increases, the curve approaches the axis without reaching it. In the opposite sense, $u \to \infty$ as $v \to$, showing that the generator $v =$ is an asymptote.

6.4 Geodesic Co-ordinates

If a Riemannian space is Euclidean, a co-ordinate system exists in which the components of the metric tensors g_{ij} are constant throughout the space and hence, $\frac{\partial g_{ij}}{\partial x^k} = 0$; for all i, j, k. Consequently, the vanishing of the Christoffel symbols, as Eq. (3.1). This is not true for any Riemannian space. But if in a Riemannian space, there exists a co-ordinate system, in fact infinitely many, with respect to which the Christoffel symbols vanish at a given point, then, that system is called a geodesic co-ordinate system and the point is called the pole of the given system.

Let us consider a surface S whose curvilinear co-ordinates are u^1, u^2 and also consider a point $P(u_0^1, u_0^2)$ on S. If $v\ ;\ = 1, 2$ are the co-ordinates of some net on S, then we consider a transformation

$$u\ = u\ \left(v^1, v^2\right); \quad = 1, 2. \tag{6.38}$$

The second derivative formula yields the relation,

$$\frac{\partial^2 u}{\partial v \partial v} + \underset{u}{\ } \frac{\partial u}{\partial v}\frac{\partial u}{\partial v} = \underset{v}{\ } \frac{\partial u}{\partial v}, \tag{6.39}$$

where $\underset{u}{\ }$ and $\underset{v}{\ }$ are the Christoffel symbols in u co-ordinate system and v co-ordinate system, respectively. However, if there exists a transformation of co-ordinates Eq. (6.38) for which $\underset{v}{\ }$ vanish at P, then for that particular point

$$\frac{\partial^2 u}{\partial v \partial v} + \underset{u}{\ } \frac{\partial u}{\partial v}\frac{\partial u}{\partial v} = 0. \tag{6.40}$$

Next, we exhibit next a solution of the Eq. (6.40) yielding transformation Eq. (6.38) to a co-ordinate system v in which the Christoffel symbols vanish at $P(u_0^1; u_0^2)$ on S. Let us take a second degree polynomial

$$u = u_P + v \qquad {}_P\, v\ v\ ; \tag{6.41}$$

where u_P is the value of u at P. On differentiation, from Eq. (6.41), we get

$$\frac{@u}{@v} = \qquad {}_P\, v \text{ and } \frac{@^2 u}{@v@v} = \qquad {}_P$$

$$\left(\frac{@u}{@v}\right)_P = \quad \text{and} \quad \left(\frac{@^2u}{@v@v}\right)_P = \qquad {}_P : \tag{6.42}$$

Since the Jacobian determinant $\left(\frac{@u}{@v}\right)_P = j \quad j = 1 \neq 0$; so the given transformation is permissible in the neighbourhood of $P(u_0^1; u_0^2)$ on S. Using the formula,

$$u_{;} = \frac{@^2u}{@v@v} \qquad k \quad \frac{@u}{@v^k};$$

we see that at $P(u_0^1; u_0^2)$ on S,

$$\left(u_{;}\right)_P = \left(\frac{@^2u}{@v@v}\right)_P \qquad \left(k\right)_P \left(\frac{@u}{@v^k}\right)_P$$

$$= \qquad {}_P \quad \left(k\right)_P \ {}_k = 0 : \tag{6.43}$$

Therefore, the values in Eq. (6.42) satisfies Eq. (6.40) at P. From Eq. (6.41), we see that at P, the new co-ordinates, given by $v = 0$ are the geodesic co-ordinates.

EXAMPLE 6.4.1 Prove that the co-ordinate system u defined by

$$u = a_m^j (v^m \quad u_0^m) + \frac{1}{2} a_h^j \left\{ \begin{matrix} h \\ l\ m \end{matrix} \right\}_P (v^l \quad u_0^l)(v^m \quad u_0^m)$$

is a geodesic co-ordinate, where the coefficients a_m^j being constants and are such that their determinant do not vanish.

Solution: The necessary and sufficient condition that a system of co-ordinates be geodesic with pole at P are that their second covariant derivatives with respect to the metric of the space all vanish at P. From the given relation,

$$u = a_m^j (v^m \quad u_0^m) + \frac{1}{2} a_h^j \left\{ \begin{matrix} h \\ l\ m \end{matrix} \right\}_P (v^l \quad u_0^l)(v^m \quad u_0^m);$$

we get after differentiation,

$$\frac{\partial u^j}{\partial v^l} = a^j_m \delta^m_l + \frac{1}{2} a^j_h \left\{ \begin{matrix} h \\ l\ m \end{matrix} \right\}_P (v^m - u^m_0) + \frac{1}{2} a^j_h \left\{ \begin{matrix} h \\ l\ m \end{matrix} \right\}_P (v^l - u^l_0)\, \delta^m_l$$

$$= a^j_l + \frac{1}{2} a^j_h \left\{ \begin{matrix} h \\ l\ m \end{matrix} \right\}_P (v^m - u^m_0).$$

$$\Rightarrow \quad \left(\frac{\partial u^j}{\partial v^l} \right)_P = a^j_l .$$

Since the Jacobian determinant $\left| \frac{\partial u^j}{\partial v^l} \right|_P = |a^j_l| \neq 0$; so the given transformation is permissible in the neighbourhood of $P(u^1_0, u^2_0)$ on S. Again differentiating with respect to v^m, we get

$$\left(\frac{\partial^2 u^j}{\partial v^m \partial v^l} \right)_P = a^j_h \left\{ \begin{matrix} h \\ l\ m \end{matrix} \right\}_P .$$

Using the formula,

$$u^j_{;lm} = \frac{\partial^2 u^j}{\partial v^l \partial v^m} - \left\{ \begin{matrix} h \\ l\ m \end{matrix} \right\} \frac{\partial u^j}{\partial v^h},$$

we see that at $P(u^1_0, u^2_0)$ on S,

$$\left(u^j_{;lm} \right)_P = \left(\frac{\partial^2 u^j}{\partial v^l \partial v^m} \right)_P - \left\{ \begin{matrix} h \\ l\ m \end{matrix} \right\}_P \left(\frac{\partial u^j}{\partial v^h} \right)_P$$

$$= a^j_h \left\{ \begin{matrix} h \\ l\ m \end{matrix} \right\}_P - a^j_h \left\{ \begin{matrix} h \\ l\ m \end{matrix} \right\}_P = 0. \qquad (6.44)$$

This shows that the new co-ordinate system u defined in the given relation is a geodesic co-ordinate system with the pole at P.

6.5 Parallel Vector Fields on a Surface

The concept of parallel vector fields along a curve C imbedded in E^3 was generalised by Levi-Civita to curves imbedded in an n-dimensional Riemannian manifolds. As an illustration of the usefulness of the concept, consider a surface S immersed in E^3 and a curve C on S; whose equations are taken in the form

$$C : u^\alpha = u^\alpha(t);\ t_1 \leq t \leq t_2;\quad \alpha = 1, 2 \qquad (6.45)$$

where $u^1; u^2$ are the curvilinear co-ordinates covered by the surface S: Let the metric properties of the surface S are governed by the co-ordinates of the first fundamental form a . Let A be a surface vector field defined along C; then the surface intrinsic derivative of A along C is

$$\frac{A}{t} = \frac{dA}{dt} + \qquad A \frac{du}{dt}; \tag{6.46}$$

which is identical with the form of Eq. (3.39) defining the parallel vector field along a space curve. Thus, if $\frac{A}{t} = 0$, the differential Eq. (6.46) becomes

$$\frac{dA}{dt} + \qquad A \frac{du}{dt} = 0; \tag{6.47}$$

which determines a unique vector field when the components of the vector are specified at an arbitrary point of C as the definition of the parallel vector field along a curve C on the surface S: If the parameter t is chosen as the arc length s and if A is taken as the unit tangent vector to C, i.e. if we take

$$A = \frac{du}{ds} = \quad ; \text{ with } a \qquad = 1;$$

then Eq. (6.47) reduces to

$$\frac{d}{dt} \quad \frac{du}{ds} \quad + \qquad \frac{du}{ds}\frac{du}{ds} = 0$$

or

$$\frac{d^2u}{ds^2} + \qquad \frac{du}{ds}\frac{du}{ds} = 0; \tag{6.48}$$

which is the equation of a geodesic on the surface S: From uniqueness of the solution of Eq. (6.48), it follows that the property of tangency of a parallel vector field to a surface curve is both a necessary and sufficient condition for a geodesic. Also, Eq. (6.47) can be written in the form

$$\frac{d}{dt} \quad \frac{du}{ds} \quad + \qquad \frac{du}{ds}\frac{du}{ds} = 0$$

or

$$\frac{@}{@u} \quad \frac{du}{ds} \quad \frac{du}{ds} + \qquad \frac{du}{ds}\frac{du}{ds} = 0$$

or

$$\frac{@}{@u} \quad \frac{du}{ds} \quad + \qquad \frac{du}{ds} \quad \frac{du}{ds} = 0$$

or

$$\frac{du}{ds}{}_{;}\,\frac{du}{ds} = 0.$$

Therefore, the vector obtained by the parallel propagation of the tangent vector to a geodesic always remains tangent to the geodesic.

6.5.1 Geodesic Parallels

The ‘field of geodesics’ was introduced by Weierstrass. A one-parameter family of geodesics on a surface S is said to be a field of geodesics in a portion S^0 of S if through every point of S^0 there passes (just once) exactly one of those geodesics. For example, a family of parallel straight lines is a field of geodesics in a plane. The generating straight lines of a cylinder constitute a field of geodesics.

Suppose a family of geodesics is given, and that a parameter system is chosen so that the geodesics of the family are the curves v = constant and their orthogonal trajectories are the curves u = constant. Since the co-ordinates are orthogonal, we have $a_{12} = 0$. Since the curves v = constant are geodesics we have

$$(\kappa_g)_{v=\text{constant}} = 0 \Rightarrow \frac{1}{\sqrt{a_{22}}}\frac{\partial}{\partial v}\left(\log\sqrt{a_{11}}\right) = 0 \Rightarrow \frac{\partial a_{11}}{\partial v} = 0,$$

that is a_{11} depends on u only. The metric is of the form

$$ds^2 = a_{11}(u)\,du^2 + a_{22}(u,v)\,dv^2.$$

Consider the distance between any two orthogonal trajectories, say $u = a$ and $u = b$, measured only the geodesic $v = c$. Along $v = c$, $dv = 0$, so

$$ds = \sqrt{a_{11}(u)}\,du.$$

Therefore, the length of a geodesic intercepted between the trajectories $u = a$ and $u = b$ is

$$\int_a^b \sqrt{a_{11}(u)}\,du = c \text{ dependent}.$$

The distance is thus the same along whichever geodesic v = constant it is measured and is called geodesic distance between two curves. Because of this property, the orthogonal trajectories u = constant are called geodesic parallels.

Hence, if we take $\int\sqrt{a_{11}}\,du$ as a new parameter u, the first fundamental form is given by the expression

$$ds^2 = (du)^2 + a_{22}(u,v)(dv)^2 = (du)^2 + a(dv)^2,$$

which is characteristic for geodesic co-ordinates. In this metric the parameter u can be specialized by taking it to be the distance from some fixed parallel to the parallel determined by u, the distance being meased along any geodesic $v = c$, i.e. $a_{11} = 1$. Since a_{11} is now equal to unity, the length of an element of arc of a geodesic is du.

Consider the two points $P; Q$ in which a geodesic is cut by the parallels $u = a; u = b$. The length of the arc of the geodesic joining the two points is $(b \quad a)$. For any other curve joining them the length of arc is

$$\int_P^Q ds = \int_P^Q \sqrt{(du)^2 + a(dv)^2} > \int_a^b du;$$

since a is positive. Thus the distance is least in the case of geodesic. Hence, for any given family of geodesics, a parameter system can be chosen so that the metric takes the form $(du)^2 + a(dv)^2$. The given geodesics are the parametric curves $v =$ constant and their orthogonal trajectories are $u =$ constant, u being the measured along a geodesic from some fixed parallel.

EXAMPLE 6.5.1 Prove that the geodesic is an auto parallel curve.

Solution: An autoparallel curve is a curve whose tangent vector field constituted by the tangents at each point of the curve is a parallel vector field. The differential equation of the geodesic C is given by

$$\frac{d^2x}{ds^2} + \frac{dx}{ds}\frac{dx}{ds} \qquad = 0$$

or

$$\frac{@}{@s} + \quad \frac{dx}{ds} \qquad = 0$$

or

$$\frac{@}{@x} + \qquad \frac{dx}{ds} = 0 \;) \quad {}_{;} \quad = 0;$$

which shows that the curve C possesses the property that the tangents at all its points are parallel. Also, ${}_{;} \quad = 0$ shows that the unit tangent $\quad = \frac{dx}{ds}$ suffers a parallel displacement along a geodesic, i.e. a geodesic is an autoparallel curve.

6.6 Gaussian Curvature

The meaning of the curvature tensors will be explained here in connexion with parallel displacement and absolute differentiation.

Let us consider a surface S; embedded in E^3 whose fundamental tensors are a . On the surface S; where the metric is Eq. (6.10), with $u^1; u^2$ as the Gaussian coordinates for the surface S; the Riemann-Christoffel curvature tensor or simply the curvature tensor is given by

$$R \quad = \frac{\partial}{\partial u} \qquad\qquad \frac{\partial}{\partial u} \qquad\qquad +$$

$$= \quad \frac{\partial}{\partial u} \qquad \frac{\partial}{\partial u} \qquad + \tag{6.49}$$

and the associated tensor is given by

$$R \quad = a \quad R \quad ; \tag{6.50}$$

where R are the components of the Riemann curvature tensor for the surface S; given by

$$R \quad = \frac{\partial}{\partial u}[\ ;\ ] \quad \frac{\partial}{\partial u}[\ ;\ ] + \qquad [\ ;\ ] \qquad [\ ;\ ]: \tag{6.51}$$

Note that, this associated tensor R defined in Eq. (6.50) in skew symmetric in the first two and last two indices. Therefore,

$$R \quad = R \quad = 0;\ \text{i.e. } R_{1212} = \quad R_{2112} = \quad R_{1221} = R_{2121}:$$

Hence, every non-vanishing components of the Riemann curvature tensor for a surface is R_{1212} or to its negative. Let a surface S be immersed in E_3 with metric tensor a . Define a quantity by

$$= \frac{R_{1212}}{a} = \frac{1}{a} a_{1} \ R_{212}; \quad \text{where } a = |a \ | \neq 0 \tag{6.52}$$

$$= \frac{1}{a} a_{1} \quad \frac{\partial}{\partial u^{1}}\ _{2\,2} \quad \frac{\partial}{\partial u^{2}}\ _{2\,1} + \ _{2\,2} \quad ^{1} \quad _{2\,1} \quad ^{2} \quad :$$

Such a quantity is called the total curvature or the Gaussian curvature of the surface S. The Eq. (6.49) is a representation of the Gaussian curvature k in terms of the Christoffel symbols. Since only the metric tensor a and its derivatives are involved in expression (6.52) for , the properties described by are intrinsic properties of the surface S. Let us introduce an e-system e ; e defined by Eq. (1.5), and the permutation tensor by Eq. (6.21). With the help of ε tensor, Eq. (6.52) can also be written in the form

$$R_{1212} = a \quad = \sqrt{a}\ e_{12} \sqrt{a}\ e_{12} \quad = \varepsilon_{12}\varepsilon_{12}:$$

In general

$$R \quad = \text{"} \quad \text{"} \quad : \tag{6.53}$$

Also, we have

$$\text{"} \quad \text{"} \quad = \text{"}^1 \text{"}_1 + \text{"}^2 \text{"}_2 = \text{"}^{11}\text{"}_{11} + \text{"}^{12}\text{"}_{12} + \text{"}^{21}\text{"}_{21} + \text{"}^{22}\text{"}_{22}$$

$$= \sqrt{a}e_{11}\frac{e^{11}}{\sqrt{a}} + \sqrt{a}e_{12}\frac{e^{12}}{\sqrt{a}} + \sqrt{a}e_{21}\frac{e^{21}}{\sqrt{a}} + \sqrt{a}e_{22}\frac{e^{22}}{\sqrt{a}}$$

$$= 0 + 1 + (\quad 1) \quad (\quad 1) + 0 = 2 :$$

Therefore, from Eq. (6.53) we obtain

$$\text{"} \quad \text{"} \quad R \quad = \text{"} \quad \text{"} \quad \text{"} \quad \text{"} \quad = 4$$

or

$$= \frac{1}{4}R \quad \text{"} \quad \text{"} \tag{6.54}$$

from which it is evident that the Gaussian curvature is an invariant. Again, from (6.53), we get

$$a \quad a \quad R \quad = a^{11}a \quad R_{\;11} + a^{22}a \quad R_{\;22} + a^{12}a \quad R_{\;12} + a^{21}a \quad R_{\;21}$$

$$= a^{11}a^{22}R_{2112} + a^{12}a^{21}R_{2121} + a^{21}a^{12}R_{1212} + a^{22}a^{11}R_{1221}$$

$$= \quad a^{11}a^{22}R_{1212} + a^{12}a^{21}R_{1212} + a^{21}a^{12}R_{1212} \quad a^{22}a^{11}R_{1221}$$

$$= 2\,R_{1212} \; a^{12}a^{21} \quad a^{11}a^{22}$$

$$= \quad 2R_{1212} \left[\frac{a_{22}}{a}\frac{a_{11}}{a} \quad \frac{a_{12}}{a} \quad \frac{a_{12}}{a}\right]$$

$$= \quad 2R_{1212} \; \frac{a}{a^2} \; = \quad 2 \; ; \; a = |a \quad | = a_{11}a_{22} \quad a_{12}^2$$

or

$$= \quad \frac{1}{2} \; R; \quad \text{where}\, R = a \quad a \quad R \quad = a \quad R \quad : \tag{6.55}$$

R = R = a R is the Ricci tensor. The invariant R in Eq. (6.55) is sometimes defined as the scalar curvature or Einstein curvature of the surface S: A surface on which holds

$$R \quad = (a \; a \quad a \; a \;) \tag{6.56}$$

where κ is a scalar, is called a **surface of constant curvature**. In particular, if $\kappa = 0$, the surface is called a **flat surface**.

Geometrical properties which are expressible in terms of the first fundamental form, may be called **intrinsic Properties**. Since only metric coefficients $a_{\alpha\beta}$ are involved in the definition of κ in Eq. (6.55), the properties of κ are intrinsic properties of the surface.

EXAMPLE 6.6.1 If the co-ordinate system is orthogonal, show that

$$\kappa = -\frac{1}{2\sqrt{a}}\left[\frac{\partial}{\partial u^1}\left(\frac{1}{\sqrt{a}}\frac{\partial a_{22}}{\partial u^1}\right) + \frac{\partial}{\partial u^2}\left(\frac{1}{\sqrt{a}}\frac{\partial a_{11}}{\partial u^2}\right)\right].$$

Solution: If the system of co-ordinates is orthogonal, then $a_{12} = 0 = a_{21}$. Therefore,

$$a = \begin{vmatrix} a_{11} & 0 \\ 0 & a_{22} \end{vmatrix};\ a^{11} = \frac{1}{a_{11}};\ a^{22} = \frac{1}{a_{22}}.$$

The non-vanishing Christoffel symbols of the first kind are

$$[11;1] = \frac{1}{2}\frac{\partial a_{11}}{\partial u^1};\ [12;1] = \frac{1}{2}\frac{\partial a_{11}}{\partial u^2} = -[11;2]$$

$$[22;1] = -\frac{1}{2}\frac{\partial a_{22}}{\partial u^1} = -[12;2];\ [22;2] = \frac{1}{2}\frac{\partial a_{22}}{\partial u^2}.$$

The non-vanishing Christofell symbols of the second kind are

$$\left\{{1 \atop 1\ 1}\right\} = \frac{1}{2a_{11}}\frac{\partial a_{11}}{\partial u^1};\quad \left\{{1 \atop 1\ 2}\right\} = \frac{1}{2a_{11}}\frac{\partial a_{11}}{\partial u^2};\quad \left\{{1 \atop 2\ 2}\right\} = -\frac{1}{2a_{11}}\frac{\partial a_{22}}{\partial u^1};$$

$$\left\{{2 \atop 1\ 1}\right\} = -\frac{1}{2a_{22}}\frac{\partial a_{11}}{\partial u^2};\quad \left\{{2 \atop 1\ 2}\right\} = \frac{1}{2a_{22}}\frac{\partial a_{22}}{\partial u^1};\quad \left\{{2 \atop 2\ 2}\right\} = \frac{1}{2a_{22}}\frac{\partial a_{22}}{\partial u^2}.$$

Using formula (6.51), the Riemann tensor R_{1212} is given by

$$\begin{aligned} R_{1212} &= \frac{\partial}{\partial u^1}[22;1] - \frac{\partial}{\partial u^2}[21;1] + \left\{{\alpha \atop 2\ 1}\right\}[12;\alpha] - \left\{{\alpha \atop 2\ 2}\right\}[11;\alpha] \\ &= \frac{\partial}{\partial u^1}[22;1] - \frac{\partial}{\partial u^2}[21;1] + \left\{{1 \atop 2\ 1}\right\}[12;1] + \left\{{2 \atop 2\ 1}\right\}[12;2] \\ &\quad - \left\{{1 \atop 2\ 2}\right\}[11;1] - \left\{{2 \atop 2\ 2}\right\}[11;2] \end{aligned}$$

$$= \frac{1}{2}\frac{\partial}{\partial u^1}\left(\frac{\partial a_{22}}{\partial u^1}\right) \quad \frac{1}{2}\frac{\partial}{\partial u^2}\left(\frac{\partial a_{22}}{\partial u^2}\right) + \frac{1}{2a_{11}}\frac{\partial a_{11}}{\partial u^2}\cdot\frac{1}{2}\frac{\partial a_{11}}{\partial u^2}$$

$$+ \frac{1}{2a_{22}}\frac{\partial a_{22}}{\partial u^1} \quad \frac{1}{2}\frac{\partial a_{22}}{\partial u^1} + \frac{1}{2a_{11}}\frac{\partial a_{22}}{\partial u^1}\cdot\frac{1}{2}\frac{\partial a_{11}}{\partial u^1} + \frac{1}{2a_{22}}\frac{\partial a_{22}}{\partial u^2} \quad \frac{1}{2}\frac{\partial a_{11}}{\partial u^2}$$

$$= \frac{1}{2}\left(\frac{\partial^2 a_{11}}{(\partial u^2)^2} + \frac{\partial^2 a_{22}}{(\partial u^1)^2}\right) + \frac{1}{4a_{11}}\left[\left(\frac{\partial a_{11}}{\partial u^2}\right)^2 + \frac{\partial a_{11}}{\partial u^1}\frac{\partial a_{22}}{\partial u^1}\right]$$

$$+ \frac{1}{4a_{22}}\left[\left(\frac{\partial a_{22}}{\partial u^1}\right)^2 + \frac{\partial a_{11}}{\partial u^2}\frac{\partial a_{22}}{\partial u^2}\right]$$

$$= \frac{1}{2\sqrt{a_{11}a_{22}}}\left[\frac{\partial}{\partial u^1}\left(\frac{1}{\sqrt{a_{11}a_{22}}}\frac{\partial a_{22}}{\partial u^1}\right) + \frac{\partial}{\partial u^2}\left(\frac{1}{\sqrt{a_{11}a_{22}}}\frac{\partial a_{11}}{\partial u^2}\right)\right]$$

$$= \frac{1}{2\sqrt{a}}\left[\frac{\partial}{\partial u^1}\left(\frac{1}{\sqrt{a}}\frac{\partial a_{22}}{\partial u^1}\right) + \frac{\partial}{\partial u^2}\left(\frac{1}{\sqrt{a}}\frac{\partial a_{11}}{\partial u^2}\right)\right].$$

This is a representation of the Gaussian curvature in terms of the coefficients of the first fundamental form.

EXAMPLE 6.6.2 Calculate the Gaussian curvature for the surface with metric

$$ds^2 = a^2 \sin^2 u^1 (du^2)^2 + a^2 (du^1)^2.$$

Solution: Comparing the given metric with Eq. (6.10), we get $a_{11} = a^2, a_{22} = a^2 \sin^2 u^1$ and $a_{12} = 0 = a_{21}$, so that

$$\triangle = \begin{vmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{vmatrix} = a^4 \sin^2 u^1.$$

The non-vanishing Christoffel symbols of first kind are

$$[22, 1] = \frac{a^2}{2}\sin 2u^1; \quad [12, 2] = \frac{a^2}{2}\sin 2u^1 = [21, 2].$$

The reciprocal or conjugate tensors are

$$a^{11} = \frac{a^2 \sin^2 u^1}{a^4 \sin^2 u^1} = \frac{1}{a^2}, \quad a^{22} = \frac{a^2}{a^4 \sin^2 u^1} = \frac{1}{a^2 \sin^2 u^1}$$

and $a^{12} = 0 = a^{21}$. The non-vanishing Christoffel symbols of second kind are

$$\left\{ {1 \atop 2\;2} \right\} = a^{1k}[22, k] = a^{11}[22, 1] + a^{12}[22, 2] = \frac{1}{2}\sin 2u^1$$

$$\left\{ {1 \atop 2\;1} \right\} = a^{2k}[21, k] = a^{21}[21, 1] + a^{22}[21, 2] = \cot u^1 = \left\{ {1 \atop 1\;2} \right\}.$$

The Riemann tensor R_{1212} is given by

$$R_{1212} = a_1 \ R_{212} = a_{11}R^1_{212} + a_{12}R^2_{212} = a_{11}R^1_{212}$$

$$= a_{11} \ \frac{\partial}{\partial u^1} \ \genfrac{}{}{0pt}{}{1}{2\ 2} \quad \frac{\partial}{\partial u^2} \ \genfrac{}{}{0pt}{}{1}{2\ 1} \ + \ \genfrac{}{}{0pt}{}{}{2\ 2} \quad \genfrac{}{}{0pt}{}{1}{1} \quad \genfrac{}{}{0pt}{}{}{2\ 1} \quad \genfrac{}{}{0pt}{}{1}{2}$$

$$= a^2 \ \frac{\partial}{\partial u^1} \ \frac{1}{2}\sin 2u^1 \quad \frac{\partial}{\partial u^2} \ \cot u^1 \ + \ \genfrac{}{}{0pt}{}{1}{2\ 2} \ \genfrac{}{}{0pt}{}{1}{1\ 1} \ + \ \genfrac{}{}{0pt}{}{2}{2\ 2} \ \genfrac{}{}{0pt}{}{1}{2\ 1}$$

$$\genfrac{}{}{0pt}{}{1}{2\ 1} \ \genfrac{}{}{0pt}{}{1}{2\ 1} \quad \genfrac{}{}{0pt}{}{2}{2\ 1} \ \genfrac{}{}{0pt}{}{1}{2\ 2}$$

$$= a^2 \quad \cos 2u^1 \quad \cot u^1 \quad \frac{1}{2}\sin 2u^1 \quad = a^2 \sin^2 u^1.$$

The total curvature or the Gaussian curvature of the surface S is given by

$$= \frac{R_{1212}}{4} = \frac{a^2 \sin^2 u^1}{a^4 \sin^2 u^1} = \frac{1}{a^2}.$$

EXAMPLE 6.6.3 For a surface of revolution defined by $x^1 = u^1 \cos u^2$; $x^2 = u^1 \sin u^2$; $x^3 = f(u^1)$; where f is of class C^2, find the Gaussian curvature .

Solution: The parametric representation of the right helicoid is given by

$$x^1 = u^1 \cos u^2; \quad x^2 = u^1 \sin u^2; \quad x^3 = f(u^1)$$

i.e.

$$r = (x^1; x^2; x^3) = \quad u^1 \cos u^2; u^1 \sin u^2; f(u^1) \quad .$$

From this parametric representation, we get

$$\frac{\partial x^1}{\partial u^1} = \cos u^2; \ \frac{\partial x^2}{\partial u^1} = \sin u^2; \ \frac{\partial x^3}{\partial u^1} = \frac{\partial f}{\partial u^1} = f_1$$

$$\frac{\partial x^1}{\partial u^2} = \quad u^1 \sin u^2; \ \frac{\partial x^2}{\partial u^2} = u^1 \cos u^2; \ \frac{\partial x^3}{\partial u^2} = \frac{\partial f}{\partial u^2} = 0;$$

where $\frac{\partial f}{\partial u^1} = f_1$. Thus, the coefficients a of the first fundamental form are given by

$$a_{11} = \quad \frac{\partial x^1}{\partial u^1}^2 + \frac{\partial x^2}{\partial u^1}^2 + \frac{\partial x^3}{\partial u^1}^2 = 1 + f_1^2.$$

$$a_{22} = \quad \frac{\partial x^1}{\partial u^2}^2 + \frac{\partial x^2}{\partial u^2}^2 + \frac{\partial x^3}{\partial u^2}^2 = (u^1)^2.$$

$$a_{12} = \frac{\partial x^1}{\partial u^1}\frac{\partial x^1}{\partial u^2} + \frac{\partial x^2}{\partial u^1}\frac{\partial x^2}{\partial u^2} + \frac{\partial x^3}{\partial u^1}\frac{\partial x^3}{\partial u^2}$$

$$= \cos u^2 (\quad u^1 \sin u^2) + (u^1 \cos u^2) \sin u^2 + f_1 \quad 0 = 0 = a_{21}.$$

Therefore, $a = (1 + f_1^2)(u^1)^2$. The reciprocal tensors $a^{\alpha\beta}$ are given by

$$a^{11} = \frac{1}{1+f_1^2};\quad a^{22} = \frac{1}{(u^1)^2};\quad a^{12} = 0 = a^{21}.$$

The non-vanishing Christoffel symbols of the first kind are

$$[11;1] = \frac{1}{2}\frac{\partial a_{11}}{\partial u^1} = f_1 f_2;\quad [12;2] = \frac{1}{2}\frac{\partial a_{22}}{\partial u^1} = u^1 = [21;2]$$

$$[22;1] = -\frac{1}{2}\frac{\partial a_{22}}{\partial u^1} = -u^1;$$

where we use the notations $f_1 = \frac{df}{du^1}$ and $f_2 = \frac{d^2f}{(du^1)^2}$. The non-vanishing Christoffel symbols of the second kind are

$$\left\{ {1 \atop 1\,1} \right\} = a^{11}[11;1] = \frac{f_1 f_2}{1+f_1^2};\quad \left\{ {1 \atop 2\,2} \right\} = a^{11}[22;1] = -\frac{u^1}{1+f_1^2}$$

$$\left\{ {2 \atop 2\,1} \right\} = a^{22}[21;2] = \frac{1}{u^1} = \left\{ {2 \atop 1\,2} \right\}.$$

The Riemann tensor R_{1212} is given by

$$\begin{aligned}
R_{1212} &= a_{1\alpha} R^{\alpha}_{212} = a_{11}R^1_{212} + a_{12}R^2_{212} = a_{11}R^1_{212}\\
&= a_{11}\left[\frac{\partial}{\partial u^1}\left\{ {1 \atop 2\,2} \right\} - \frac{\partial}{\partial u^2}\left\{ {1 \atop 2\,1} \right\} + \left\{ {\alpha \atop 2\,2} \right\}\left\{ {1 \atop \alpha\,1} \right\} - \left\{ {\alpha \atop 2\,1} \right\}\left\{ {1 \atop \alpha\,2} \right\}\right]\\
&= a_{11}\left[\frac{\partial}{\partial u^1}\left(-\frac{u^1}{1+f_1^2}\right) + \left\{ {1 \atop 2\,2} \right\}\left\{ {1 \atop 1\,1} \right\} + \left\{ {2 \atop 2\,2} \right\}\left\{ {1 \atop 2\,1} \right\}\right.\\
&\qquad \left. - \left\{ {1 \atop 2\,1} \right\}\left\{ {1 \atop 2\,1} \right\} - \left\{ {2 \atop 2\,1} \right\}\left\{ {1 \atop 2\,2} \right\}\right]\\
&= (1+f_1^2)\left[-\frac{1}{1+f_1^2} + \frac{2u^1 f_1 f_2}{(1+f_1^2)^2} + \left(-\frac{u^1}{1+f_1^2}\right)\left(\frac{f_1 f_2}{1+f_1^2}\right) - \frac{1}{u^1}\left(-\frac{u^1}{1+f_1^2}\right)\right]\\
&= (1+f_1^2)\frac{u^1 f_1 f_2}{(1+f_1^2)^2} = \frac{u^1 f_1 f_2}{1+f_1^2}.
\end{aligned}$$

The total curvature K or the Gaussian curvature of the surface S is given by

$$K = \frac{R_{1212}}{4} = \frac{u^1 f_1 f_2}{1+f_1^2}\cdot\frac{1}{(1+f_1^2)(u^1)^2} = \frac{f_1 f_2}{u^1[1+(f_1)^2]^2}.$$

6.7 Isometry

The properties of surfaces (i.e. the lengths of curves, angle between intersecting curves), which have been already stated are expressed completely by means of first fundamental quadratic form ds^2 as given in Eq. (6.10). These properties constitute a body of what is known as the intrinsic geometry of surfaces. We have seen that intrinsic property of a surface depend on the metric tensor of the surface and its derivatives. But the metric of the surface is a local property and it may happen that two surfaces have the same metric.

Two surfaces S_1 and S_2 be such that there exists a co-ordinate system with respect to which the linear element on S_1 and S_2 are characterised by the same metric tensors a , then, they are said to be isometric, and the transformation of parameters is called an isometry. For example, the surfaces of the cylinder and cone are isometric with the Euclidean plane, since these surfaces can be rolled out, or developed, on the plane without changing the lengths of arc elements, and hence without altering the measurements of angles and areas.

The problem of finding surfaces isometric to a plane is of special importance. For this we now introduce the concept of a ruled surface and the developable surface. A surface is called a ruled surface (Figure 6.12) if it contains (at least) one one-parameter family of straight lines which can be chosen as co-ordinate curves on the surface. The straight lines are called generators of a ruled surface. One of the examples of a ruled surface is the hyperbolic paraboloid $\frac{(x^1)^2}{a^2} \quad \frac{(x^2)^2}{b^2} \quad x^3 = 0$ (Figure 6.13).

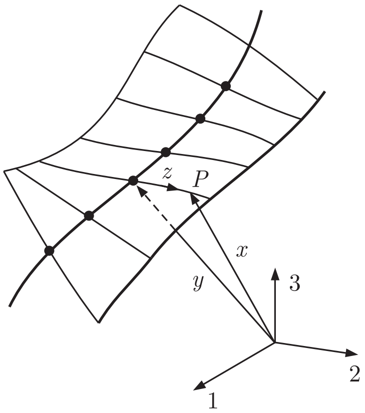


Figure 6.12: Portion of a ruled surface.

Consequently a ruled surface may be generated by a continuous motion of a straight line in space. Such a motion is completely determined if the path $y(s)$ (with arc length s) of a point of the moving line (Figure 6.12) is given and also the direction of the line for every values of s, for example, by a unit vector $z(s)$. A ruled surface may therefore

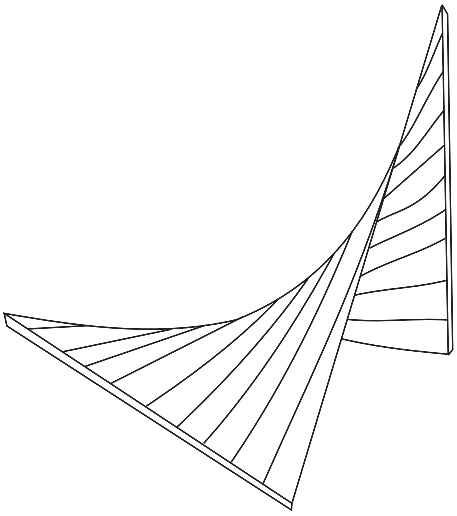

Figure 6.13: Hyperbolic paraboloid.

be represented in the form

$$\mathbf{x}(s;t) = \mathbf{y}(s) + t\mathbf{z}(s). \tag{6.57}$$

Obviously the co-ordinate t is the (directed) distance of the points of this surface Eq. (6.57) from the centre $\mathbf{y}(s)$, measured along the corresponding generator.

A surface which is isometric to a plane is called a *developable surface* or simply *developable*. A developable surface is a special ruled surface with the property that it has the same targent plane at all points on one and same generator. The tangent surface is always a developable surface. The principal normal surface and the binormal surface are developable surfaces if and only if the corresponding curve is plane. Developable surfaces are of particular importance because they are the only surfaces which can be mapped isometrically into a plane. The Gaussian curvature enables us to determine the circumstances under which a given surface is developable or not. The following theorem shows that, a developable surface is a surface which can be developed in a plane:

Theorem 6.7.1 *Prove the $K = 0$ is the necessary and sufficient condition for a surface to be a developable.*

Proof: The Gaussian curvature of the total curvature K of the surface S is given by

$$K = \frac{R_{1212}}{a}; \quad a = |a_{\alpha\beta}|;$$

where the tensor $R_{\alpha\beta\gamma\delta}$ is skew symmetric in the first two and last two indices. Now, when a surface S is isometric with the Euclidean plane, there exists on S a co-ordinate system with respect to which

$$a_{11} = a_{22} = 1;\quad a_{12} = 0 = a_{21} \Rightarrow a = 1 \neq 0.$$

In this case, the Riemann curvature tensor R = 0 for the surface S, in this particular co-ordinate system, and since R is a tensor, it must vanish in every co-ordinate system. Thus $R = 0$; and hence the Gaussian curvature = 0 for the surface S.

Conversely, let = 0, i.e. the Riemann tensors R vanishes at all points of the surface. A necessary and sufficient condition that a symmetric tensor a with $|a| \neq 0$ reduces under a suitable transformation of co-ordinates to a tensor h, where h are constants, is that the Riemann curvature tensor formed from the a s be a zero tensor.

Hence, it guarantees that there exists co-ordinate systems on the surface such that $a_{11} = a_{22} = 1;\ a_{12} = 0$. Hence, the surface is isometric with the Euclidean plane.

EXAMPLE 6.7.1 Prove that the following surfaces:

$$S_1 : y^1 = v^1 \cos v^2;\ y^2 = v^1 \sin v^2;\ y^3 = a \cosh^{-1} \frac{v^1}{a}$$

$$S_2 : y^1 = u^1 \cos u^2;\ y^2 = u^1 \sin u^2;\ y^3 = au^2$$

are isomorphic but non developable.

Solution: The first surface S_1 is the catenoid obtained by revolving the catenary $y^2 = \cosh \frac{y^3}{a}$ about the y^3 axis. Now,

$$a_{11} = \left(\frac{\partial y^i}{\partial v^1}\right)^2 = \left(\frac{\partial y^1}{\partial v^1}\right)^2 + \left(\frac{\partial y^2}{\partial v^1}\right)^2 + \left(\frac{\partial y^3}{\partial v^1}\right)^2$$

$$= (\cos v^2)^2 + (\sin v^2)^2 + \left(\frac{a}{\sqrt{(v^1/a)^2 - 1}}\,\frac{1}{a}\right)^2 = \frac{(v^1)^2}{(v^1)^2 - a^2}.$$

$$a_{22} = \left(\frac{\partial y^i}{\partial v^2}\right)^2 = \left(\frac{\partial y^1}{\partial v^2}\right)^2 + \left(\frac{\partial y^2}{\partial v^2}\right)^2 + \left(\frac{\partial y^3}{\partial v^2}\right)^2$$

$$= (-v^1 \sin v^2)^2 + (v^1 \cos v^2)^2 + 0 = (v^1)^2.$$

$$a_{12} = \frac{\partial y^1}{\partial v^1}\frac{\partial y^1}{\partial v^2} + \frac{\partial y^2}{\partial v^1}\frac{\partial y^2}{\partial v^2} + \frac{\partial y^3}{\partial v^1}\frac{\partial y^3}{\partial v^2}$$

$$= \cos v^2(-v^1 \sin v^2) + \sin v^2(v^1 \cos v^2) + \frac{a}{\sqrt{(v^1)^2 - a^2}}.0 = 0 = a_{21}.$$

Thus, the first fundamental quadratic form for the surface S_1 becomes,

$$\begin{aligned} ds^2 &= a_{\alpha\beta}\,dv^\alpha dv^\beta = a_{11}(dv^1)^2 + a_{22}(dv^2)^2 + 2a_{12}dv^1dv^2 \\ &= \frac{(v^1)^2}{(v^1)^2 - a^2}(dv^1)^2 + (v^1)^2(dv^2)^2 \\ &= \frac{(v^1)^2}{(v^1)^2 - a^2}(dv^1)^2 + [a^2 + \{(v^1)^2 - a^2\}](dv^2)^2. \end{aligned}$$

The second surface S_2 is a right helicoid. Now,

$$\begin{aligned} a_{11} &= \left(\frac{\partial y^i}{\partial u^1}\right)^2 = \left(\frac{\partial y^1}{\partial u^1}\right)^2 + \left(\frac{\partial y^2}{\partial u^1}\right)^2 + \left(\frac{\partial y^3}{\partial u^1}\right)^2 \\ &= (\cos u^2)^2 + (\sin u^2)^2 + 0 = 1\,; \\ a_{22} &= \left(\frac{\partial y^i}{\partial u^2}\right)^2 = \left(\frac{\partial y^1}{\partial u^2}\right)^2 + \left(\frac{\partial y^2}{\partial u^2}\right)^2 + \left(\frac{\partial y^3}{\partial u^2}\right)^2 \\ &= (-u^1\sin u^2)^2 + (u^1\cos u^2)^2 + a^2 = (u^1)^2 + a^2. \\ a_{12} &= \frac{\partial y^1}{\partial u^1}\frac{\partial y^1}{\partial u^2} + \frac{\partial y^2}{\partial u^1}\frac{\partial y^2}{\partial u^2} + \frac{\partial y^3}{\partial u^1}\frac{\partial y^3}{\partial u^2} \\ &= \cos u^2(-u^1\sin u^2) + \sin u^2(u^1\cos u^2) + 0\cdot a = 0. \end{aligned}$$

Thus the first fundamental quadratic form for the surface S_2 is given by

$$\begin{aligned} ds^2 &= a_{\alpha\beta}\,du^\alpha du^\beta = a_{11}(du^1)^2 + a_{22}(du^2)^2 + 2a_{12}du^1du^2 \\ &= (du^1)^2 + [a^2 + (u^1)^2](du^2)^2. \end{aligned}$$

Now, if we set $(v^1)^2 - a^2 = (u^1)^2$ and $v^2 = u^2$, then the two surfaces have the same metric. Thus, the surfaces S_1 and S_2 are isometric.

Now, we calculate the Gaussian curvature for the first surface S_1. The reciprocal tensors for the first fundamental quadratic form are

$$a^{11} = \frac{(v^1)^2 - a^2}{(v^1)^2};\; a^{22} = \frac{1}{(v^1)^2};\; a^{12} = 0 = a^{21}.$$

The non-vanishing Christoffel symbols of first kind are

$$\begin{aligned} [11;1] &= \frac{1}{2}\left(\frac{\partial a_{11}}{\partial v^1} + \frac{\partial a_{11}}{\partial v^1} - \frac{\partial a_{11}}{\partial v^1}\right) = \frac{1}{2}\frac{\partial a_{11}}{\partial v^1} = -\frac{a^2v^1}{[(v^1)^2 - a^2]^2} \\ [22;1] &= \frac{1}{2}\left(\frac{\partial a_{21}}{\partial v^2} + \frac{\partial a_{21}}{\partial v^2} - \frac{\partial a_{22}}{\partial v^1}\right) = -\frac{1}{2}\frac{\partial a_{22}}{\partial v^1} = -v^1 \\ [12;2] &= \frac{1}{2}\left(\frac{\partial a_{12}}{\partial v^2} + \frac{\partial a_{22}}{\partial v^1} - \frac{\partial a_{12}}{\partial v^2}\right) = \frac{1}{2}\frac{\partial a_{22}}{\partial v^1} = v^1 = [21;2]. \end{aligned}$$

The non-vanishing Christoffel symbols of second kind are

$$\left\{\begin{matrix}1\\1\;1\end{matrix}\right\} = a^{1k}[11;k] = a^{11}[11;1] + a^{12}[11;2]$$

$$= \frac{(v^1)^2 - a^2}{(v^1)^2}\left(-\frac{a^2v^1}{[(v^1)^2 - a^2]^2}\right) = -\frac{a^2}{v^1[(v^1)^2 - a^2]}$$

$$\left\{\begin{matrix}1\\2\;2\end{matrix}\right\} = a^{1k}[22;k] = a^{11}[22;1] + a^{12}[22;2]$$

$$= \frac{(v^1)^2 - a^2}{(v^1)^2}\left(-v^1\right) = -\frac{(v^1)^2 - a^2}{v^1}$$

$$\left\{\begin{matrix}2\\2\;1\end{matrix}\right\} = a^{2k}[21;k] = a^{21}[21;1] + a^{22}[21;2] = \frac{v^1}{(v^1)^2} = \frac{1}{v^1} = \left\{\begin{matrix}2\\1\;2\end{matrix}\right\}.$$

The Riemann tensor R_{1212} is given by

$$R_{1212} = a_{1\alpha}R^{\alpha}_{212} = a_{11}R^1_{212} + a_{12}R^2_{212} = a_{11}R^1_{212}$$

$$= a_{11}\left[\frac{\partial}{\partial v^1}\left\{\begin{matrix}1\\2\;2\end{matrix}\right\} - \frac{\partial}{\partial v^2}\left\{\begin{matrix}1\\2\;1\end{matrix}\right\} + \left\{\begin{matrix}\gamma\\2\;2\end{matrix}\right\}\left\{\begin{matrix}1\\\gamma\;1\end{matrix}\right\} - \left\{\begin{matrix}\gamma\\2\;1\end{matrix}\right\}\left\{\begin{matrix}1\\\gamma\;2\end{matrix}\right\}\right]$$

$$= a_{11}\left[\frac{\partial}{\partial v^1}\left(-\frac{(v^1)^2 - a^2}{(v^1)^2}\right) - 0 + \left\{\begin{matrix}1\\2\;2\end{matrix}\right\}\left\{\begin{matrix}1\\1\;1\end{matrix}\right\} + \left\{\begin{matrix}2\\2\;2\end{matrix}\right\}\left\{\begin{matrix}1\\2\;1\end{matrix}\right\}\right.$$

$$\left. - \left\{\begin{matrix}1\\2\;1\end{matrix}\right\}\left\{\begin{matrix}1\\2\;1\end{matrix}\right\} - \left\{\begin{matrix}2\\2\;1\end{matrix}\right\}\left\{\begin{matrix}1\\2\;2\end{matrix}\right\}\right]$$

$$= \frac{(v^1)^2}{(v^1)^2 - a^2}\left[-\frac{2a^2}{(v^1)^3} + \frac{a^2}{(v^1)^3} + \frac{(v^1)^2 - a^2}{(v^1)^3}\right] = \frac{(v^1)^2 - 2a^2}{v^1[(v^1)^2 - a^2]}.$$

The Gaussian curvature K of the surface S_1 is given by

$$K = \frac{R_{1212}}{a} = \frac{(v^1)^2 - 2a^2}{v^1[(v^1)^2 - a^2]}\,\frac{(v^1)^2 - a^2}{(v^1)^4} = \frac{(v^1)^2 - 2a^2}{(v^1)^5} \neq 0.$$

Thus, the surface S_1 is non-developable. Now, the reciprocal tensors for the first fundamental form to S_2 are

$$a^{11} = 1;\quad a^{22} = \frac{1}{a^2 + (u^1)^2};\quad a^{12} = 0 = a^{21}.$$

The non-vanishing Christoffel symbols of first and second kinds are

$$[22;1] = \frac{u^1}{[a^2 + (u^1)^2]^2};\quad [12;2] = -\frac{u^1}{[a^2 + (u^1)^2]^2} = [21;2].$$

$$\left\{\begin{matrix}1\\2\;2\end{matrix}\right\} = \frac{u^1}{[a^2 + (u^1)^2]^2};\quad \left\{\begin{matrix}2\\2\;1\end{matrix}\right\} = -\frac{u^1}{[a^2 + (u^1)^2]^3} = \left\{\begin{matrix}2\\1\;2\end{matrix}\right\}.$$

The Riemann tensor R_{1212} is given by

$$R_{1212} = a_{1}\ R_{212} = a_{11}R^{1}_{212} + a_{12}R^{2}_{212} = a_{11}R^{1}_{212}$$

$$= a_{11}\ \frac{@}{@u^1}\ \genfrac{}{}{0pt}{}{1}{2\ 2}\quad \frac{@}{@u^2}\ \genfrac{}{}{0pt}{}{1}{2\ 1} + \genfrac{}{}{0pt}{}{}{2\ 2}\quad \genfrac{}{}{0pt}{}{1}{1}\quad \genfrac{}{}{0pt}{}{}{2\ 1}\quad \genfrac{}{}{0pt}{}{1}{2}$$

$$= \frac{@}{@u^1}\ \frac{u^1}{[a^2+(u^1)^2]^2}\quad 0 + \genfrac{}{}{0pt}{}{1}{2\ 2}\ \genfrac{}{}{0pt}{}{1}{1\ 1} + \genfrac{}{}{0pt}{}{2}{2\ 2}\ \genfrac{}{}{0pt}{}{1}{2\ 1}$$

$$\genfrac{}{}{0pt}{}{1}{2\ 1}\ \genfrac{}{}{0pt}{}{1}{2\ 1}\quad \genfrac{}{}{0pt}{}{2}{2\ 1}\ \genfrac{}{}{0pt}{}{1}{2\ 2}$$

$$= \frac{a^2 \quad 3(u^1)^2}{[a^2+(u^1)^2]^3} + \frac{(u^1)^2}{[a^2+(u^1)^2]^5}:$$

The Gaussian curvature of the surface S_2 is given by

$$= \frac{R_{1212}}{a} = \frac{a^2 \quad 3(u^1)^2}{[a^2+(u^1)^2]^2} + \frac{(u^1)^2}{[a^2+(u^1)^2]^4} \neq 0:$$

Thus, the surface S_2 is non-developable.

EXAMPLE 6.7.2 Determine whether the surface with the metric $ds^2 = (u^2)^2(du^1)^2 + (u^1)^2(du^2)^2$ is a developable or not?

Solution: From the given metric, we see that $a_{11} = (u^2)^2; a_{22} = (u^1)^2; a_{12} = 0 = a_{21};$ so that $a = (u^1u^2)^2$: Now, the reciprocal tensors a are given by

$$a^{11} = \frac{1}{(u^2)^2};\ a^{22} = \frac{1}{(u^1)^2};\ a^{12} = 0 = a^{21}:$$

The non-vanishing Christoffel symbols of first and second kinds are

$$[11;2] = \quad u^2; [12;1] = u^2 = [21;1]; [12;2] = u^1 = [21;2]; [22;1] = \quad u^1:$$

$$\genfrac{}{}{0pt}{}{1}{2\ 1} = \frac{1}{u^2} = \genfrac{}{}{0pt}{}{1}{1\ 2};\quad \genfrac{}{}{0pt}{}{2}{2\ 1} = \frac{1}{u^1} = \genfrac{}{}{0pt}{}{2}{1\ 2};\quad \genfrac{}{}{0pt}{}{1}{2\ 2} = \frac{u^1}{(u^2)^2}:$$

The Riemann tensor R_{1212} is given by

$$R_{1212} = a_{1}\ R_{212} = a_{11}R^{1}_{212} + a_{12}R^{2}_{212} = a_{11}R^{1}_{212}$$

$$= a_{11}\ \frac{@}{@u^1}\ \genfrac{}{}{0pt}{}{1}{2\ 2}\quad \frac{@}{@u^2}\ \genfrac{}{}{0pt}{}{1}{2\ 1} + \genfrac{}{}{0pt}{}{}{2\ 2}\quad \genfrac{}{}{0pt}{}{1}{1}\quad \genfrac{}{}{0pt}{}{}{2\ 1}\quad \genfrac{}{}{0pt}{}{1}{2}$$

$$= (u^2)^2\ \frac{@}{@u^1}\ \frac{u^1}{(u^2)^2}\quad \frac{@}{@u^2}\ \frac{1}{u^2} + \genfrac{}{}{0pt}{}{1}{2\ 2}\ \genfrac{}{}{0pt}{}{1}{1\ 1} + \genfrac{}{}{0pt}{}{2}{2\ 2}\ \genfrac{}{}{0pt}{}{1}{2\ 1}$$

$$\genfrac{}{}{0pt}{}{1}{2\ 1}\ \genfrac{}{}{0pt}{}{1}{2\ 1}\quad \genfrac{}{}{0pt}{}{2}{2\ 1}\ \genfrac{}{}{0pt}{}{1}{2\ 2} = (u^2)^2 \quad 0 = 0:$$

The Gaussian curvature κ for the given surface is given by

$$\kappa = \frac{R_{1212}}{a} = \frac{0}{(u^1u^2)^2} = 0.$$

Thus, the surface is developable.

EXAMPLE 6.7.3 Show that the surface given by $x^1 = f_1(u^1)$; $x^2 = f_2(u^1)$; $x^3 = u^2$ is a developable, where f_1, f_2 are differentiable functions.

Solution: The first fundamental forms for the given surfaces are given by

$$a_{11} = \left(\frac{\partial x^i}{\partial u^1}\right)^2 = \left(\frac{\partial x^1}{\partial u^1}\right)^2 + \left(\frac{\partial x^2}{\partial u^1}\right)^2 + \left(\frac{\partial x^3}{\partial u^1}\right)^2 = (f_1')^2 + (f_2')^2.$$

$$a_{22} = \left(\frac{\partial x^i}{\partial u^2}\right)^2 = \left(\frac{\partial x^1}{\partial u^2}\right)^2 + \left(\frac{\partial x^2}{\partial u^2}\right)^2 + \left(\frac{\partial x^3}{\partial u^2}\right)^2 = 1.$$

$$a_{12} = \frac{\partial x^1}{\partial u^1}\frac{\partial x^1}{\partial u^2} + \frac{\partial x^2}{\partial u^1}\frac{\partial x^2}{\partial u^2} + \frac{\partial x^3}{\partial u^1}\frac{\partial x^3}{\partial u^2} = 0 = a_{21}.$$

Therefore, $a = (f_1')^2 + (f_2')^2$. The reciprocal tensors are given by

$$a^{11} = \frac{1}{(f_1')^2 + (f_2')^2};\ a^{22} = 1;\ a^{12} = 0 = a^{21}.$$

The only non-vanishing Christoffel symbols of first kind and second kinds are

$$[11, 1] = f_1'f_1'' + f_2'f_2'';\quad \left\{ {1 \atop 1\ 1} \right\} = \frac{f_1'f_1'' + f_2'f_2''}{(f_1')^2 + (f_2')^2}.$$

The Riemann tensor R_{1212} is given by

$$\begin{aligned} R_{1212} &= a_{1\alpha}R^{\alpha}_{212} = a_{11}R^1_{212} + a_{12}R^2_{212} = a_{11}R^1_{212} \\ &= a_{11}\left[\frac{\partial}{\partial u^1}\left\{ {1 \atop 2\ 2} \right\} - \frac{\partial}{\partial u^2}\left\{ {1 \atop 2\ 1} \right\} + \left\{ {\alpha \atop 2\ 2} \right\}\left\{ {1 \atop \alpha\ 1} \right\} - \left\{ {\alpha \atop 2\ 1} \right\}\left\{ {1 \atop \alpha\ 2} \right\}\right] \\ &= a_{11}\left[\frac{\partial}{\partial u^1}0 - \frac{\partial}{\partial u^2}0 + \left\{ {1 \atop 2\ 2} \right\}\left\{ {1 \atop 1\ 1} \right\} + \left\{ {2 \atop 2\ 2} \right\}\left\{ {1 \atop 2\ 1} \right\} \right. \\ &\quad \left. - \left\{ {1 \atop 2\ 1} \right\}\left\{ {1 \atop 1\ 2} \right\} - \left\{ {2 \atop 2\ 1} \right\}\left\{ {1 \atop 2\ 2} \right\}\right] = 0. \end{aligned}$$

The Gaussian curvature κ for the given surface is given by

$$\kappa = \frac{R_{1212}}{a} = \frac{0}{(f_1')^2 + (f_2')^2} = 0.$$

Thus, the surface is developable.

6.8 Geodesic Curvature

In this section we will describe the geodesic curvature of surface curves on a surface S of class 2. Here, using the intrinsic geometry of surfaces we will derive a formula describing the behaviour of the tangent vector to a surface curve. Let C be a surface curve given by a parametric representation

$$C: u \quad = u \quad (s); \qquad (6.58)$$

where s measures arc distance along the curve C. Then, at an arbitrary point P of the curve, we have the condition

$$a \quad \frac{du}{ds}\frac{du}{ds} = 1: \qquad (6.59)$$

The quantities $\frac{du^1}{ds}; \frac{du^2}{ds}$ obviously determine a tangent vector to C, and so writing the unit values for $\frac{du}{ds}$ we have from Eq. (6.59) that

$$a \quad \frac{du}{ds}\frac{du}{ds} = a \qquad = 1: \qquad (6.60)$$

Differentiate the quadratic relation (6.60) intrinsically with respect to s, we get

$$a \qquad \frac{\quad}{s} = 0$$

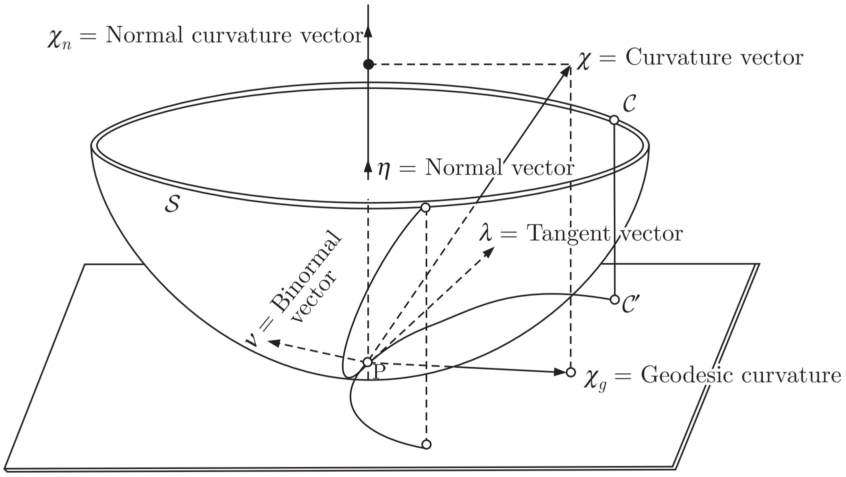
from which it follows that either the surface vector $\frac{\quad}{s}$ is orthogonal to or $\frac{\quad}{s} = 0$. If $\frac{\quad}{s} \neq 0$, we introduce a unit surface vector normal to (codirectional with $\frac{\quad}{s}$), (Figure 6.14), so that

$$\frac{\quad}{s} = {}_g \quad ; \qquad (6.61)$$

where $_g$ is a suitable scalar, positive or negative. We choose the sense of such that the rotation (;) is positive, i.e. = 1. The scalar $_g$ is called the geodesic curvature of the curve C on the surface. The geodesic curvature was introduced by Lionville.

(i) Now we give the geometrical significance of the geodesic curvature $_g$. Let C^0 be the orthogonal projection of C on the tangent plane to S at P (Figure 6.14). The geodesic curvature $_g$ of C at P is defined as the curvature of the projected curve C at P, taken with a suitable sign.

(ii) The sign of $_g$ is defined as follows: Suppose that the curvature of C^0 at P is not zero. Then $_g$ is positive sign if the centre of curvature C^0 at P lies in the direction of the unit vector = , where is the unit normal vector to S at P and is the tangent vector to C at P. $_g$ is negative sign if that centre of curvature lies in the direction opposite to the vector . The sign of $_g$ thus depends on the orientations of S and C. (In Figure 6.14 , $_g$ is negative).



χ_n = Normal curvature vector
χ = Curvature vector
$\mathcal{C}$
η = Normal vector
$\mathcal{S}$
λ = Tangent vector
ν = Binormal vector
$\mathcal{C}'$
P
χ_g = Geodesic curvature

Figure 6.14: Geodesic curvature.

Since = " and = " , taking the intrinsic derivative, we get

$$\frac{\quad}{s} = " \; \frac{\quad}{s} = " \; \frac{\quad}{s} \; a$$

$$= " \; a \; \frac{\quad}{s} = " \; a \quad {}_g$$

or

$$\frac{\quad}{s} = {}_g" \qquad = {}_g" \qquad = {}_g$$

or

$$\frac{\quad}{s} = {}_g \; : \qquad (6.62)$$

We may refer this pair of Eqs. (6.61) and (6.62) as the Serret{Frenet formulae for the curve C relative to the surface. The transversion of $\frac{\quad}{s}$ = $_g$ by , we get

$${}_g = \frac{\quad}{s} = \frac{\quad}{s} \; " \qquad = " \qquad \frac{\quad}{s}$$

$$= \frac{1}{\sqrt{a}} e \qquad \frac{\quad}{s} = \frac{1}{\sqrt{a}} \; \begin{matrix} ^1 & ^2 \\ \frac{^1}{s} & \frac{^2}{s} \end{matrix} \; :$$

Alternatively, using $\frac{\quad}{s} = \ _g$; we get

$$ {}_g = " \quad \frac{\quad}{s} = \frac{1}{\sqrt{a}} \begin{array}{cc} {}^1 & {}^2 \\ {}^1 & {}^2 \\ \frac{\quad}{s} & \frac{\quad}{s} \end{array} $$

$$ = \sqrt{a} \begin{array}{cc} \frac{du^1}{ds} & \frac{du^2}{ds} \\ \frac{d^2u^1}{ds^2} + \ {}^1 \ \frac{du}{ds}\frac{du}{ds} & \frac{d^2u^2}{ds^2} + \ {}^2 \ \frac{du}{ds}\frac{du}{ds} \end{array} : \tag{6.63} $$

These expressions are known as Beltrami's formula for geodesics curvature.

Theorem 6.8.1 The necessary and sufficient condition for a curve on a surface to be a geodesic is that its geodesic curvature is zero.

Proof: The differential equation of the geodesic is

$$ \frac{d^2u}{ds^2} + \qquad \frac{du}{ds}\frac{du}{ds} = 0 $$

or

$$ \frac{d}{ds} \ \frac{du}{ds} \ + \qquad \frac{du}{ds}\frac{du}{ds} = 0 $$

or

$$ \frac{@}{@u} \ \frac{du}{ds} \ \frac{du}{ds} + \qquad \frac{du}{ds}\frac{du}{ds} = 0 $$

or

$$ \frac{@}{@u} \ \frac{du}{ds} \ + \qquad \frac{du}{ds} \ \frac{du}{ds} = 0 $$

or

$$ \frac{du}{ds} {}_{;} \ \frac{du}{ds} = 0 : $$

According to the intrinsic derivative of a tensor of type $(1;0)$ with component u , the above relation becomes

$$ \frac{\quad}{s} \ \frac{du}{ds} \ = 0 \ ) \ \frac{\quad}{s} \ = 0 $$

$$) \quad {}_g \ = 0; \text{ as } \frac{\quad}{s} = \ {}_g $$

$$) \quad {}_g = 0 \text{ as } \quad \text{is a unit vector.} $$

Hence, the curve on a surface is to be a geodesic if the geodesic curvature is zero.

Conversely, let ${}_g = 0$, identically, then we have

$$\frac{}{s}\frac{du}{ds} = \frac{}{s} = {}_g = 0$$

$$) \; \frac{du}{ds} = A \;) \; u = As + B:$$

This shows that, a geodesic of a surface is, therefore, analogous to a straight line in a plane. Therefore, a curve C on a surface S is a geodesic curve or geodesic if its geodesic curvature ${}_g$ vanishes identically. Straight lines on any surface are geodesics.

EXAMPLE 6.8.1 Find the geodesic curvature of the small circle

$$C: u^1 = \text{constant} = u^1_0 \, 6{=}\, 0; u^2 = u^2$$

on the surface of the sphere S.

Solution: On the surface of sphere

$$S: y^1 = a \cos u^1 \cos u^2; y^2 = a \cos u^1 \sin u^2; y^3 = a \sin u^1:$$

If the arc length s of C is measured from the plane $u_2 = 0$, we have $u^2 = \frac{s}{a \cos u^1_0}$, and the equation of C can be written in the form

$$u^1 = u^1_0; \quad u^2 = \frac{s}{a \cos u^1_0};$$

whose metric is $ds^2 = a^2 \; du^1 \;{}^2 + a^2 \; \cos u^1 \;{}^2 \; du^2 \;{}^2$; where the metric coefficients of s are $a_{11} = a^2; a_{12} = 0$ and $a_{22} = a^2 \cos^2 u^1$. The components of the unit tangent vector $= \frac{du}{ds}$ along C are given by

$$= {}^1; {}^2 = \frac{du^1}{ds}; \frac{du^2}{ds} = 0; \frac{1}{a \cos u^1_0} :$$

The only non-vanishing Christoffel symbols are

$$\begin{matrix}1\\2\;2\end{matrix} = a^{11}[22;1] = \frac{1}{a^{11}}\frac{@a_{22}}{@u^1} = \cos u^1_0 \sin u^1_0$$

$$\begin{matrix}2\\1\;2\end{matrix} = a^{22}[12;2] = \frac{1}{a^{22}}\frac{@a_{22}}{@u^1} = \tan u^1_0 = \begin{matrix}2\\2\;1\end{matrix} :$$

Using the definition of intrinsic derivative, we get

$$\frac{\delta\lambda^1}{\delta s} = \frac{d\lambda^1}{ds} + \Gamma^1_{\alpha\beta}\lambda^\alpha\frac{du^\beta}{ds} = \frac{d\lambda^1}{ds} + \Gamma^1_{11}\lambda^1\frac{du^1}{ds} + \Gamma^1_{12}\lambda^1\frac{du^2}{ds}$$

$$+\Gamma^1_{21}\lambda^2\frac{du^1}{ds} + \Gamma^1_{22}\lambda^2\frac{du^2}{ds} = \Gamma^1_{22}\lambda^2\lambda^2$$

$$\frac{\delta\lambda^2}{\delta s} = \frac{d\lambda^2}{ds} + \Gamma^2_{\alpha\beta}\lambda^\alpha\frac{du^\beta}{ds} = 0 + \Gamma^2_{22}\lambda^2\lambda^2$$

Using the formula (6.62) we get

$$\kappa_g\eta^1 = \frac{\delta\lambda^1}{\delta s} = \Gamma^1_{22}\lambda^2\lambda^2 = \cos u^1_0\sin u^1_0\left(\frac{1}{a\cos u^1_0}\right)^2 = \frac{1}{a^2}\tan u^1_0$$

$$\kappa_g\eta^2 = \Gamma^2_{22}\lambda^2\lambda^2 = 0.$$

Since C is not a geodesic, $\kappa_g \neq 0$ and we conclude that $\eta^2 = 0$. But η^2 is a unit vector so that $a_{\alpha\beta}\eta^\alpha\eta^\beta = 1$, i.e.

$$a_{11}\eta^1\eta^1 + 2a_{12}\eta^1\eta^2 + a_{22}\eta^2\eta^2 = 1$$

or

$$a^2\eta^1\eta^1 = 1 \Rightarrow \eta^1 = \frac{1}{a}.$$

Here κ_g is given by

$$\kappa_g = \frac{1}{\eta^1}\frac{1}{a^2}\tan u^1_0 = \frac{1}{a}\tan u^1_0.$$

Hence, the geodesic curvature is $\frac{1}{a}\tan u^1_0$.

EXAMPLE 6.8.2 Consider the surface of the right circular cone

$$C: x^1 = u^1\cos u^2;\ x^2 = u^1\sin u^2;\ x^3 = u^1;$$

where $u^1; u^2$ are the curvilinear co-ordinates on S and the curve C whose equation taken in the form $C: u^1 = a; u^2 = \frac{s}{a}$; where s is the arc parameter. Show that $\kappa_g = \frac{\sqrt{2}}{2\sqrt{a}}$.

Solution: Here, the metric is given by

$$ds^2 = 2\left(du^1\right)^2 + \left(u^1\right)^2\left(du^2\right)^2;$$

where the metric coefficients of S are $a_{11} = 2; a_{22} = \ u^1\ ^2; a_{33} = 0$ and $a_{12} = 0$ so that $a = 2\ u^1\ ^2$: The conjugate tensors are given by

$$a^{11} = \frac{1}{a_{11}} = 2; a^{22} = \frac{1}{(u^1)^2} \text{ and } a^{33} = 0;\ a^{12} = 0 = a^{21}:$$

The only non-vanishing Christoffel symbols of second kind are

$$\begin{matrix}1\\2\ 2\end{matrix} = \frac{1}{2a_{11}}\frac{@a_{22}}{@u^1} = \ u^1 = \ a:$$

Now, the components of the unit tangent vector $= \frac{du}{ds}$ along C are given by

$$= \ ^1;\ \ ^2 = \frac{du^1}{ds}; \frac{du^2}{ds} = \ 0; \frac{1}{a} \ :$$

Using the definition of intrinsic derivative, we get

$$\frac{\ ^1}{s} = \frac{d\ ^1}{ds} + \ \ 1 \ \ \frac{du}{ds}$$

$$= \frac{d\ ^1}{ds} + \begin{matrix}1\\1\ 1\end{matrix}\ {}_1\frac{du^1}{ds} + \begin{matrix}1\\2\ 2\end{matrix}\ {}_2\frac{du^2}{ds} + \begin{matrix}1\\2\ 1\end{matrix}\ {}_2\frac{du^1}{ds} + \begin{matrix}1\\1\ 2\end{matrix}\ {}_1\frac{du^2}{ds}$$

$$= \begin{matrix}1\\2\ 2\end{matrix}\ {}_2\frac{du^2}{ds} = \ \frac{1}{2a}$$

$$\frac{\ ^2}{s} = \frac{d\ ^2}{ds} + \ \ 2 \ \ \frac{du}{ds}$$

$$= \frac{d\ ^2}{ds} + \begin{matrix}2\\1\ 1\end{matrix}\ {}_1\frac{du^1}{ds} + \begin{matrix}2\\2\ 2\end{matrix}\ {}_2\frac{du^2}{ds} + \begin{matrix}2\\1\ 2\end{matrix}\ {}_2\frac{du^1}{ds} + \begin{matrix}2\\2\ 1\end{matrix}\ {}_1\frac{du^2}{ds} = 0:$$

Using formula (6.62), we get

$$_g\ ^1 = \frac{\ ^1}{s} = \ \frac{1}{2a} \text{ and } _g\ ^2 = \frac{\ ^2}{s} = 0:$$

Since C is not a geodesic $_g \neq 0$ and we conclude that $^2 = 0$. But ^{2} is a unit vector so that a $= 1$, i.e.

$$a_{11}\ ^1\ ^1 + a_{22}\ ^2\ ^2 + 2a_{12}\ ^1\ ^2 = 1$$

or

$$2\ \ ^1\ ^2 + \ u^1\ ^2\ \ ^2\ ^2 = 1 \ )\ \ ^1\ ^2 = \frac{1}{2}$$

$$)\ \ _g = \frac{1}{\ _1}\ \ \frac{1}{2a} = \ \frac{1}{\sqrt{2}}\frac{1}{2a} = \ \frac{1}{a2\sqrt{2}}:$$

EXAMPLE 6.8.3 Show that the geodesic curvature of the curve $u = c$ on a surface with metric $\lambda^2(du)^2 + \mu^2(dv)^2$ is $\frac{1}{\lambda\mu}\frac{\partial\mu}{\partial u}$.

Solution: For the given metric $ds^2 = \lambda^2(du)^2 + \mu^2(dv)^2$; the metric coefficients are $a_{11} = \lambda^2; a_{22} = \mu^2$ and $a_{12} = 0$ and so, $a = \lambda^2\mu^2$. Thus, the conjugate tensors are given by

$$a^{11} = \frac{a_{22}}{a} = \frac{1}{\lambda^2};\ a^{22} = \frac{a_{11}}{a} = \frac{1}{\mu^2};\ a^{12} = 0 = a^{21}.$$

The Christoffel symbols of first kind are

$$[11;1] = \frac{1}{2}\frac{\partial a_{11}}{\partial u^1} = \lambda\frac{d\lambda}{du};\ [22;2] = \frac{1}{2}\frac{\partial a_{22}}{\partial u^2} = \mu\frac{d\mu}{dv}$$

$$[11;2] = \frac{1}{2}\left(\frac{\partial a_{12}}{\partial u^1} + \frac{\partial a_{12}}{\partial u^1} - \frac{\partial a_{11}}{\partial u^2}\right) = -\lambda\frac{d\lambda}{dv}$$

$$[21;1] = \frac{1}{2}\left(\frac{\partial a_{21}}{\partial u^1} + \frac{\partial a_{11}}{\partial u^2} - \frac{\partial a_{21}}{\partial u^1}\right) = \frac{1}{2}\frac{\partial a_{11}}{\partial u^2} = \lambda\frac{d\lambda}{dv} = [12;1]$$

$$[22;1] = \frac{1}{2}\left(\frac{\partial a_{21}}{\partial u^2} + \frac{\partial a_{21}}{\partial u^2} - \frac{\partial a_{22}}{\partial u^1}\right) = -\frac{1}{2}\frac{\partial a_{22}}{\partial u^1} = -\mu\frac{d\mu}{du}$$

$$[12;2] = \frac{1}{2}\left(\frac{\partial a_{12}}{\partial u^2} + \frac{\partial a_{22}}{\partial u^1} - \frac{\partial a_{12}}{\partial u^2}\right) = \frac{1}{2}\frac{\partial a_{22}}{\partial u^1} = \mu\frac{d\mu}{du} = [21;2].$$

The Christoffel symbols of second kind are

$$\left\{ {1 \atop 1\ 1} \right\} = a^{1k}[11;k] = a^{11}[11;1] = \frac{1}{\lambda}\frac{d\lambda}{du}$$

$$\left\{ {1 \atop 2\ 1} \right\} = a^{1k}[21;k] = a^{11}[21;1] + a^{12}[21;2] = \frac{1}{\lambda}\frac{d\lambda}{dv} = \left\{ {1 \atop 1\ 2} \right\}$$

$$\left\{ {1 \atop 2\ 2} \right\} = a^{1k}[22;k] = a^{11}[22;1] + a^{12}[22;2] = -\frac{\mu}{\lambda^2}\frac{d\mu}{du}$$

$$\left\{ {2 \atop 2\ 1} \right\} = a^{2k}[21;k] = a^{21}[21;1] + a^{22}[21;2] = \frac{1}{\mu}\frac{d\mu}{du} = \left\{ {2 \atop 1\ 2} \right\}$$

$$\left\{ {2 \atop 2\ 2} \right\} = a^{2k}[22;k] = a^{21}[22;1] + a^{22}[22;2] = \frac{1}{\mu}\frac{d\mu}{dv}$$

$$\left\{ {2 \atop 1\ 1} \right\} = a^{2k}[11;k] = a^{21}[11;1] + a^{22}[11;2] = -\frac{\lambda}{\mu^2}\frac{d\lambda}{dv}$$

Let $_g$ be the geodesic curvature, then from Beltrami's formula (6.63), we have

$$
\begin{aligned}
{}_g &= \sqrt{a}\,\Bigg[\frac{du^1}{ds}\,\frac{d^2u}{ds^2} + \genfrac{}{}{0pt}{}{2}{}\,\frac{du}{ds}\,\frac{du}{ds}\qquad \frac{du^2}{ds}\,\frac{d^2u}{ds^2} + \genfrac{}{}{0pt}{}{1}{}\,\frac{du}{ds}\,\frac{du}{ds}\Bigg)\\
&= \sqrt{a}\,\frac{du}{ds}\,\frac{d^2v}{ds^2} + \genfrac{}{}{0pt}{}{2}{1\;1}\,\frac{du}{ds}^{2} + \genfrac{}{}{0pt}{}{2}{2\;2}\,\frac{dv}{ds}^{2} + 2\genfrac{}{}{0pt}{}{2}{1\;2}\,\frac{du}{ds}\frac{dv}{ds}\\
&\qquad \frac{dv}{ds}\,\frac{d^2u}{ds^2} + \genfrac{}{}{0pt}{}{1}{1\;1}\,\frac{du}{ds}^{2} + \genfrac{}{}{0pt}{}{1}{2\;2}\,\frac{dv}{ds}^{2} + 2\genfrac{}{}{0pt}{}{1}{1\;2}\,\frac{du}{ds}\frac{dv}{ds}\Bigg)\Bigg]
\end{aligned}
$$

Since for the v parametric curve, $u = c =$ constant, so,

$$
\begin{aligned}
{}_g &= \sqrt{a}\,\frac{dv}{ds}\,\genfrac{}{}{0pt}{}{1}{2\;2}\,\frac{dv}{ds}^{2} = \sqrt{a}\,\genfrac{}{}{0pt}{}{1}{2\;2}\,\frac{dv}{ds}^{3}\\
&= \sqrt{a}\,\genfrac{}{}{0pt}{}{1}{2\;2}\,\frac{1}{a_{22}\sqrt{a_{22}}};\ \text{as}\ \frac{dvdv}{ds^2} = \frac{dvdv}{a_{22}dvdv} = \frac{1}{a_{22}}\\
&= \frac{1}{2}\frac{\partial}{\partial u}(\ ^2)\qquad \frac{1}{\ ^3} = \frac{1}{\ }\frac{\partial}{\partial u}.
\end{aligned}
$$

EXAMPLE 6.8.4 Show that the condition that the parametric curves u^1 and u^2 on a portion of a surface be geodesic are respectively

$$\genfrac{}{}{0pt}{}{2}{1\;1} = 0 \ \text{and}\ \genfrac{}{}{0pt}{}{1}{2\;2} = 0.$$

Solution: Let $^{(1)}_g$ and $^{(2)}_g$ be the geodesic curvatures of the u^1 and u^2 parametric curves, respectively. Then from Beltrami's formula (6.63), we get

$$
\begin{aligned}
{}^{(1)}_g &= \sqrt{a}\,\Bigg[\frac{du^1}{ds}\,\frac{d^2u^2}{ds^2} + \genfrac{}{}{0pt}{}{2}{1\;1}\,\frac{du^1}{ds}^{2} + \genfrac{}{}{0pt}{}{2}{2\;2}\,\frac{du^2}{ds}^{2} + 2\genfrac{}{}{0pt}{}{2}{1\;2}\,\frac{du^1}{ds}\frac{du^2}{ds}\Bigg)\\
&\qquad \frac{du^2}{ds}\,\frac{d^2u^1}{ds^2} + \genfrac{}{}{0pt}{}{1}{1\;1}\,\frac{du^1}{ds}^{2} + \genfrac{}{}{0pt}{}{1}{2\;2}\,\frac{du^2}{ds}^{2} + 2\genfrac{}{}{0pt}{}{1}{1\;2}\,\frac{du^1}{ds}\frac{du^2}{ds}\Bigg)\Bigg] .
\end{aligned}
$$

Since for the u^1 parametric curve, $u^2 = c_1 =$ constant, so,

$$
\begin{aligned}
{}^{(1)}_g &= \sqrt{a}\,\frac{du^1}{ds}\,\genfrac{}{}{0pt}{}{2}{1\;1}\,\frac{du^1}{ds}^{2} = \sqrt{a}\,\genfrac{}{}{0pt}{}{2}{1\;1}\,\frac{du^1}{ds}^{3}\\
&= \sqrt{a}\,\genfrac{}{}{0pt}{}{2}{1\;1}\,\frac{1}{a_{11}\sqrt{a_{11}}};\ \text{as}\ \frac{du^1du^1}{ds^2} = \frac{du^1du^1}{a_{11}du^1du^1} = \frac{1}{a_{11}}.
\end{aligned}
$$

Similarly, for the u^2 parametric curve, $u^1 = c_2$ = constant, so,

$$\kappa_g^{(2)} = -\sqrt{a}\left\{\begin{matrix}1\\2\;2\end{matrix}\right\}\frac{1}{a_{22}\sqrt{a_{22}}}.$$

We can derive these results by using the formula

$$\kappa_g = \varepsilon_{\alpha\beta}\lambda^{\alpha}\frac{\delta\lambda^{\beta}}{\delta s};\quad \text{where } \lambda_{(1)} = \left(\frac{1}{\sqrt{a_{11}}}, 0\right) \text{ and } \lambda_{(2)} = \left(0, \frac{1}{\sqrt{a_{22}}}\right).$$

If the geodesic curvature vanishes identically, then the curve is a geodesic. Thus, from the relations

$$\kappa_g^{(1)} = \sqrt{a}\left\{\begin{matrix}2\\1\;1\end{matrix}\right\}\frac{1}{a_{11}\sqrt{a_{11}}} \text{ and } \kappa_g^{(2)} = -\sqrt{a}\left\{\begin{matrix}1\\2\;2\end{matrix}\right\}\frac{1}{a_{22}\sqrt{a_{22}}}$$

we get that parametric curves are geodesic if and only if

$$\left\{\begin{matrix}2\\1\;1\end{matrix}\right\} = 0 \text{ and } \left\{\begin{matrix}1\\2\;2\end{matrix}\right\} = 0;\ \text{as } a = |a_{\alpha\beta}| \neq 0.$$

EXAMPLE 6.8.5 Show that the condition that the parametric curves on a portion of a surface

$$\mathbf{r} = (c\cos u^2\cos u^1, c\cos u^2\sin u^1, c\sin u^2)$$

be geodesic.

Solution: In the representation of the sphere $\mathbf{r}(u^1, u^2)$, the co-ordinates u^1, u^2 are orthogonal. We have

$$a_{11} = c^2\cos^2 u^2;\ a_{22} = c^2;\ \frac{\partial a_{22}}{\partial u^1} = 0;\ \text{and } a_{12} = 0 = a_{21}.$$

Therefore, the Christoffel symbol $\left\{\begin{matrix}1\\2\;2\end{matrix}\right\}$ is given by

$$\begin{aligned}\left\{\begin{matrix}1\\2\;2\end{matrix}\right\} &= \frac{1}{2a}\left[a_{22}\left(2\frac{\partial a_{12}}{\partial u^2} - \frac{\partial a_{22}}{\partial u^1}\right) - a_{12}\frac{\partial a_{22}}{\partial u^2}\right]\\ &= \frac{1}{2c^4\cos^2 u^2}\left[c^2(2\cdot 0 - 0) - 0\cdot 0\right] = 0\end{aligned}$$

that is, the curves u^1 = constant are geodesics. Now,

$$\begin{aligned}\left\{\begin{matrix}2\\1\;1\end{matrix}\right\} &= \frac{1}{2a}\left[a_{11}\left(2\frac{\partial a_{12}}{\partial u^1} - \frac{\partial a_{11}}{\partial u^2}\right) - a_{12}\frac{\partial a_{11}}{\partial u^1}\right]\\ &= \frac{1}{2c^4\cos^2 u^2}\left[c^2\cos^2 u^2(2\cdot 0 + 2c^2\cos u^2\sin u^2) - 0\cdot 0\right]\\ &= \cos u^2\sin u^2 = 0;\ \text{if } u^2 = 0\end{aligned}$$

that is, along the equator which is the only geodesic of the curves u^2 = constant. At the poles $u^2 = \pm\frac{\pi}{2}$ and also $\Gamma^2_{11} = 0$ but

$$x^1 = c\cos u^2 \cos u^1;\ x^2 = c\cos u^2 \sin u^1;\ x^3 = c\sin u^2:$$

is not valid at these points. Furthermore we see from

$$(\kappa_g)_{u^1=\text{constant}} = \frac{1}{\sqrt{a_{11}}}\frac{\partial}{\partial u^1}(\log\sqrt{a_{22}})$$
$$(\kappa_g)_{u^2=\text{constant}} = -\frac{1}{\sqrt{a_{22}}}\frac{\partial}{\partial u^2}(\log\sqrt{a_{11}})$$

that the co-ordinate curves of orthogonal co-ordinates are geodesics if and only if a_{11} does not depend on u^2 and a_{22} does not depend on u^1.

6.9 Exercises

1. On the surface of revolution $r = (u\cos\theta; u\sin\theta; f(u))$ what are the parametric curves for u = constant and what are the curves θ = constant.
2. On the right helicoid given by $r = (u\cos\theta; u\sin\theta; c\theta)$; show that the parametric curves are circular helices and straight lines.
3. On the hyperboloid of one sheet

   $$\frac{x}{a} = \frac{\sigma+\tau}{1+\sigma\tau};\ \frac{y}{b} = \frac{1-\sigma\tau}{1+\sigma\tau};\ \frac{z}{c} = \frac{\sigma-\tau}{1+\sigma\tau};$$

   the parametric curves are the generators. What curves are represented by $\sigma = \tau$ and by $\sigma\tau$ = constant?
4. What types of surface are determined by the following representations:
   (a) $r = (x^1; x^2; x^3) = (0; u^1; u^2)$;
   (b) $r = (x^1; x^2; x^3) = (u^1 + u^2; u^1 + u^2; u^1)$;
   (c) $r = (x^1; x^2; x^3) = (a\cos u^1; a\sin u^1; u^2)$:
   Investigate the behaviour of the corresponding matrices and find representation of the form (6.1).
5. Find a parametric representation of the cylinder generated by a straight line G which moves along a curve.

   $$C: x(s) = (h_1(s); h_2(s); h_3(s))$$

   and is parallel to the x^3 axis; consider the corresponding matrix.

6. Find a representation of the form (6.1) of the following surfaces
   - (a) Ellipsoid: $r = (a\cos u^2 \cos u^1; b\cos u^2 \sin u^1; c\sin u^2)$:
   - (b) Elliptic paraboloid: $r = (au^1 \cos u^2; bu^1 \sin u^2; (u^1)^2))$:
   - (c) Hyperbolic paraboloid : $r = (au^1 \cosh u^2; bu^1 \sinh u^2; (u^1)^2)$:
   - (d) Hyperboloid of two sheets : $r = (a\sinh u^1 \cos u^2; b\sinh u^1 \sin u^2; c\cosh u^1)$:

   What kind of co-ordinate curves do you have in each case?

7. Show that the first fundamental form for
   - (a) the surface $x^1 = a\cos u^1; x^2 = a\sin u^1; x^3 = u^2$ is given by

     $$ds^2 = a^2(du^1)^2 + (du^2)^2:$$

   - (b) the surface $x^1 = u^1 \cos u^2;\ x^2 = u^1 \sin u^2;\ x^3 = 0$ is given by

     $$ds^2 = (du^1)^2 + (u^1)^2(du^2)^2:$$

   - (c) the surface $x^1 = c\cos u^1 \sin u^2;\ x^2 = c\sin u^1 \sin u^2;\ x^3 = c\cos u^2$ is given by

     $$ds^2 = c^2 \sin^2 u^2(du^1)^2 + c^2 \cos^2 u^2(du^2)^2:$$

   - (d) the surface of revolution $x^1 = u^1 \cos u^2;\ x^2 = u^1 \sin u^2;\ x^3 = f(u^1)$ is given by

     $$ds^2 = (1 + f_1^2)(du^1)^2 + (u^1)^2(du^2)^2:$$

   - (e) the paraboloid $x^1 = u^1; x^2 = u^2;\ x^3 = (u^1)^2 - (u^2)^2$ is given by

     $$ds^2 = [1 + 4(u^1)^2](du^1)^2 - 4u^1u^2du^1du^2 + [1 + 4(u^2)^2](du^2)^2:$$

   - (f) the sphere $x^1 = c\cos u^1 \cos u^2; x^2 = c\cos u^1 \sin u^2; x^3 = c\sin u^1$ is given by

     $$ds^2 = c^2(du^1)^2 + c^2 \cos^2 u^1(du^2)^2:$$

   - (g) a plane with respect to polar co-ordinates.

8. Prove that on the surface given by

   $$x^1 = a(u^1 + u^2);\ x^2 = b(u^1 - u^2);\ x^3 = u^1u^2$$

   the parametric curves are straight lines.

9. Determine the first fundamental form of the cylinder

$$r = (x^1; x^2; x^3) = h_1(u^1); h_2(u^1); u^2$$

and of a cylinder of revolution.

10. Prove that at regular points of a surface the first fundamental form is positive definite.

11. If be the angle between the parametric curves lying on a surface, immersed in E_3, show that

$$\sin = \frac{\sqrt{a}}{\sqrt{a_{11}}\sqrt{a_{22}}} \text{ and } \tan = \frac{\sqrt{a}}{a_{12}}$$

and hence, show that the parametric curves on a surface are orthogonal if and only if $a_{12} = 0$:

12. Show that the area of the anchor ring

$$r = ((b + a\cos u)\cos v; (b + a\cos u)\sin v; a\sin v)$$

where $0 < u < 2;\ 0 < v < 2$ is $4\,{}^2ab$:

13. Prove that a necessary and sufficient condition that a surface S be isometric with the Euclidean plane is that the Riemann tensor (or the Gaussian curvature of S) be identically zero.

14. (a) Prove that " and " can be obtained from the other by raising or lowering of indices with the help of the metric tensors.
    (b) If ; are two unit vectors the rotation ; is positive, show that

$$\sin = " \quad :$$

    (c) If ; are two parallel vector fields, show that " remains constant.

15. Prove that the vector obtained by parallel propagation of the tangent vector to a geodesic always remains tangent to the geodesic.

16. Find the differential equations of the geodesic in (i) Rectangular co-ordinates; (ii) Spherical co-ordinates; (iii) Cylindrical co-ordinates.

17. Show that an elliptic helix is not in general a geodesic on an elliptic cylinder.

18. Show that the differential equations of the geodesic for

(a) the metric $ds^2 = (dx^1)^2 + [(x^1)^2 + c^2](dx^2)^2$ are

$$\frac{d^2x^1}{ds^2} \quad x^1 \quad \frac{dx^2}{ds} \quad ^2 = 0; \ \frac{d^2x^2}{ds^2} + \frac{2x^1}{(x^1)^2 + c^2}\frac{dx^1}{ds}\frac{dx^2}{ds} = 0:$$

(b) the metric $ds^2 = (du)^2 + (\sin u)^2(dv)^2$ are

$$\frac{d^2u}{ds^2} \quad \sin u \cos u \quad \frac{dv}{ds} \quad ^2 = 0; \ \frac{d^2v}{ds^2} + 2 \cot u \frac{du}{ds}\frac{dv}{ds} = 0:$$

19. Obtain the differential equations of geodesics for metric
    (i) $ds^2 = f(x)dx^2 + dy^2 + dz^2 + \frac{1}{f(x)}dt^2$:
    (ii) $ds^2 = e^{2kt} \ dx^2 + dy^2 + dz^2 \ + dt^2$:

20. Show that the geodesics of a sphere of radius a is determined by the equation

$$y^1 = a \cos u^1 \cos u^2; \ y^2 = a \cos u^1 \sin u^2; \ y^3 = a \sin u^1;$$

are great circles, i.e. the great circles on sphere are geodesics.

21. Determine the components of curvature tensors
    (i) of a surface of revolution $r = (u^2 \cos u^1; u^2 \sin u^1; f(u^2))$;
    (ii) of a right conoid $r = (u^2 \cos u^1; u^2 \sin u^1; f(u^1))$;
    (iii) of a surface represented in the form $x_3 = f(x_1; x_2)$.

22. On the surface generated by the tangents to a twisted curve, find the differential equation of the curves which cut the generators at a constant angle .

23. If v are geodesic co-ordinates in the neighbourhood of a point if they are subjected to the transformation

$$u \ = v \ + \frac{1}{6}C \qquad v \ v \ v \ ;$$

where C's are constants, then show that u are geodesic co-ordinates in the neighbourhood of the origin O.

24. (a) If X is a vector field satisfying $\frac{X}{t} = 0$; show that a X X remains constant along the curve. Deduce that the magnitudes of the parallel vector fields are equal.
    (b) Prove that the unit tangent vector $= \frac{du}{ds}$ of a geodesic is a parallel vector field along the geodesic.

(c) Prove that the necessary and sufficient condition that a system of co-ordinates be geodesic with pole at P are that their second covariant derivatives with respect to the metric of the space all vanish at P.

(d) Prove that the geodesic curvature of a curve C on a surface S depends on the first fundamental form of S only.

25. Prove that the co-ordinate system u defined by

$$u = v \quad u_0 + \frac{1}{2} \quad {}_{P} (v \quad u_0)(v \quad u_0);$$

is a geodesic co-ordinate system with the pole at $P(u_0^1; u_0^2)$.

26. Prove that the catenoid,

$$ds^2 = a^2 \cosh^2 x^1 (dx^1)^2 + a^2 \cosh^2 x^2 (dx^2)^2$$

and the right helicoid

$$ds^2 = (dy^1)^2 + [(y^1)^2 + a^2](dy^2)^2$$

are locally isometric.

27. Prove that, if the system of co-ordinates is orthogonal, the non-vanishing Christofell symbols of the second kind are

$$\genfrac{}{}{0pt}{}{1}{1\ 1} = \frac{1}{2a_{11}}\frac{\partial a_{11}}{\partial u^1}; \quad \genfrac{}{}{0pt}{}{1}{1\ 2} = \frac{1}{2a_{11}}\frac{\partial a_{11}}{\partial u^2}; \quad \genfrac{}{}{0pt}{}{1}{2\ 2} = \frac{1}{2a_{11}}\frac{\partial a_{22}}{\partial u^1}$$

$$\genfrac{}{}{0pt}{}{2}{1\ 1} = \frac{1}{2a_{22}}\frac{\partial a_{11}}{\partial u^2}; \quad \genfrac{}{}{0pt}{}{2}{1\ 2} = \frac{1}{2a_{22}}\frac{\partial a_{22}}{\partial u^1}; \quad \genfrac{}{}{0pt}{}{2}{2\ 2} = \frac{1}{2a_{22}}\frac{\partial a_{22}}{\partial u^2}.$$

28. Prove that for a helicoids of non-zero pitch the sections by planes containing the axis are geodesics if and only if these sections are straight lines.

29. Prove that, on a general surface, a necessary and sufficient condition that the curve $v = c$ be a geodesic is $EE_2 + FE_1 \quad 2EF_1 = 0$ for all values of u, where $E = r_1^2; F = r_1 \cdot r_2; G = r_2^2$.

30. Prove that if a surface admits two orthogonal families of geodesics, it is isometric with the plane.

31. Show that, if the line element is of the form $ds^2 = (du^1)^2 + a_{22}(du^2)^2$, the Gaussian curvature is

$$= \frac{1}{\sqrt{a_{22}}}\frac{\partial^2}{(\partial u^1)^2}\sqrt{a_{22}}.$$

32. Prove that the Gaussian curvature is an invariant.

33. Find the Gaussian curvature of the surface given (in Monge form) by $z = f(x; y)$, where x and y are taken as parameters.

34. Show that the Gaussian curvature is $\frac{1}{}\frac{@^2}{@u^2}$ for a surface with the metric

$$ds^2 = (\ du)^2 + \quad {}^2(dv)^2$$

35. Show that for the sphere of radius c, with the equation of the form

$$x^1 = c \sin u^1 \cos u^2; x^2 = c \sin u^1 \sin u^2; \ x^3 = c \cos u^1;$$

where c is a constant, the total curvature is $\quad = \frac{1}{c^2}$.

36. Show that the surface given by

$$x^1 = f_1(u^1); \ x^2 = f_2(u^1); \ x^3 = u^2$$

is a developable, where $f_1; f_2$ are differentiable functions.

37. Determine whether the surface of a helicoid given by

$$x^1 = u^1 \cos u^2; \ x^2 = u^1 \sin u^2; x^3 = cu^1$$

is developable, where c is a constant and $u^1; u^2$ are curvilinear co-ordinates of the surface.

38. Show that the surface with the metric

    (a) $ds^2 = (\ du^1)^2 + [(\ du^1)^2 + \ c^2](du^2)^2$ is not developable.
    (b) $ds^2 = (\ u^2)^2(du^1)^2 + (\ u^1)^2(du^2)$ is developable.

39. Find the equations of the surface of revolution for which $ds^2 = du^2 + (\ a^2 \quad u^2)dv^2$.

40. Prove that a ruled surface $x(s; t) = y(s) + tz(s)$ is a developable surface if and only if $j[\underline{y;}\, z; \underline{z}]j = 0$, where a dot denotes the derivatives with respect to the arc length s of the curve $y(s)$ and [.,.,.] denotes the scalar triple product.

41. Find an analytic expression of the Gaussian curvature of a ruled surface and prove that a ruled surface is developable surface if and only if its Gaussian curvature vanishes.

42. Show that

    (i) $\quad_g = \quad " \qquad \frac{u}{ds} = " \qquad \frac{u}{ds}:$

(ii) $\,^2_g = a \quad \frac{}{s}\frac{}{s}$; and $\,_g = \varepsilon \quad \frac{}{s}$

(iii) $\frac{d^2u}{s^2} + \quad \frac{du}{s}\frac{du}{s} = \quad _g\varepsilon \quad a \quad \frac{du}{s}$:

43. Show that the geodesic curvature of the curve $u = c$ with the metric

$$ds^2 = \,^2(du)^2 + \,^2(dv)^2 \text{ is } \frac{1}{}\frac{\partial}{\partial u}:$$

44. When the parametric curves are orthogonal, prove that

$$^{(1)}_g = \frac{1}{2\sqrt{a_{22}}}\frac{\partial \log a_{11}}{\partial u^2} \text{ and } ^{(2)}_g = \frac{1}{2\sqrt{a_{11}}}\frac{\partial \log a_{22}}{\partial u^1}:$$

45. Deduce that

$$^{(1)}_g = \frac{1}{\sqrt{a}}\quad\frac{\partial}{\partial u^1}\quad\frac{a_{12}}{\sqrt{a_{11}}}\quad\frac{\partial\sqrt{a_{11}}}{\partial u^2}\quad ; \quad ^{(2)}_g = \frac{1}{\sqrt{a}}\quad\frac{\partial}{\partial u^2}\quad\frac{a_{12}}{\sqrt{a_{22}}} + \frac{\partial\sqrt{a_{22}}}{\partial u^1}\quad :$$

46. Prove that the geodesic curvatures for the co-ordinate curves are

$$^{(1)}_g = \frac{\sqrt{a}}{(a_{11})^{3/2}}\quad {}^{\;2}_{1\;1} \quad\text{and}\quad ^{(2)}_g = \frac{\sqrt{a}}{(a_{22})^{3/2}}\quad {}^{\;1}_{2\;2} \quad :$$

47. Prove that the necessary and sufficient condition for a curve on a surface to be a geodesic is that its geodesic curvature be zero.

48. Show that the formula for the Gaussian curvature can be written in the form

$$= \frac{1}{2\sqrt{a}}\quad\frac{\partial}{\partial u^1}\quad\frac{a_{12}}{a_{11}\sqrt{a}}\frac{\partial a_{11}}{\partial u^2}\quad\frac{1}{\sqrt{a}}\frac{\partial a_{22}}{\partial u^1}$$

$$+\frac{\partial}{\partial u^2}\quad\frac{2}{\sqrt{a}}\frac{\partial a_{12}}{\partial u^1}\quad\frac{1}{\sqrt{a}}\frac{\partial a_{11}}{\partial u^2}\quad\frac{a_{12}}{a_{11}\sqrt{a}}\frac{\partial a_{11}}{\partial u^1}\quad :$$

49. Prove that any circular helix C on a cylinder of revolution S is a geodesic on C.

50. Prove that if a geodesic on a surface of revolution cuts the meridians at a constant angle, the surface is a right cylinder.

51. Prove that the meridians of a ruled helicoid are geodesics.

52. Prove that the orthogonal trajectories of the helices on a helicoid are geodesics.

53. Show that if a geodesic on a surface of revolution cuts the medians at a constant angle, the surface is a right cylinder.

Chapter 7

Surfaces in Space

With the exception of occasional references to the surrounding space, our study of geometry of surfaces was carried out from the point of view of a two-dimensional being whose universe is determined by the surface parameters u^1 and u^2. The treatment of surfaces in space presented in this chapter was based entirely on the study of the first quadratic differential form. In this chapter, the geometric shape and properties of a surface have discussed in the neighbourhood of any of its points. Of curse, this problem is of fundamental importance.

7.1 The Tangent Vector

We are now going to investigate the properties of a surface in its relation to the surrounding space. Consequently, we are dealing with two distinct system of co-ordinates namely, the three orthogonal Cartesian co-ordinates for the surrounding space which we denote by $y^i; i = 1, 2, 3$ and the two curvilinear co-ordinates of the surface which we denote by $u^\alpha; \alpha = 1, 2$. Let us denote the equation of a surface S embedded in E^3 by

$$y^1 = y^1(u^1, u^2); \; y^2 = y^2(u^1, u^2); \; y^3 = y^3(u^1, u^2)$$

$$y^i = y^i(u^1, u^2); \; i = 1, 2, 3. \tag{7.1}$$

The line element of arc ds of a curve lying on S is determined by the formula,

$$ds^2 = a_{\alpha\beta}\, du^\alpha du^\beta; \text{ where } a_{\alpha\beta} = \frac{\partial y^i}{\partial u^\alpha}\frac{\partial y^i}{\partial u^\beta}. \tag{7.2}$$

The choice of Cartesian variables y^i in the space enveloping the surface is clearly not essential, and we could have equally well referred the points of E^3 to a curvilinear co-ordinate system X related to Y by the transformation

$$x^i = x^i(y^1, y^2, y^3).$$

Now, relative to the frame X , the line element in E^3 is given by

$$ds^2 = g_{mn}\,dx^m dx^n; \quad \text{where, } g_{mn} = \frac{\partial y^k}{\partial x^m}\frac{\partial y^k}{\partial x^n} \tag{7.3}$$

and the set of Eq. (7.1) for the surface S can be written as

$$S : x^i = x^i(u^1, u^2); \; i = 1, 2, 3. \tag{7.4}$$

If we take a small displacement du on the surface, the corresponding component of the displacement in space are given by

$$dx^i = \frac{\partial x^i}{\partial u}du \tag{7.5}$$

and hence expression (7.3) for the surface element of arc assumes the form

$$ds^2 = g_{ij}\,dx^i dx^j = g_{ij}\frac{\partial x^i}{\partial u}\frac{\partial x^j}{\partial u}\,du\;du \,: \tag{7.6}$$

A comparison of Eq. (7.6) with Eq. (7.2) leads to the conclusion that

$$a = g_{ij}\frac{\partial x^i}{\partial u}\frac{\partial x^j}{\partial u}; \; i, j = 1, 2, 3 \text{ and } ; \; = 1, 2. \tag{7.7}$$

Now, dx^i is a space vector and is surface invariant, i.e. its components are unaltered Gaussian co-ordinates alone one transformed. Similarly, du is a surface vector and is also a space invariant. Hence, if we regard [Eq. (7.5)] first from the point of view of a transformation of space co-ordinates and then from the point of view of a transformation of surface co-ordinates and then from the point of view of a transformation of surface co-ordinates, we see that $\frac{\partial x^i}{\partial u}$ is a contravariant space vector and also a covariant surface vector, so that, it may be represented by

$$dx^i = \frac{\partial x^i}{\partial u}du = x^i\,du \;; \quad \text{where, } x^i = \frac{\partial x^i}{\partial u}; \tag{7.8}$$

where the indices properly describe the tensor character of this set of quantities.

Let r be the position vector of an arbitrary point P on S. The point P is determined by a pair of Gaussian co-ordinates (u^1, u^2), or by a triplet of space co-ordinates (x^1, x^2, x^3). Accordingly, the vector r can be viewed as a function of the space variables x^i satisfying Eq. (7.4). Thus,

$$\frac{\partial}{\partial u} = \frac{\partial}{\partial x^i}\frac{\partial x^i}{\partial u}. \tag{7.9}$$

But $\frac{\partial \mathbf{r}}{\partial x^i}$ are the base vectors $\mathbf{b}_i$ at P, associated with the curvilinear co-ordinate system X, whereas $\frac{\partial \mathbf{r}}{\partial u^\alpha}$ are the base vectors $\mathbf{a}_\alpha$ at P relative to the Gaussian co-ordinate system U. Hence, Eq. (7.9) yields

$$\mathbf{a}_\alpha = \mathbf{b}_i \frac{\partial x^i}{\partial u^\alpha}. \tag{7.10}$$

It is clear from this representation that

$$\mathbf{a}_1 = \mathbf{b}_i \frac{\partial x^i}{\partial u^1} \text{ and } \mathbf{a}_2 = \mathbf{b}_i \frac{\partial x^i}{\partial u^2};$$

so that $\frac{\partial x^i}{\partial u^\alpha} \equiv x^i_\alpha$; $(\alpha = 1, 2)$, are the contravariant components of the surface base vectors $\mathbf{a}_\alpha$ referred to the base system $\mathbf{b}_i$. Thus, the set of quantities

$$x^i_1 : \left(\frac{\partial x^1}{\partial u^1}, \frac{\partial x^2}{\partial u^1}, \frac{\partial x^3}{\partial u^1} \right) \text{ and } x^i_2 : \left(\frac{\partial x^1}{\partial u^2}, \frac{\partial x^2}{\partial u^2}, \frac{\partial x^3}{\partial u^2} \right)$$

transform in a contravariant manner relative to the transformation of space co-ordinates x^i. Now the three surface vectors

$$x^1_\alpha : \left(\frac{\partial x^1}{\partial u^1}, \frac{\partial x^1}{\partial u^2} \right); x^2_\alpha : \left(\frac{\partial x^2}{\partial u^1}, \frac{\partial x^2}{\partial u^2} \right) \text{ and } x^3_\alpha : \left(\frac{\partial x^3}{\partial u^1}, \frac{\partial x^3}{\partial u^2} \right)$$

transform according to the covariant law with respect to the transformation of Gaussian surface co-ordinates u^α. Indeed, consider a transformation $u^\alpha = u^\alpha\left(\bar{u}^1, \bar{u}^2\right)$; then Eq. (7.4) of S go over into $x^i = x^i\left(\bar{u}^1, \bar{u}^2\right)$ and

$$\frac{\partial x^i}{\partial u^\alpha} = \frac{\partial x^i}{\partial \bar{u}^\beta} \frac{\partial \bar{u}^\beta}{\partial u^\alpha}. \tag{7.11}$$

But $\frac{\partial x^i}{\partial \bar{u}^\beta} = \bar{x}^i_\beta$; and Eq. (7.11) yields the covariant law

$$x^i_\alpha = \frac{\partial \bar{u}^\beta}{\partial u^\alpha} \bar{x}^i_\beta; \quad i = 1, 2, 3.$$

Let ds be an element of arc joining a pair of points $P(u^1, u^2)$ and $Q(u^1 + du^1, u^2 + du^2)$ on S. The direction of the line element ds is given by the direction parameters $\frac{du^\alpha}{ds} = \lambda^\alpha$. The same direction can be specified by an observer in the enveloping space by means of three parameters $\frac{dx^i}{ds} = \lambda^i$; and from the Eq. (7.5), we find that

$$\lambda^i = \frac{dx^i}{ds} = \frac{\partial x^i}{\partial u^\alpha} \frac{du^\alpha}{ds}; \text{ i.e. } \lambda^i = x^i_\alpha \lambda^\alpha. \tag{7.12}$$

This formula tells us that any surface vector A^α can be viewed as a space vector with components A^i determined by

$$A^i = x^i_\alpha A^\alpha. \tag{7.13}$$

We shall refer to a vector A^i determined by Eq. (7.13) as a *tangent vector to the surface* S.

7.2 The Normal Line

An entity that provides a characterisation of the shape of the surface as it appears from the enveloping surface is the normal line to the surface.

Let A and B be a pair of surface vectors drawn at some point P on the surface S, such that the rotation A ; B is positive. The unit normal vector to the surface S is orthogonal to both A and B and is so oriented that (A,B,) from a right-handed system (Figure 7.1), i.e.

$$"_{ijk} A^i B^j \;{}^k = 1 \qquad (7.14)$$

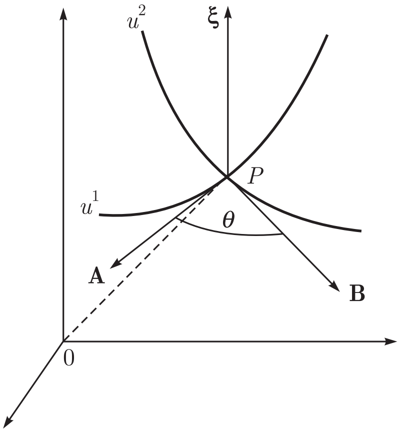


Figure 7.1: The normal lines to the surface.

where

$$= \frac{1}{jA \quad Bj}(A \quad B) = \frac{1}{AB\ \sin}(A \quad B)$$

where is the angle between A and B. We call the vector the unit normal vector to the surface S at P. Clearly, is a function of co-ordinates $u^1; u^2$, and as the point P $u^1; u^2$ is displaced to a new position Q $u^1 + du^1; u^2 + du^2$, the vector undergoes a change

$$d \;=\; \frac{@}{@u}du \;=\; \qquad du \;;\; \text{say;} \qquad (7.15)$$

whereas the position vector r is changed to the amount

$$dr = \frac{@}{@u}du \;=\; r \;\; du \;;\; \text{say.} \qquad (7.16)$$

The behaviour of the normal line as its foot displaced along the surface depends on the shape of the surface, and it occurred to Gauss to describe certain properties of surfaces with the aid of a quadratic form that depends in a fundamental way on the behaviour of the normal line. Let us form the scalar product

$$d\;\; dr = \frac{\partial}{\partial u}\;\;\frac{\partial}{\partial u} du\;\; du \;=\;\; r\;\; du\;\; du$$

$$=\;\; b\;\; du\;\; du\;\;;\;\; \text{say}; \tag{7.17}$$

if we define b as

$$b \;=\; \frac{1}{2}\;\;\frac{\partial}{\partial u}\;\;\frac{\partial}{\partial u} + \frac{\partial}{\partial u}\;\;\frac{\partial}{\partial u}$$

$$=\; \frac{1}{2}(\;\; r \;+\;\; r\;\;) \tag{7.18}$$

The left-hand side of Eq. (7.17), being the scalar product of two vectors, is an invariant. Thus, the second fundamental form is invariant with respect to any allowable co-ordinate transformation which preserves the sense of. Since the co-ordinate differentials du have a contravariant transformation behaviour and the second fundamental form is invariant, the coefficients b of this form are the components of a covariant tensor of second order with respect to co-ordinate transformations. From the quotient law, b is a covariant tensor of order (0,2) and from Eq. (7.18) it is symmetric with respect to and . The quadratic form

$$B\;\;\; b\;\; du\;\; du \tag{7.19}$$

introduced by Gauss, is called the second fundamental quadratic form of the surface. This differential form Eq. (7.19) plays an important part in the study of the geometry of the surface when they are viewed from the surrounding space.

Now, we shall write Eq. (7.14) in terms of the components x^i of the base vectors. The Eq. (7.13) tells us

$$A^i = x^i\, A\;\;;\;\; B^j = x^j\, B\;\;:$$

If be the angle between A^i and B^j, we can write

$$AB\,\sin\;\; = \varepsilon\;\;\; A\;\; B\;\;:$$

Let the contravariant components of the unit surface normal by ^{i} and the covariant components ${}_i$ is, then

$${}_i = \frac{\varepsilon_{ijk}\, x^j\, A\;\; x^k B}{\varepsilon\;\;\; A\;\; B}$$

or

$${}_i\,\varepsilon\;\;\;\; \varepsilon_{ijk}\, x^j\, x^k\;\;\; A\;\; B\;\; = 0:$$

This relation is valid for all surface vectors. Since, A and B are arbitrary, we have

$${}_i\epsilon \quad = \epsilon_{ijk}\, x^j\, x^k.$$

Multiplying this relation through by ϵ, and noting $\epsilon\ \epsilon = 2$, we get

$${}_i\epsilon\ \epsilon = \epsilon\ \epsilon_{ijk}\, x^j\, x^k$$

or

$${}_i\ 2 = \epsilon\ \epsilon_{ijk}\, x^j\, x^k$$

or

$${}_i = \frac{1}{2}\epsilon\ \epsilon_{ijk}\, x^j\, x^k.$$

It is clear from the structure of this formula that ${}_i$ is a space vector which does not depend on the choice of surface co-ordinates. This fact is also obvious from purely geometrical considerations.

EXAMPLE 7.2.1 Calculate the second fundamental form for the right helicoid given by $r = (u\cos v, u\sin v, cv)$.

Solution: Since $r = (u\cos v, u\sin v, cv)$, so

$$A = \frac{dr}{du} = (\cos v, \sin v, 0) \text{ and } B = \frac{dr}{dv} = (\quad u\sin v, u\cos v, c).$$

$$A \quad B = \begin{vmatrix} \hat{i} & \hat{j} & \hat{k} \\ \cos v & \sin v & 0 \\ u\sin v & u\cos v & c \end{vmatrix} = c\sin v\,\hat{i} \quad c\cos v\,\hat{j} + u\hat{k}.$$

Thus, the normal vector is given by

$$= \frac{1}{|A \quad B|}(A \quad B) = \frac{1}{\sqrt{c^2+u^2}}(c\sin v, \quad c\cos v, u).$$

The symmetric covariant tensor b are given by

$$b_{11} = \frac{1}{2}\left(\frac{\partial}{\partial u^1}\frac{\partial}{\partial u^1} + \frac{\partial}{\partial u^1}\frac{\partial}{\partial u^1}\right) = \frac{\partial}{\partial u^1}\frac{\partial}{\partial u^1} = \frac{\partial}{\partial u}\frac{\partial}{\partial u}$$

$$= \left(\frac{cu\sin v}{(c^2+u^2)^{\frac{3}{2}}}, \frac{cu\cos v}{(c^2+u^2)^{\frac{3}{2}}}, \frac{c^2}{(c^2+u^2)^{\frac{3}{2}}}\right) (\cos v, \sin v, 0) = 0$$

$$b_{22} = \frac{\partial}{\partial v}\cdot\frac{\partial}{\partial v} = \frac{1}{\sqrt{c^2+u^2}}(c\cos v; c\sin v; 0)\cdot(-u\sin v; u\cos u; c)$$

$$= \frac{1}{\sqrt{c^2+u^2}}(-uc\sin v\cos v + uc\sin v\cos v + 0) = 0$$

$$b_{12} = \frac{1}{2}\left(\frac{\partial}{\partial u^1}\cdot\frac{\partial}{\partial u^2} + \frac{\partial}{\partial u^1}\cdot\frac{\partial}{\partial u^2}\right) = \frac{1}{2}\left(\frac{\partial}{\partial u}\cdot\frac{\partial}{\partial v} + \frac{\partial}{\partial v}\cdot\frac{\partial}{\partial u}\right)$$

$$= \frac{1}{2}\left[\left(\frac{cu\sin v}{(u^2+c^2)^{\frac{3}{2}}}; \frac{cu\cos v}{(u^2+c^2)^{\frac{3}{2}}}; \frac{c^2}{(u^2+c^2)^{\frac{3}{2}}}\right)\cdot(-u\sin v; u\cos v; c)\right.$$

$$\left.+ \frac{1}{\sqrt{u^2+c^2}}(c\cos v; c\sin v; 0)\cdot(\cos v; \sin v; 0)\right]$$

$$= \frac{1}{2}\left[\frac{cu^2\sin^2 v + cu^2\cos^2 v + c^3}{(u^2+c^2)^{\frac{3}{2}}} + \frac{c\cos^2 v + c\sin^2 v}{\sqrt{u^2+c^2}}\right]$$

$$= \frac{1}{2}\left(\frac{c}{\sqrt{u^2+c^2}} + \frac{c}{\sqrt{u^2+c^2}}\right) = \frac{c}{(u^2+c^2)^{\frac{1}{2}}} = b_{21}.$$

Thus, the second fundamental quadratic form becomes

$$B \equiv b_{11}(du)^2 + 2b_{12}dudv + b_{22}(dv)^2 = 2b_{12}dudv \equiv \frac{2c}{(u^2+c^2)^{\frac{1}{2}}}dudv.$$

EXAMPLE 7.2.2 Calculate the second fundamental form for the paraboloid given by $r = (u; v; u^2 - v^2)$.

Solution: Since $r = (u; v; u^2 - v^2)$, so $A = (1; 0; 2u)$; $B = (0; 1; -2v)$ and

$$A \times B = -2u\hat{i} - 2v\hat{j} + \hat{k}.$$

Thus, the unit normal vector is given by

$$= \frac{1}{|A \times B|}(A \times B) = \frac{1}{\sqrt{4u^2+4v^2+1}}(-2u; -2v; 1).$$

The symmetric covariant tensors b are given by

$$b_{11} = \frac{\partial}{\partial u}\cdot\frac{\partial}{\partial u} = \frac{1}{(4u^2+4v^2+1)^{\frac{3}{2}}}\left(2(4v^2+1); -8uv; 4u\right)\cdot(1; 0; 2u)$$

$$= \frac{2(4u^2+1) + 8u^2}{(4u^2+4v^2+1)^{\frac{3}{2}}} = \frac{2}{\sqrt{4u^2+4v^2+1}}$$

$$b_{22} = \frac{\partial}{\partial v}\frac{\partial}{\partial v} = \frac{1}{(4u^2+4v^2+1)^{\frac{3}{2}}}\quad 8uv;\ \ 2(4u^2+1);4v\quad (0;1;\ \ 2v)$$

$$= \frac{2\ \ 4u^2+1\quad 8v^2}{(4u^2+4v^2+1)^{\frac{3}{2}}} = \quad \frac{2}{\sqrt{4u^2+4v^2+1}}$$

$$b_{12} = \frac{1}{2}\quad \frac{\partial}{\partial u}\frac{\partial}{\partial v} + \frac{\partial}{\partial v}\frac{\partial}{\partial u} = 0 = b_{21}:$$

Thus the second fundamental quadratic form becomes

$$B \quad b_{11}(du)^2 + b_{22}(dv)^2 + 2b_{12}dudv \quad \frac{2}{\sqrt{4u^2+4v^2+1}}\ (du)^2 \quad (dv)^2 \ :$$

EXAMPLE 7.2.3 Show a surface of revolution is regular and exhibit the unit surface normal.

Solution: The Gaussian form of a surface of revolution about z axis is

$$r(x^1;x^2) = \ f(x^1)\cos x^2; f(x^1)\sin x^2; g(x^1)\ ;\ f(x^1) > 0:$$

From this parametric representation, we get

$$A = \frac{\partial}{\partial x^1} = f'(x^1)\cos x^2; f'(x^1)\sin x^2; g'(x^1)\ ;$$

$$B = \frac{\partial}{\partial x^2} = \quad f(x^1)\sin x^2; f(x^1)\cos x^2; 0\ :$$

so

$$A \quad B = \quad fg'\cos x^2;\ \ fg'\sin x^2; ff'\ :$$

Therefore, the norm is $jA \quad Bj = f\sqrt{f'^2+g'^2}$: Now $f = f(x^1) \neq 0$; further, the generating curve is regular, which means that, with $t = x^1$, the tangent vector of the curve,

$$\frac{dx}{dt}; 0; \frac{dz}{dt} \quad = (f'; 0; g')$$

is non-null and $f'^2 + g'^2 \neq 0$: Therefore, $f\sqrt{f'^2+g'^2} \neq 0$ and the surface is regular. Thus, the unit surface normal vector is given by

$$= \frac{1}{jA \quad Bj}(A \quad B) = \frac{1}{f\sqrt{f'^2+g'^2}} \quad fg'\cos x^2;\ \ fg'\sin x^2; ff'$$

$$= \quad \frac{g'}{\sqrt{f'^2+g'^2}}\cos x^2;\ \ \frac{g'}{\sqrt{f'^2+g'^2}}\sin x^2; \frac{f'}{\sqrt{f'^2+g'^2}} \quad :$$

EXAMPLE 7.2.4 Prove that the tangent planes to a cone of revolution at the points of its generating straight lines coincide.

Solution: The parametric representation to a cone of revolution is

$$\vec{r} = (x^1, x^2, x^3) = (u^1 \cos u^2, u^1 \sin u^2, a u^1).$$

The first fundamental form of the surface, $a_{\alpha\beta}$ are given by

$$a_{11} = \left(\frac{\partial x^1}{\partial u^1}\right)^2 + \left(\frac{\partial x^2}{\partial u^1}\right)^2 + \left(\frac{\partial x^3}{\partial u^1}\right)^2 = 1 + a^2$$

$$a_{22} = \left(\frac{\partial x^1}{\partial u^2}\right)^2 + \left(\frac{\partial x^2}{\partial u^2}\right)^2 + \left(\frac{\partial x^3}{\partial u^2}\right)^2 = (u^1)^2$$

$$a_{12} = \frac{\partial x^1}{\partial u^1}\frac{\partial x^1}{\partial u^2} + \frac{\partial x^2}{\partial u^1}\frac{\partial x^2}{\partial u^2} + \frac{\partial x^3}{\partial u^1}\frac{\partial x^3}{\partial u^2} = 0.$$

Now $\vec{A}$ and $\vec{B}$ vectors are given by

$$\vec{A} = \frac{\partial \vec{r}}{\partial u^1} = (\cos u^2, \sin u^2, a)$$

$$\vec{B} = \frac{\partial \vec{r}}{\partial u^2} = (-u^1 \sin u^2, u^1 \cos u^2, 0).$$

Thus, the unit surface normal is given by

$$\vec{\xi} = \frac{1}{|\vec{A} \times \vec{B}|}(\vec{A} \times \vec{B}) = \left(-\frac{a \cos u^2}{\sqrt{1 + a^2}}, -\frac{a \sin u^2}{\sqrt{1 + a^2}}, \frac{1}{\sqrt{1 + a^2}}\right),$$

that is, the normal direction to the cone is independent of u^1. Since the curves $u^2 =$ constant are the generating straight lines of the cone, $\vec{\xi}$ is constant along any of those generators; hence the tangent planes to the cone at the points of any generating straight line coincide.

7.3 Tensor Derivative

In this section, we are introducing new tensors by differentiation of given vector fields. Consider a curve C lying on a given surface S. If A^i is a component of a space vector, defined along the curve C. If t is a parameter along C, the intrinsic derivative $\frac{\delta A^i}{\delta t}$ of A^i is given by

$$\frac{\delta A^i}{\delta t} = \frac{dA^i}{dt} + \left\{ {i \atop j\;k} \right\}_g A^j \frac{dx^k}{dt}. \tag{7.20}$$

The Christoffel symbols of second kind in Eq. (7.20) refer to the space co-ordinates x^i and are formed from the metric coefficients g_{ij}. This is indicated by the prefix g on the symbol. Again, if we consider a surface vector A, defined along the same curve C, we can form the intrinsic derivative with respect to the surface variables, namely,

$$\frac{A}{t} = \frac{dA}{dt} + {}_{a} \qquad A \frac{du}{dt}; \tag{7.21}$$

where the Christoffel symbols of second kind in Eq. (7.21) are formed from the metric coefficients a associated with the Gaussian surface co-ordinates u. The corresponding formulas for the intrinsic derivatives of the covariant vectors with components A_i and A are

$$\frac{A_i}{t} = \frac{dA_i}{dt} \quad {}_{g} \begin{matrix} k \\ i \ j \end{matrix} \quad A_k \frac{dx^i}{dt}$$

and

$$\frac{A}{t} = \frac{dA}{dt} \quad {}_{a} \qquad A \frac{du}{dt} \tag{7.22}$$

A geometric interpretation of these formulas is at hand where A^i and A are such that

$$\frac{A^i}{t} = 0 \text{ and } \frac{A}{t} = 0: \tag{7.23}$$

In the first case of Eq. (7.23) the vectors A^i form a parallel field with respect to C, considered as a space curve, where as in the later case of Eq. (7.23), the vectors A form a parallel field with respect to C regarded as a surface curve.

Consider a tensor field T^i, which is a contravariant vector with respect to a transformation of space co-ordinates x^i and a covariant vector relative to a transformation of the surface co-ordinates u. For example, a field of this type is a tensor x^i introduced in Eq. (7.8). If T^i is defined along a surface curve C, with t as parameter, then T^i is a function of t. We form an invariant

$$(t) = T^i A_i B \ ;$$

where a parallel vector field A_i along C, regarded as a space curve, and a parallel vector field B along C, viewed as a surface curve. The derivative of (t) with respect to the parameter t is given by

$$\frac{d\ (t)}{dt} = \frac{dT^i}{dt} A_i B + T^i \frac{dA_i}{dt} B + T^i A_i \frac{dB}{dt}; \tag{7.24}$$

which is obviously an invariant relative to both the space and surface co-ordinates. But since the fields $A_i(t)$ and B (t) are parallel,

$$\frac{dA_i}{dt} = {}_{g} \begin{matrix} k \\ i \ j \end{matrix} \quad A_k \frac{dx^i}{dt} \text{ and } \frac{dB}{dt} = {}_{a} \qquad B \frac{du}{dt}$$

therefore, Eq. (7.24) becomes

$$\frac{d}{dt} = \frac{dT^i}{dt} + \left\{ {i \atop j\;k} \right\} T^j \frac{dx^k}{dt} \quad a \qquad T^i \frac{du}{dt} \quad A_i B \ : \tag{7.25}$$

Since this is invariant for an arbitrary choice of parallel fields A_i and B , by quotient law, the expression in the bracket of Eq. (7.25) is a tensor of the same character as T^i with respect to the parameter t, and we write

$$\frac{T^i}{t} = \frac{dT^i}{dt} + \left\{ {i \atop j\;k} \right\} T^j \frac{dx^k}{dt} \quad a \qquad T^i \frac{du}{dt} : \tag{7.26}$$

If the field T^i is defined over the entire surface S, its components are functions of u s and we have a tensor field over the surface. Also, if C is any curve on the surface, we can argue that

$$\begin{aligned} \frac{T^i}{t} &= \frac{\partial T^i}{\partial u} + \left\{ {i \atop j\;k} \right\} T^j \frac{\partial x^k}{\partial u} \quad a \qquad T^i \ \frac{du}{dt} \\ &= \frac{\partial T^i}{\partial u} + \left\{ {i \atop j\;k} \right\} T^j x^k \quad a \qquad T^i \ \frac{du}{dt} \end{aligned}$$

is a tensor field. Since $\frac{du}{dt}$ is an arbitrary surface vector (for C is arbitrary) and since the right-hand side of this last equation is a tensor, we conclude that

$$T^i_{;} = \frac{\partial T^i}{\partial u} + \left\{ {i \atop j\;k} \right\} T^j x^k \quad a \qquad T^i \tag{7.27}$$

is a tensor which is singly contravariant in the space co-ordinates and doubly covariant in the surface co-ordinates. We shall call $T^i_{;}$, the tensor derivative of T^i with respect to u . Similarly, the tensor derivative of T^i with respect to u is given by

$$T^i_{;} = \frac{\partial T^i}{\partial u} + \left\{ {i \atop j\;k} \right\} T^j \ x^k \quad a \qquad T^i \quad a \qquad T^i \ : \tag{7.28}$$

If the surface co-ordinates at any point of the surface are geodesics and the space co-ordinates are orthogonal Cartesian, we see that at that point the tensor derivatives reduce to ordinary derivatives. This leads us to conclude that the operations of tensor differentiation of products and sums follow the usual rules and that the tensor derivatives of g_{ij} ; a ; " and their associated tensors vanish. Accordingly, they behave as constants in the tensor differentiation.

7.3.1 The Second Fundamental Form of a Surface

Before we introduce the new quadratic form, we must point out the relations, descriptions in the study of surfaces. Let us take the tensor derivative of the tensor x^i , representing the components of the surface base vectors , we find from Eq. (7.27) that

$$x^i_{;} = \frac{@^2 x^i}{@u \;\; @u} + {}_g \begin{matrix} i \\ j \;\; k \end{matrix} \; x^j x^k \quad {}_a \qquad x^i \tag{7.29}$$

from which it follows that $x^i_{;} = x^i_{;}$. Tensor differentiation of the relation a $= g_{mn} x^m x^n$ gives

$$g_{mn} x^m_{;} \; x^n + g_{mn} x^m x^n_{;} = 0: \tag{7.30}$$

Interchanging ; ; cyclically, we get

$$g_{mn} x^m_{;} \; x^n + g_{mn} x^m x^n_{;} = 0 \tag{7.31}$$

and

$$g_{mn} x^m_{;} \quad x^n + g_{mn} x^m x^n_{;} = 0: \tag{7.32}$$

Adding, Eqs. (7.31) and (7.32) and subtracting (7.30), we get

$$g_{mn} x^m_{;} \; x^n = 0; \;\; \text{as } x^m_{;} = x^m_{;} : \tag{7.33}$$

This orthogonality relation interpreted geometrically, states that $x^i_{;}$, from the point of view of the space co-ordinates is a space vector normal to the surface, and hence, it is codirectional with the normal vector ^{i}. Consequently, there must exist a set of functions such that

$$x^i_{;} = \quad {}^i; \tag{7.34}$$

where = b . The quantities b are the components of a symmetric surface tensor, and the differential quadratic form

$$B \quad b \;\; du \;\; du \tag{7.35}$$

is the desired second fundamental form. Equation (7.34) is known as Gauss's formula.

Deduction 7.3.1 Equivalence of the two definitions of the second fundamental quadratic form: Let us consider a surface S embedded in E^3 with the first fundamental form given by

$$ds^2 = a \quad du \;\; du$$

where (u^1, u^2) are the Gaussian co-ordinates for the surface S defined by

$$x^i = x^i(u^1, u^2), \quad i = 1, 2, 3,$$

x^i being the Cartesian co-ordinates of E^3. Let r be the position vector of any point P whose surface co-ordinates are (u^1, u^2) and space co-ordinates are (x^1, x^2, x^3). Now,

$$a = \frac{\partial}{\partial u}, \qquad = 1, 2,$$

are the surface base vectors and

$$b = \frac{\partial}{\partial x}, \qquad = 1, 2, 3,$$

are the space base vectors and they are usually related by

$$a = \frac{\partial}{\partial u} = \frac{\partial}{\partial x^i}\frac{\partial x^i}{\partial u} = x^i b_i. \qquad (7.36)$$

Let be the unit vector at P normal to the tangent plane, so, we get

$$= {}^i b_i \text{ and } = 1, \qquad a = 0. \qquad (7.37)$$

Since the vectors and a are orthogonal, so

$$\frac{\partial}{\partial u} = 0 \quad \text{and} \quad \frac{\partial}{\partial u} = 0.$$

Differentiating these two scalar products with respect to u and u, respectively, and then adding, we get

$$\frac{\partial}{\partial u}\ \frac{\partial}{\partial u} + \frac{\partial^2 r}{\partial u \partial u} + \frac{\partial}{\partial u}\ \frac{\partial}{\partial u} + \frac{\partial^2 r}{\partial u u} = 0$$

or

$$\frac{1}{2}\ \frac{\partial}{\partial u}\ \frac{\partial}{\partial u} + 2\ \frac{\partial^2 r}{\partial u \partial u} + \frac{\partial}{\partial u} . \frac{\partial}{\partial u} = 0$$

or

$$\frac{1}{2}\ \frac{\partial}{\partial u} . \frac{\partial}{\partial u} + \frac{\partial}{\partial u} . \frac{\partial}{\partial u} = .\frac{\partial^2 r}{\partial u \partial u}$$

or

$$b = .\frac{\partial^2 r}{\partial u \partial u} \quad \text{using Eq. (7.18).} \qquad (7.38)$$

Now, differentiating the relation $a = x^i b_i$ with respect to u; we get

$$\frac{\partial^2 r}{\partial u \partial u} = b_i \frac{\partial x^i}{\partial u} + \frac{\partial b_i}{\partial u} x^i = b_i \frac{\partial^2 x^i}{\partial u \partial u} + \frac{\partial b_i}{\partial x^j} x^i x^j$$

$$= b_h \quad \frac{\partial^2 x^h}{\partial u \partial u} + {}_g \genfrac{}{}{0pt}{}{h}{i\ j} \quad x^i x^j \quad ; \tag{7.39}$$

where in the last step, we made use of formula

$$\frac{\partial b_i}{\partial x^j} = {}_g \genfrac{}{}{0pt}{}{h}{i\ j} \quad b_h$$

for the derivatives of the base vector b_i: Using Eq. (7.29),

$$x^i_{;} = \frac{\partial^2 x^i}{\partial u \partial u} + {}_g \genfrac{}{}{0pt}{}{i}{j\ k} x^j x^k \quad {}_a \quad x^i$$

expression (7.39) reduces to

$$\frac{\partial^2 r}{\partial u \partial u} = x^h_{;} + {}_a \quad x^h \; b_h$$

$$= b \quad {}^h b_h + {}_a \quad x^h b_h; \quad \text{as } x^i_{;} = b \quad {}^i$$

$$= b \quad + {}_a \quad x^h a \;; \quad \text{using Eq. (7:37):} \tag{7.40}$$

Multiplying Eq. (7.39) scalarly by , we get

$$\frac{\partial^2 r}{\partial u \partial u} = b \quad + {}_a \quad x^h a$$

$$= b + 0 = b \;; \quad \text{as } a = 0 \tag{7.41}$$

This establishes the equivalence of the two definitions Eqs. [(7.38) and (7.41)] of the second fundamental quadratic form.

Deduction 7.3.2 The integrability conditions: In order to get insight into the significance of the tensor b, let us examine the Gauss's formula Eq. (7.34), as

$$x^i_{;} = b \quad {}^i;$$

where

$$x^i_{;} = \frac{\partial^2 x^i}{\partial u \partial u} + {}_g \genfrac{}{}{0pt}{}{i}{j\ k} x^j x^k \quad {}_a \quad x^i$$

$${}_i = \frac{1}{2}\varepsilon \quad \varepsilon_{ijk} x^j x^k \text{ and } x^i = \frac{\partial x^i}{\partial u}:$$

If we insert these expressions in Eq. (7.34), we obtain a set of second order partial differential equations, in which the dependent variables x^i are the functions of the surface co-ordinates u . The coefficients in the differential equations are functions of the metric coefficients g_{ij} of the manifold in which the surface S, defined by

$$x^i = x^i(u^1; u^2); \;\; i = 1; 2 \tag{7.42}$$

are immersed; they are also functions of

$$a \quad = g_{ij} \frac{@x^i}{@u} \frac{@x^j}{@u}$$

and b . If Eq. (7.42) is given, we can compute a and b , insert the approximate expressions in Eq. (7.34) and, of course, Eq. (7.34) will be satisfied identically.

Conversely, if the functions a and b are given, Eq. (7.34) will become the equation of conditions and in general they will have no solutions yielding Eq. (7.42) of the surface S. In order that the terms a and b are related to some surface, it is necessary that x^i satisfy the conditions of integrability

$$\frac{@^2 x^i}{@u @u} = \frac{@^2 x^i}{@u \; @u}; \tag{7.43}$$

whenever the function x_i are continuously differentiable of degree 2. Equation (7.43) is equivalent to

$$x^i_{;} \qquad x^i_{;} \quad = R \qquad x^i \;; \tag{7.44}$$

where R is the Riemann second kind curvature tensor, of type (1;3); formed with the coefficients a of the first fundamental quadratic form. Equation (7.44) involve third order partial derivatives of the co-ordinates x^i and we shall assume from now on that the functions entering in Eq. (7.42) are continuously thrice differentiable.

We shall see that the conditions of integrability Eq. (7.44) impose certain restrictions on the possible choice of functions b and a : These restrictive conditions are known as the equations of Gauss and Codazzi.

7.4 Structure Formulas for Surfaces

Two fundamental sets of relationships involve the parts of the moving triad $(A; B; \;)$ of a surface at any point P. Any vector bound at P can be represented as a linear combinations of those vectors. If the derive of those vectors exist, then the corresponding combinations are called the formulae of Frenet.

7.4.1 Equations of Weingarten

Weingarten's formula is an expression for the derivatives of the unit normal vector ^{i} to the surface S. Since ^{i}, the contravariant components of the normal vector is a unit vector, so,

$$g_{ij}\ ^i\ ^j = 1: \tag{7.45}$$

Here we have to show that the partial derivatives of this vector with respect to the co-ordinates u^1 and u^2 can be represented as a linear combination of vectors. Using the tensor derivative formula

$$^i_{;} = \frac{@^i}{@u} + {}_g \begin{matrix} i \\ j\ k \end{matrix}\ ^i x^k$$

we have from Eq. (7.45)

$$g_{ij}\ ^i_{;}\ ^j + g_{ij}\ ^i\ ^j_{;} = 0 \quad) \quad g_{ij}\ ^i\ ^j_{;} = 0: \tag{7.46}$$

Geometrically, Eq. (7.46) shows that $^j_{;}$; from the point of view of space co-ordinates, considered as a space vector, is orthogonal to the unit normal^i, and hence, it lies in the tangent plane to the surface. Accordingly, it can be expressed as a linear form in the base vectorsx^i , as

$$^i_{;} = c\ x^i\ ; \tag{7.47}$$

where c s are to be determined. Since ^{i} is normal to the surface, the tensor derivative of the orthogonality relation $g_{ij}\, x^i\ ^j = 0$ gives

$$g_{ij}\, x^i_{;}\ ^j + g_{ij}\, x^i\ ^j_{;} = 0$$

or

$$g_{ij}\, b\ ^i\ ^j + g_{ij}\, x^i\ ^j_{;} = 0;\ \text{as } x^i_{;} = b\ ^i$$

or

$$b + g_{ij}\, x^i\, c\ x^j = 0$$

or

$$b + a\ c = 0;\ \text{as } a = g_{ij}\, x^i\, x^j$$

or

$$a\ b + a\ a\ c = 0$$

or

$$c = a\ b\ ;\ \text{as } a\ a = : \tag{7.48}$$

Consequently, Eq. (7.47) reduces to

$$ {}^{i}_{;} = \quad a \quad b \quad x^{i} : \qquad (7.49) $$

These equations are known as Weingarten's formula, which can be used to derive the equations of Gauss and Codazzi. We have noticed that the formulae of Weingarten are the analogue of the formulae of Frenet. If we write

$$ C \quad = g_{ij} \ {}^{i}_{;} \ {}^{j}_{;} \ ; \qquad (7.50) $$

we see that C is symmetric tensor of order $(0;2)$ and we call the quadratic form

$$ C \quad C \quad du \ du \qquad (7.51) $$

the third fundamental form of the surface. Using Weingarten formula Eq. (7.49), we get

$$ \begin{aligned} C \quad &= g_{ij} \ {}^{i}_{;} \ {}^{j}_{;} = g_{ij} \quad a \quad b \quad x^{i} \quad a \quad b \quad x^{j} \\ &= a \quad a \quad b \quad a \quad b \quad = a \quad b \quad b \quad : \end{aligned} $$

This is a relation between three fundamental forms on a surface. This relation also shows that the third fundamental form is not actually a fundamental form, because this can be obtained from first and second fundamental forms.

Deduction 7.4.1 From the Weingarten formula Eq. (7.49), we get

$$ {}^{i}_{;} = \quad a \quad b \quad x^{i} = 0; \quad \text{if } b \quad = 0 : $$

Hence, ^{i} is a constant vector. Hence, the surface is a plane. Therefore, if $b \quad = 0$; then the normal vector to the surface is constant which means that the surface is a plane.

7.4.2 Equations of Gauss and Codazzi

The question arises whether, if functions $a \quad (u^1;u^2)$ and $b \quad (u^1;u^2)$ are given, there always exists a surface such that the given functions are the coefficients of the corresponding fundamental forms. In the case of functions of class 3 the answer to this problem is negative unless certain integrability conditions are satisfied which we will now derive. Let us consider the tensor derivative of Eq. (7.34), we get

$$ \begin{aligned} x^{i}_{;} \quad &= b_{;} \quad {}^{i} + b \quad {}^{i}_{;} \\ &= b_{;} \quad {}^{i} \quad b \quad a \quad b \quad x^{i} \ ; \ \text{using Eq. } (7{:}49) \end{aligned} $$

or

$$x^i_{;} \quad x^i_{;} = (b_{;} \quad b_{;})\ {}^i + b\ a\ b\ x^i \quad b\ a\ b\ x^i$$

$$= (b_{;} \quad b_{;})\ {}^i + a\ (b\ b \quad b\ b)x^i$$

or

$$(b_{;} \quad b_{;})\ {}^i \quad a\ (b\ b \quad b\ b)x^i \quad R \quad x^i\ ; \qquad (7.52)$$

if we write

$$x^i_{;} \quad x^i_{;} = R \quad x^i\ ;$$

where R is the Riemann curvature of the surface. Multiplying Eq. (7.52) by $_i$ and using the fact that $^i\ {}_i = 1$ and $x^i\ {}_i = 0$, we get

$$b_{;} \quad b_{;} = 0 : \qquad (7.53)$$

These equations are called the *Codazzi equations* of the surface, which will constitute all integrability conditions of the formulae of Weingarten. Again, multiplying Eq. (7.52) by $g_{ij}\ x^j$, we get

$$a\ R \quad = a\ b\ a\ b \quad a\ b\ a\ b$$

or

$$R \quad = b\ b \quad b\ b : \qquad (7.54)$$

These equations are called the *Gauss equations* of surface. Since $;$ assume values $1; 2$ and $b = b$; we see that there are two independent equations of Codazzi given by

$$b_{;} \quad b_{;} = 0; \quad \ne \qquad (7.55)$$

or

$$\frac{\partial b}{\partial u} \quad \frac{\partial b}{\partial u} \quad b \qquad + b \qquad = 0; \quad \ne$$

and only one independent equation of Gauss is

$$b = b_{11}b_{22} \quad b_{12}^2 = R_{1212}; \quad \text{where, } b = |b_{ij}| : \qquad (7.56)$$

This equation relates the coefficients b and a in the two fundamental quadratic forms. Thus, it follows from the theory of partial differential equation that if the tensors a and b are the fundamental tensors of the surface $S : x^i = x^i\ (u^1; u^2)$, Eqs. (7.53) and (7.56) are satisfied. Conversely, if the two sets of functions a and b satisfying Eqs. (7.53) and (7.56) are prescribed, and if $a\ du\ du$ is a positive definite form, then the surface S is determined (locally) to within a rigid body space.

Deduction 7.4.2 It is clear that, when = , we get identities from $b_{;}$ $b_{;}$ = 0 of the form 0 = 0: Again the equation with = p and = q is equivalent to the equation = q and = p. Hence, there are only two independent equations, as

$$b_{11;2} \quad b_{12;1} = 0 \text{ and } b_{21;2} \quad b_{22;1} = 0:$$

These two equations are equivalent to

$$b_{;} \quad b_{;} = 0; \quad 6= :$$

This shows that, $b_{;}$ $b_{;}$ = 0 is equivalent to $b_{;}$ $b_{;}$ = 0; 6= :

Deduction 7.4.3 From Codazzi equations, we get $b_{;}$ $b_{;}$ = 0; 6= : Let b = a ; then

$$b_{;} = {}_{;}\, a \quad \text{and } b_{;} = {}_{;}\, a$$

or

$${}_{;}\, a \qquad {}_{;}\, a = 0$$

or

$${}_{;}\, a \;\; a \qquad {}_{;}\, a \;\; a = 0$$

or

$$2 \; {}_{;} \qquad {}_{;} = 0 \;) \qquad {}_{;} = 0;$$

which implies that is a constant. Thus, if b = a ; where is a scalar, then is a constant.

7.4.3 Curvatures of a Surface

From Eq. (6.52), the total curvature of a surface is given by

$$= \frac{R_{1212}}{a}; \; a = a_{11}a_{22} \quad a_{12}^2 = ja_{ij}j: \tag{7.57}$$

Using the Gauss equation [Eq. (7.56)], the total curvature is given by

$$= \frac{b_{11}b_{22} \quad b_{12}^2}{a_{11}a_{22} \quad a_{12}^2} = \frac{b}{a}: \tag{7.58}$$

Thus, the Gaussian curvature is equal to the quotient of the determinants of the second and first fundamental quadratic forms. A surface S is said to be developable if = 0 identically at each point of the surface. A developable surface is a surface which can be developed into a plane. We now define another important invariant H , given by the formula

$$H \quad \frac{1}{2} a \quad b \; ; \tag{7.59}$$

which is called the mean curvature of the surface. The invariants ; H are connected with the ordinary curvatures of certain curves formed by taking normal sections of the surface (Section 8.2).

7.4.4 Minimal Surfaces

If at every point of a surface of class 2, the total curvature

$$H \quad \frac{1}{2} a \quad b \quad = 0; \tag{7.60}$$

then the surfaceS is called a minimal surface. Minimal surfaces derive their name from the fact that they are surfaces of minimum area satisfying given boundary conditions. They are illustrated by the shapes of thin soap films in equilibrium, with the air pressure the same on both sides. If this property of least area be taken as defining minimal surfaces, the use of the calculus of variations leads to the vanishing of the first curvature as an equivalent property. Later, we have to prove the following very important properties:

(i) Minimal surfaces cannot have elliptical points.
(ii) The lines of curvature on a minimal surfaces form an isometric system.
(iii) The asymptotic lines on a minimal surface form an orthogonal system.
(iv) Asymptotic lines on a minimal surface form on orthogonal system.

Theorem 7.4.1 (Theorema Egregium of Gauss): The Gaussian curvature is an intrinsic property of a surface, depending only on the first fundamental form and their derivatives but is independent of the second fundamental form.

Proof: The total curvature is given by

$$= \frac{b}{a} = \frac{b_{11}b_{22} \quad b_{12}^2}{a_{11}a_{22} \quad a_{12}^2}:$$

Thus, the total curvature, as obtained, depends upon the first fundamental form as well as the second fundamental form. But we have the equations of Gauss,

$$R \quad = b \quad b \quad b \quad b \quad ;$$

from which it follows that $R_{1212} = b_{11}b_{22} \quad b_{12}^2$: Therefore, $= \frac{R_{1212}}{a}$. But the Riemann curvature tensor depends only upon the first fundamental form a together with their derivatives. Hence, the theorem.

The practical question of whether inhabitants of a fog-enshrouded planet could, solely by measuring distances on the surface of the planet, determine its curvature, is answered in the affirmative by this theorem. Now,

(i) If two surfaces are locally isometric, then this theorem shows that, the Gaussian curvatures are identical.

(ii) Minding's theorem states that, if two surfaces are the same constant Gaussian curvature, then they are locally isometric.

(iii) In the case of constant Gaussian curvature, Beltrami's theorem tells us that there is a parameterisation for S for which the first fundamental form takes the form

Metric	Gaussian curvature
$ds^2 = a^2(dx^1)^2 + a^2 \sinh^2 x^1 (dx^2)^2$	$= \quad \frac{1}{a^2} < 0$
$ds^2 = (dx^1)^2 + (dx^2)^2$	$= 0$
$ds^2 = a^2(dx^1)^2 + a^2 \sin^2 x^1 (dx^2)^2$	$= \frac{1}{a^2} > 0$

(iv) From Eq. (7.54) we see that in case of surfaces of vanishing curvature (for example planes, cones, cylinders) all components of the curvature tensor are zero.

EXAMPLE 7.4.1 Show that

$$b \quad = g_{ij}\, x^{i}_{;} \quad {}^{j} = \frac{1}{2}" \quad "_{ijk}\, x^{i}_{;} \quad x^{j} x^{k}:$$

Solution: Equation (7.13) tells us $A^i = x^i \ A$; $B^j = x^j \ B$: If be the angle between the vectors A^i and B^j, we can write

$$AB \sin \quad = " \quad A \ B \ :$$

If is the unit surface normal, then

$${}_i = \frac{"_{ijk}\, x^j \ A \ \ x^k B}{" \ \ A \ B} \quad) \qquad {}_i" \qquad "_{ijk}\, x^j x^k \ \ A \ B \ = 0:$$

Since A and B are arbitrary, we have, ${}_i" \quad = "_{ijk}\, x^j x^k$ and therefore

$${}_i" \quad " \quad = " \quad "_{ijk}\, x^j x^k$$

or

$${}_i \ \ 2 = " \quad "_{ijk}\, x^j x^k \quad) \qquad {}_i = \frac{1}{2}" \quad "_{ijk}\, x^j x^k:$$

Using Eq. (7.34) as $x^i_{;} \quad = b \quad {}^i$, the Gauss's formula, we get

$$b \quad = x^i_{;} \quad {}_i = x^i_{;} \ g_{ij} \quad {}^j = g_{ij}\, x^i_{;} \quad {}^j:$$

Also, using the Eq. (7.34), we get

$$b \quad = g_{ij}\, x^i_{;} \quad {}_i = \frac{1}{2}"_{ijk}\, x^j x^k x^i_{;} \quad :$$

Combining these results, we get

$$b \quad = g_{ij}\, x^i_{;} \quad {}^j = \frac{1}{2}" \quad "_{ijk}\, x^i_{;} \quad x^j\, x^k:$$

EXAMPLE 7.4.2 Prove that C 2HB + A = 0; where the notations have their usual meaning.

Solution: The notations have the following expressions:

C : The third fundamental form of the surface c du du :
B : The second fundamental form of the surface b du du :
A : The first fundamental form of the surface a du du :
: The Gaussian curvature = $\frac{R_{1212}}{a}$:
H : The mean curvature of the surface = $\frac{1}{2}a \quad b$:
Let us take the Gauss's formula,

$$R \qquad = b \;\; b \qquad b \;\; b \quad \text{and}\; R \qquad = " \quad " \quad ;$$

we get

$$" \quad " \quad = b \;\; b \qquad b \;\; b \;\; :$$

Multiplying both sides by a , we get

$$" \quad " \quad a \quad = a \;\; b \;\; b \qquad a \;\; b \;\; b$$

or

$$a \qquad = a \;\; b \;\; b \qquad a \;\; b \;\; b \;\; ; \text{as}\, a \quad = \quad a \;\; " \quad "$$

or

$$a \qquad = 2Hb \qquad c \quad ; \;\text{as}\, c \quad = a \;\; b \;\; b$$

or

$$c \qquad 2Hb \quad + \; a \quad = 0$$

or

$$c \;\; du \;\; du \qquad 2Hb \;\; du \;\; du \; + \; a \quad du \;\; du \;\; = 0$$

or

$$C \quad 2HB + A = 0:$$

EXAMPLE 7.4.3 Show that

$$\text{(i)}\;\; a \quad c \quad = 4H^2 \quad 2: \qquad \text{(ii)}\;\; g_{ij} \;\; {}^i \; {}^j_{;} \quad = \quad c \;\; :$$

Solution: (i) Using the relation $a \quad = 2Hb \quad c$, we get

$$a \quad = 2Hb \quad c$$

or

$$= 2Hb \quad c \quad :$$

Also, using the relation $a \quad = 2Hb \quad c$, we get

$$c \; a \quad 2Hb \; a \; + a \; a \; = 0$$

or

$$a \; c \quad 2H \; 2H + \quad 2 = 0; \text{ as } a \; a \; = 2$$

or

$$c \; a \; = 4H^2 \quad 2 :$$

(ii) We know that, $g_{ij} \; {}^{i} \; {}^{j}_{;} = 0$: Taking the tensor derivative of both sides, we get

$$g_{ij} \; {}^{i}_{;} \; {}^{j}_{;} + g_{ij} \; {}^{i} \; {}^{j}_{;} \; = 0$$

or

$$g_{ij} \; {}^{i} \; {}^{j}_{;} \; = \; g_{ij} \; {}^{i}_{;} \; {}^{j}_{;} \; = \; c \; :$$

EXAMPLE 7.4.4 If b is the cofactor of b in $jb \; j$, divided by $jb \; j$, show that

$$x^i = \; a \; b \; {}^{i}_{;} :$$

Solution: From the definition,

$$b \; = \frac{\text{cofactor of } b \text{ in } jb \; j}{jb \; j}$$

with the property $b \; b \; = \;$: Hence,

$$a \; b \; x^{i}_{;} = \; a \; b \quad a \; b \; x^i \; = a \; a \; b \; b \; x^i$$

$$= a \; a \quad x^i = a \; a \; x^i = \quad x^i = x^i :$$

EXAMPLE 7.4.5 Find the Gaussian curvature at the point $(2; 0; 1)$ of the surface $(x^1)^2 \quad (x^2)^2 = 4x^3$; where $x^1; x^2; x^3$ are rectangular Cartesian co-ordinates.

Solution: Let the parametric representation of the surface is given by

$$x^1 = u^1 + u^2;\ x^2 = u^1 - u^2;\ x^3 = u^1u^2$$

i.e.

$$\mathbf{r} = (x^1; x^2; x^3) = (u^1 + u^2; u^1 - u^2; u^1u^2).$$

Therefore, at $(2; 0; 1)$, we have

$$u^1 = \frac{1}{2}(x^1 + x^2) = 1 \text{ and } u^2 = \frac{1}{2}(x^1 - x^2) = 1.$$

For the first fundamental form of the surface [Eq. (7.2)] the tensors $a_{\alpha\beta}$ are given by

$$a_{11} = \frac{\partial x^i}{\partial u^1}\frac{\partial x^i}{\partial u^1} = \left(\frac{\partial x^1}{\partial u^1}\right)^2 + \left(\frac{\partial x^2}{\partial u^1}\right)^2 + \left(\frac{\partial x^3}{\partial u^1}\right)^2$$
$$= 1^2 + 1^2 + (u^2)^2 = 2 + (u^2)^2.$$

$$a_{22} = \frac{\partial x^i}{\partial u^2}\frac{\partial x^i}{\partial u^2} = \left(\frac{\partial x^1}{\partial u^2}\right)^2 + \left(\frac{\partial x^2}{\partial u^2}\right)^2 + \left(\frac{\partial x^3}{\partial u^2}\right)^2$$
$$= 1^2 + (-1)^2 + (u^1)^2 = 2 + (u^1)^2.$$

$$a_{12} = \frac{\partial x^i}{\partial u^1}\frac{\partial x^i}{\partial u^2} = \frac{\partial x^1}{\partial u^1}\frac{\partial x^1}{\partial u^2} + \frac{\partial x^2}{\partial u^1}\frac{\partial x^2}{\partial u^2} + \frac{\partial x^3}{\partial u^1}\frac{\partial x^3}{\partial u^2}$$
$$= 1 \cdot 1 + 1 \cdot (-1) + u^2 \cdot u^1 = u^1u^2 = a_{21}.$$

Therefore,

$$a = \begin{vmatrix} 2 + (u^2)^2 & 0 \\ 0 & 2 + (u^2)^2 \end{vmatrix} = 2\{(u^1)^2 + (u^2)^2 + 2\}.$$

For the given parametric surface, $\mathbf{A} = (1; 1; u^2)$; $\mathbf{B} = (1; -1; u^1)$ and so

$$\mathbf{A} \times \mathbf{B} = (u^1 + u^2)\hat{\imath} + (u^2 - u^1)\hat{\jmath} - 2\hat{k}.$$

Therefore, the normal vector ξ is given by

$$\xi = \frac{1}{|\mathbf{A} \times \mathbf{B}|}(\mathbf{A} \times \mathbf{B}) = \frac{1}{\sqrt{2\{(u^1)^2 + (u^2)^2 + 2\}}}(u^1 + u^2; u^2 - u^1; -2).$$

Thus the covariant tensors $b_{\alpha\beta}$ for the second fundamental form are given by

$$b_{11} = \frac{1}{\sqrt{2}K^{\frac{3}{2}}}\ (u^2)^2 + 2 - u^1u^2;\ -\{(u^2)^2 + 2 + u^1u^2\};\ 2u^1 \cdot (1; 1; u^2);$$

[where $K = (u^1)^2 + (u^2)^2 + 1$];

$$= \frac{1}{\sqrt{2}K^{\frac{3}{2}}} \quad (u^2)^2 + 2 \quad u^1u^2 \quad (u^2)^2 \quad 2 \quad u^1u^2 + 2u^1u^2 \quad = 0.$$

$$b_{22} = \frac{1}{\sqrt{2}K^{\frac{3}{2}}} \quad (u^1)^2 + 2 \quad u^1u^2, \{(u^1)^2 + 2 + u^1u^2\}, 2u^2 \quad (1, \quad 1, u^1)$$

$$= \frac{1}{\sqrt{2}K^{\frac{3}{2}}} \quad (u^1)^2 + 2 \quad u^1u^2 \quad (u^1)^2 \quad 2 \quad u^1u^2 + 2u^1u^2 \quad = 0.$$

$$b_{12} = \frac{1}{2} \quad \frac{\partial}{\partial u^1} \quad \frac{\partial}{\partial u^2} + \frac{\partial}{\partial u^2} \quad \frac{\partial}{\partial u^1}$$

$$= \frac{2}{2\sqrt{2}} \left[\frac{(u^2)^2 + 1 + (u^1)^2}{\{(u^1)^2 + (u^2)^2 + 1\}^{\frac{3}{2}}} + \frac{(u^1)^2 + 1 + (u^2)^2}{\{(u^1)^2 + (u^2)^2 + 1\}^{\frac{3}{2}}} \right]$$

$$= \frac{2}{\sqrt{2\{(u^1)^2 + (u^2)^2 + 2\}}}.$$

Therefore,

$$b = \begin{vmatrix} 0 & \frac{2}{\sqrt{2\{(u^1)^2+(u^2)^2+2\}}} \\ \frac{2}{\sqrt{2\{(u^1)^2+(u^2)^2+2\}}} & 0 \end{vmatrix} = \frac{2}{(u^1)^2 + (u^2)^2 + 2}.$$

Thus, the Gaussian curvature is given by

$$= \frac{b}{a} = \frac{1}{[(u^1)^2 + (u^2)^2 + 2]^2} = \frac{1}{16}, \text{ at } (u^1, u^2) = (1, 1).$$

EXAMPLE 7.4.6 Find the Gaussian and mean curvature of the surface $x^1x^2 = x^3$.

Solution: Let the parametric representation of the surface (hyperbolic paraboloid) is given by, $x^1 = u^1, x^2 = u^2$ then, $x^3 = u^1u^2$. i.e.

$$r = (x^1, x^2, x^3) = (u^1, u^2, u^1u^2).$$

The symmetric covariant tensors a of the first fundamental form are given by

$$a_{11} = \left(\frac{\partial x^1}{\partial u^1}\right)^2 + \left(\frac{\partial x^2}{\partial u^1}\right)^2 + \left(\frac{\partial x^3}{\partial u^1}\right)^2 = 1 + (u^2)^2.$$

$$a_{22} = \left(\frac{\partial x^1}{\partial u^2}\right)^2 + \left(\frac{\partial x^2}{\partial u^2}\right)^2 + \left(\frac{\partial x^3}{\partial u^2}\right)^2 = 1 + (u^1)^2.$$

$$a_{12} = \frac{\partial x^1}{\partial u^1}\frac{\partial x^1}{\partial u^2} + \frac{\partial x^2}{\partial u^1}\frac{\partial x^2}{\partial u^2} + \frac{\partial x^3}{\partial u^1}\frac{\partial x^3}{\partial u^2} = u^1u^2 = a_{21}.$$

Therefore,

$$a = \begin{vmatrix} 1+(u^2)^2 & u^1u^2 \\ u^1u^2 & 1+(u^1)^2 \end{vmatrix} = 1+(u^1)^2+(u^2)^2.$$

The reciprocal tensors are given by

$$a^{11} = \frac{1+(u^1)^2}{1+(u^1)^2+(u^2)^2};\ a^{22} = \frac{1+(u^2)^2}{1+(u^1)^2+(u^2)^2};\ a^{12} = \frac{-u^1u^2}{1+(u^1)^2+(u^2)^2} = a^{21}.$$

Since $r = (x^1, x^2, x^3) = (u^1, u^2, u^1u^2)$, we have, $A = (1, 0, u^2)$; $B = (0, 1, u^1)$ and so

$$A \times B = -u^2\hat{i} - u^1\hat{j} + \hat{k}.$$

Therefore, the normal vector ν is given by

$$\nu = \frac{1}{|A \times B|}(A \times B) = \frac{1}{\sqrt{(u^1)^2+(u^2)^2+1}}(-u^2, -u^1, 1).$$

The symmetric covariant tensors $b_{\alpha\beta}$ are given by

$$b_{11} = -\frac{\partial \nu}{\partial u^1}\cdot\frac{\partial r}{\partial u^1} = -\frac{1}{\{(u^1)^2+(u^2)^2+1\}^{\frac{3}{2}}}\left(u^1u^2, -\{(u^2)^2+1\}, -u^1\right)\cdot(1, 0, u^2)$$

$$= -\frac{1}{\{(u^1)^2+(u^2)^2+1\}^{\frac{3}{2}}}\left(u^1u^2 - u^1u^2\right) = 0.$$

$$b_{22} = -\frac{\partial \nu}{\partial u^2}\cdot\frac{\partial r}{\partial u^2} = -\frac{1}{\{(u^1)^2+(u^2)^2+1\}^{\frac{3}{2}}}\left(-\{(u^1)^2+1\}, u^1u^2, -u^2\right)\cdot(0, 1, u^1)$$

$$= -\frac{1}{\{(u^1)^2+(u^2)^2+1\}^{\frac{3}{2}}}\left(u^1u^2 - u^1u^2\right) = 0.$$

$$b_{12} = -\frac{1}{2}\left(\frac{\partial \nu}{\partial u^1}\cdot\frac{\partial r}{\partial u^2} + \frac{\partial \nu}{\partial u^2}\cdot\frac{\partial r}{\partial u^1}\right)$$

$$= -\frac{1}{2}\left[\frac{-(u^2)^2-1-(u^1)^2}{\{(u^1)^2+(u^2)^2+1\}^{\frac{3}{2}}} - \frac{(u^1)^2+1+(u^2)^2}{\{(u^1)^2+(u^2)^2+1\}^{\frac{3}{2}}}\right]$$

$$= \frac{1}{\sqrt{(u^1)^2+(u^2)^2+1}} = b_{21}.$$

Therefore,

$$b = \begin{vmatrix} 0 & \frac{1}{\sqrt{(u^1)^2+(u^2)^2+1}} \\ \frac{1}{\sqrt{(u^1)^2+(u^2)^2+1}} & 0 \end{vmatrix} = -\frac{1}{(u^1)^2+(u^2)^2+1}.$$

The Gaussian curvature K is given by the formula,

$$K = \frac{b}{a} = -\frac{1}{\left[(u^1)^2 + (u^2)^2 + 1\right]^2} < 0.$$

Therefore, the mean curvature H is given by

$$H = \frac{1}{2}a^{\alpha\beta}b_{\alpha\beta} = \frac{1}{2}\left[a^{11}b_{11} + a^{22}b_{22} + 2a^{12}b_{12}\right]$$

$$= \frac{1}{2}\left[0 + 0 + \frac{u^1u^2}{1+(u^1)^2+(u^2)^2}\;\frac{1}{\sqrt{(u^1)^2+(u^2)^2+1}}\right]$$

$$= \frac{u^1u^2}{\left\{1+(u^1)^2+(u^2)^2\right\}^{3/2}}.$$

EXAMPLE 7.4.7 Find the mean curvature of the surface $\vec{r} = (u, v, u^2 - v^2)$.

Solution: For the first fundamental form of the surface [Eq. (7.2)], $a_{\alpha\beta}$ are given by

$$a_{11} = \left(\frac{\partial x^1}{\partial u}\right)^2 + \left(\frac{\partial x^2}{\partial u}\right)^2 + \left(\frac{\partial x^3}{\partial u}\right)^2 = 1 + 4u^2.$$

$$a_{22} = \left(\frac{\partial x^1}{\partial v}\right)^2 + \left(\frac{\partial x^2}{\partial v}\right)^2 + \left(\frac{\partial x^3}{\partial v}\right)^2 = 1 + 4v^2.$$

$$a_{12} = \frac{\partial x^1}{\partial u}\frac{\partial x^1}{\partial v} + \frac{\partial x^2}{\partial u}\frac{\partial x^2}{\partial v} + \frac{\partial x^3}{\partial u}\frac{\partial x^3}{\partial v} = -4uv = a_{21}.$$

Therefore,

$$a = (1+4u^2)(1+4v^2) - 16u^2v^2 = 1 + 4u^2 + 4v^2.$$

The reciprocal tensors are given by

$$a^{11} = \frac{1+4v^2}{1+4u^2+4v^2};\; a^{22} = \frac{1+4u^2}{1+4u^2+4v^2};\; a^{12} = \frac{4uv}{1+4u^2+4v^2} = a^{21}.$$

For the second fundamental form, the symmetric covariant tensors are given by

$$b_{11} = \frac{2}{\sqrt{1+4u^2+4v^2}};\; b_{22} = -\frac{2}{\sqrt{1+4u^2+4v^2}} \text{ and } b_{12} = 0 = b_{21}.$$

Therefore, the mean curvature H is given by

$$H = \frac{1}{2}a^{\alpha\beta}b_{\alpha\beta} = \frac{1}{2}\left[a^{11}b_{11} + a^{22}b_{22} + 2a^{12}b_{12}\right]$$

$$= \frac{1}{2}\left[\frac{2(1+4v^2)}{(1+4u^2+4v^2)^{3/2}} - \frac{2(1+4u^2)}{(1+4u^2+4v^2)^{3/2}} + 2\left(\frac{4uv}{1+4u^2+4v^2}\right)0\right]$$

$$= \frac{1+4v^2-1-4u^2}{(1+4u^2+4v^2)^{3/2}} = \frac{4(v^2-u^2)}{(1+4u^2+4v^2)^{3/2}}.$$

EXAMPLE 7.4.8 Show that the right helicoid given by

$$x^1 = u^1\cos u^2;\ x^2 = u^1\sin u^2;\ x^3 = cu^2$$

is a minimal surface.

Solution: For the first fundamental form of the surface [Eq. (7.2)], $a_{\alpha\beta}$ are given by

$$a_{11} = (\cos u^2)^2 + (\sin u^2)^2 + 0 = 1.$$

$$a_{22} = (-u^1\sin u^2)^2 + (u^1\cos u^2)^2 + (c)^2 = (u^1)^2 + c^2.$$

$$a_{12} = \frac{\partial x^1}{\partial u^1}\frac{\partial x^1}{\partial u^2} + \frac{\partial x^2}{\partial u^1}\frac{\partial x^2}{\partial u^2} + \frac{\partial x^3}{\partial u^1}\frac{\partial x^3}{\partial u^2}$$

$$= \cos u^2(-u^1\sin u^2) + \sin u^2(u^1\cos u^2) + 0 = 0 = a_{21}.$$

Therefore, $a = c^2 + (u^1)^2$. The reciprocal tensors are given by

$$a^{11} = \frac{c^2 + (u^1)^2}{c^2 + (u^1)^2} = 1;\ a^{22} = \frac{1}{c^2 + (u^1)^2};\ a^{12} = 0 = a^{21}.$$

Now, we calculate the tensors of second fundamental form. Since $\mathbf{r} = (x^1, x^2, x^3) = (u^1\cos u^2, u^1\sin u^2, cu^2)$; so,

$$\mathbf{A} = (\cos u^2, \sin u^2, 0) \text{ and } \mathbf{B} = (-u^1\sin u^2, u^1\cos u^2, c)$$

$$\mathbf{A}\times\mathbf{B} = \begin{vmatrix} \hat{i} & \hat{j} & \hat{k} \\ \cos u^2 & \sin u^2 & 0 \\ -u^1\sin u^2 & u^1\cos u^2 & c \end{vmatrix} = c\sin u^2\,\hat{i} - c\cos u^2\,\hat{j} + u^1\hat{k}$$

$$\mathbf{N} = \frac{1}{|\mathbf{A}\times\mathbf{B}|}(\mathbf{A}\times\mathbf{B}) = \frac{1}{\sqrt{c^2 + (u^1)^2}}(c\sin u^2, -c\cos u^2, u^1).$$

Thus, the covariant tensors $b_{\alpha\beta}$ for the second fundamental form are given by

$$b_{11} = 0;\ b_{22} = 0 \text{ and } b_{12} = -\frac{c}{\sqrt{c^2 + (u^1)^2}} = b_{21}.$$

Therefore, the mean curvature H is given by

$$H = \frac{1}{2}a^{\alpha\beta}b_{\alpha\beta} = \frac{1}{2}\left(a^{11}b_{11} + a^{22}b_{22} + 2a^{12}b_{12}\right)$$

$$= \frac{1}{2}\left[1\cdot 0 + \frac{1}{c^2 + (u^1)^2}\cdot 0 + 2\cdot 0\cdot\left(-\frac{c}{\sqrt{c^2 + (u^1)^2}}\right)\right] = 0.$$

Since the mean curvature $H = 0$, at every point of the given surface, so, it is a minimal surface.

EXAMPLE 7.4.9 Calculate the fundamental magnitudes for the conicoid

$$x^1 = u^1 \cos u^2;\ x^2 = u^1 \sin u^2;\ x^3 = f(u^2);$$

where $u^1; u^2$ are parameters. Find also Gaussian and mean curvature.

Solution: The parametric representation of the surface is given by

$$r = (x^1; x^2; x^3) = \left(u^1 \cos u^2;\ u^1 \sin u^2;\ f(u^2)\right);$$

The first fundamental magnitudes $a_{\alpha\beta}$ are given by

$$a_{11} = \left(\frac{\partial x^1}{\partial u^1}\right)^2 + \left(\frac{\partial x^2}{\partial u^1}\right)^2 + \left(\frac{\partial x^3}{\partial u^1}\right)^2 = (\cos u^2)^2 + (\sin u^2)^2 + 0^2 = 1;$$

$$a_{22} = \left(\frac{\partial x^1}{\partial u^2}\right)^2 + \left(\frac{\partial x^2}{\partial u^2}\right)^2 + \left(\frac{\partial x^3}{\partial u^2}\right)^2$$

$$= (-u^1 \sin u^2)^2 + (u^1 \cos u^2)^2 + f_1^2 = (u^1)^2 + f_1^2;$$

$$a_{12} = \frac{\partial x^1}{\partial u^1}\frac{\partial x^1}{\partial u^2} + \frac{\partial x^2}{\partial u^1}\frac{\partial x^2}{\partial u^2} + \frac{\partial x^3}{\partial u^1}\frac{\partial x^3}{\partial u^2} = 0 = a_{21};$$

where $f_1 = \frac{\partial f}{\partial u^2}$. Therefore,

$$a = \begin{vmatrix} a_{11} & a_{12} \\ a_{12} & a_{22} \end{vmatrix} = \begin{vmatrix} 1 & 0 \\ 0 & (u^1)^2 + f_1^2 \end{vmatrix} = (u^1)^2 + f_1^2.$$

The reciprocal tensors are given by

$$a^{11} = \frac{(u^1)^2 + f_1^2}{(u^1)^2 + f_1^2} = 1;\ a^{22} = \frac{1}{(u^1)^2 + f_1^2};\ a^{12} = \frac{0}{(u^1)^2 + f_1^2} = 0 = a^{21}.$$

Since $r = (x^1; x^2; x^3) = \left(u^1 \cos u^2;\ u^1 \sin u^2;\ f(u^2)\right)$, we have

$$A = (\cos u^2; \sin u^2; 0) \text{ and } B = (-u^1 \sin u^2; u^1 \cos u^2; f_1)$$

$$A \times B = \begin{vmatrix} \hat{\imath} & \hat{\jmath} & \hat{k} \\ \cos u^2 & \sin u^2 & 0 \\ -u^1 \sin u^2 & u^1 \cos u^2 & f_1 \end{vmatrix} = f_1 \sin u^2 \hat{\imath} + f_1 \cos u^2 \hat{\jmath} + u^1 \hat{k}$$

Therefore, the normal vector is given by

$$= \frac{1}{|A \times B|}(A \times B) = \frac{1}{\sqrt{(u^1)^2 + f_1^2}}\left(f_1 \sin u^2;\ -f_1 \cos u^2; u^1\right).$$

The symmetric covariant tensors b are given by

$$b_{11} = \frac{\partial}{\partial u^1}\frac{\partial}{\partial u^1} = (0\,;0;0)\cdot\frac{1}{\sqrt{(u^1)^2+f_1^2}}\left(f_1\sin u^2;\; f_1\cos u^2; u^1\right) = 0$$

$$b_{22} = \frac{\partial}{\partial u^2}\frac{\partial}{\partial u^2} = (\quad \sin u^2; \cos u^2; 0)\cdot\frac{1}{\sqrt{(u^1)^2+f_1^2}}\left(f_1\sin u^2;\; f_1\cos u^2; u^1\right)$$

$$= \frac{f_1}{\sqrt{(u^1)^2+f_1^2}}$$

$$b_{12} = \left(u^1\cos u^2;\; u^1\sin u^2; f_2\right)\cdot\frac{1}{\sqrt{(u^1)^2+f_1^2}}\left(f_1\sin u^2;\; f_1\cos u^2; u^1\right)$$

$$= \frac{u^1 f_2}{\sqrt{(u^1)^2+f_1^2}} = b_{21};$$

where $f_2 = \frac{\partial^2 f}{(\partial u^1)^2}$. Therefore,

$$b = \begin{vmatrix} b_{11} & b_{12} \\ b_{12} & b_{22} \end{vmatrix} = \begin{vmatrix} 0 & \frac{u^1 f_2}{\sqrt{(u^1)^2+f_1^2}} \\ \frac{u^1 f_2}{\sqrt{(u^1)^2+f_1^2}} & \frac{f_1}{\sqrt{(u^1)^2+f_1^2}} \end{vmatrix} = \frac{\left(u^1 f_2\right)^2}{(u^1)^2+f_1^2}.$$

The Gaussian curvature is given by the formula

$$= \frac{b}{a} = \frac{\left(u^1 f_2\right)^2}{\left((u^1)^2+f_1^2\right)^2} < 0.$$

Therefore, the mean curvature H is given by

$$H = \frac{1}{2}a\quad b = \frac{1}{2}\left(a^{11}b_{11} + a^{22}b_{22} + 2a^{12}b_{12}\right)$$

$$= \frac{1}{2}\left[0 + \frac{1}{(u^1)^2+f_1^2}\left(\frac{f_1}{\sqrt{(u^1)^2+f_1^2}}\right) + 0\right] = \frac{f_1}{2\{(u^1)^2+f_1^2\}^{3/2}}.$$

7.5 Exercises

1. Prove that the space vector perpendicular to ^{i} and tangent to the surface is

$$^i = x^i \quad ;$$

where ^{i} is the unit normal vector in the surface.

2. (i) Prove that for any curve on a surface $^{2} = {}^{2}_{g} + {}^{2}_{(n)}$:
   (ii) Prove that the covariant derivative $b_{;}$ can be written in the form

$$b_{;} = \frac{@b}{@u} \quad a \qquad b \quad a \qquad b \; :$$

3. Show that (i) $b = g_{ij} \, {}^{i}_{;} \, x^{j}$; (ii) $a \quad x^{r}_{;} = 2H \; {}^{r}$:
4. If the space co-ordinates are rectangular Cartesian, show that

$$b = \frac{1}{\sqrt{a}} "_{ijk} \frac{@^2 x^i}{@u@u} x^j_1 x^k_2 :$$

5. Show that a surface is a sphere if and only if its second fundamental form is a non-zero constant multiple of the first fundamental form.
6. Show that the second fundamental form for the
   (i) paraboloid $r = (u; v; u^2 \quad v^2)$ is given by

$$B \quad \frac{2}{\sqrt{4u^2 + 4v^2 + 1}}[(du)^2 \quad (dv)^2]:$$

   (ii) helicoid $r = (u \cos v; u \sin v; f(u) + cv)$ is given by

$$B \quad \frac{1}{\sqrt{u^2 + f_1^2 u^2 + c^2}}[uf_{11}(du)^2 \quad 2cdudv + f_1 u^2 (dv)^2]:$$

   (iii) the surface of revolution $r = (u \cos ; u \sin ; f(u))$ is given by

$$B \quad \frac{1}{\sqrt{1 + f_1^2}}[f_{11}(du)^2 + uf_1(d \;)^2]:$$

7. Determine the second fundamental form of a surface represented in the form $x_3 = f(x_1; x_2)$.
8. Prove by direct calculation that the coefficients of the second fundamental form are the components of a covariant tensor of second order with respect to co-ordinate transformations which preserve the sense of the unit normal vector.
9. Taking $x; y$ as parameters, calculate the fundamental magnitudes to the surface

$$2z = ax^2 + 2hxy + by^2$$

and show that the normal to the surface is given by

$$= \frac{1}{\sqrt{1 + (ax + hy)^2 + (hx + by)^2}}(\quad ax \quad hy; \quad hx \quad by; 1):$$

10. Show that the mean curvature for the

    (i) paraboloid $r = (u; v; u^2 \quad v^2)$ is given by

$$H = \frac{4(v^2 \quad u^2)}{[4u^2 + 4v^2 + 1]^{3=2}}:$$

    (ii) hyperbolic paraboloid $x^1 x^2 = x^3$ is given by

$$H = \quad \frac{x^3}{[(x^1)^2 + (x^2)^2 + 1]^{3=2}}:$$

    (iii) helicoid $r = (u \cos v; u \sin v; f(u) + cv)$ is given by

$$H = \frac{1}{2} \frac{(1 + f_1^2) u^2 f_1 + 2c^2 f_{11} + u f_{11} (u^2 + c^2)}{[u^2 + f_1^2 u^2 + c^2]^{3=2}}:$$

    (iv) right helicoid $r = (x^1; x^2; x^3) = \quad u^1 \cos u^2; u^1 \sin u^2; cu^2 \quad$ is zero.

11. Show that the Gaussian curvature for the

    (i) paraboloid $r = (u; v; u^2 \quad v^2)$ is given by

$$= \quad \frac{4}{[4u^2 + 4v^2 + 1]^2}:$$

    (ii) the surface of revolution $r = (u \cos \; ; u \quad \sin \; ; f \quad (u))$ is given by

$$= \frac{f_1 f_{11}}{u(1 + f_1^2)^2}:$$

    (iii) helicoid $r = (u \cos v; u \sin v; f(u) + cv)$ is given by

$$= \frac{u^3 f_1 f_{22} \quad c^2}{[u^2 + f_1^2 u^2 + c^2]^2}:$$

    (iv) right helicoid $r = (x^1; x^2; x^3) = \quad u^1 \cos u^2; u^1 \sin u^2; cu^2 \quad$ is given by

$$= \quad \frac{c^2}{(u^2 + c^2)^2}:$$

    (v) the anchor ring

$$r = (x^1; x^2; x^3) = \quad (b + a \cos u^1) \cos u^2; (b + a \cos u^1) \sin u^2; a \sin u^1$$

is given by $\quad = \dfrac{\cos u^1}{a(b + a \cos u^1)}:$

12. Calculate the fundamental magnitudes and unit normals for the
    (i) $x^1 = u^1 \cos u^2;\ x^2 = u^1 \sin u^2;\ x^3 = cu^2;$
    (ii) $x^1 = u^1 \cos u^2;\ x^2 = u^1 \sin u^2;\ x^3 = f(u^1),$
    (iii) $x^1 = u^1 \cos u^2;\ x^2 = u^1 \sin u^2;\ x^3 = f(u^1) + cu^2;$

    where $u^1; u^2$ are parameters. Find also Gaussian and mean curvature.
13. Determine the discriminant b of the second fundamental form of a sphere.
14. Prove that a surface for which at every point all coefficients of the second fundamental form vanish is a plane.
15. If two curves on a surface cut at right angles, show that the sum of their geodesic torsion is zero.
16. Prove that a surface, all of whose points are umbilics, is a sphere or a plane.
17. Prove that at each non-umbilical point of a surface, there exist two mutually orthogonal directions for which the normal curvature attains its extreme values.
18. Find the equation for the principal curvatures of the surface

$$x^1 = u^1;\ x^2 = u^2;\ x^3 = f(u^1; u^2);$$

    the x co-ordinates being rectangular Cartesian.
19. Show that the equation of the principal curvatures for
    (i) surface of revolution are $_{(1)} = \frac{f_{11}}{(1+f_1^2)^{3=2}}$ and $_{(2)} = \frac{f_1}{u(1+f_1^2)^{3=2}}$:
    (ii) surface $(x^1)^2 + (x^2)^2 + (x^3)^2 = 1$ are 1 and 1.
20. If two conjugate directions make angles $_1$ and $_2$ with a principal direction, show that

$$\tan\ _1 \tan\ _2 = \frac{1}{2}:$$

21. If a geodesic on a surface is a plane curve, show that it is also a line of curvature and conversely.
22. Prove that the lines of curvature on a surface are given by

$$"\quad a \quad a \quad du \ du = 0:$$

23. Show that the lines of curvature of the helicoid

$$x^1 = u^1 \cos u^2; x^2 = u^1 \sin u^2; x^3 = f(u^1) + cu^2$$

    are given by

$$c\ \ 1 + f_1^2 + u^1 f_1 f_{11}\ \ (du^1)^2 \quad c\ \ (u^1)^2 + c^2 + (u^1)^2 f_1^2\ \ (du^2)^2$$
$$+\ \ f(u^1)^2 + c^2 g u^1 f_{11} \quad (1 + f_1^2)(u^1)^2 f_1\ \ du^1 du^2 = 0:$$

24. Show that the lines of curvature for the surface catenoid, given by

$$x^1 = u^1 \cos u^2;\ x^2 = u^1 \sin u^2;\ x^3 = c \cosh^{1} \frac{u^1}{c};$$

where c is a constant, are the parametric curves.

25. If the co-ordinate curves are lines of curvature, prove that $a_{12} = 0 = b_{12}$ and conversely.

26. Calculate the Christoffel symbols of the second kind for the right helicoid, show that circular helices on the surface are geodesics.

27. Calculate $;H$ for two different parameterisation of the paraboloid $z = a(x^2 + y^2)$:

    (i) as the surface of revolution for which $f = x^1; g = a(x^1)^2$;
    (ii) as the surface $r = (y^1; y^2; a(y^1)^2 + a(y^2)^2)$:

    Interpret the results.

28. Find the values of the mean curvature H and Gaussian curvature , when parametric curves are asymptotic lines.

29. If be the angle between the asymptotic directions, find the value of $\tan\frac{}{2}$:

30. Prove that on a surface is given by

$$x^1 = a(u^1 + u^2); x^2 = b(u^1 \quad u^2);\ x^3 = u^1 u^2;$$

where a and b are constants, the parametric curves are asymptotic lines.

31. Show that the parametric curves are asymptotic lines of the surface

$$x^1 = u^1 \cos u^2; x^2 = u^1 \sin u^2; x^3 = a u^2:$$

Hints: For the surface we have to show that

$$b_{11} = 0; b_{22} = 0 \text{ and } b_{12} = \quad \frac{a}{\sqrt{a^2 + (u^1)^2}}:$$

32. Prove that for an asymptotic direction the normal curvature is zero.

33. Show that if every point of a surface S is parabolic, then S is developable.

Chapter 8

Curves on a Surface

In Chapter 7, we assumed the surface co-ordinates to be u and the space co-ordinates x^i, then the equation of a surface be given by

$$S : x^i = x^i(u^1; u^2): \qquad (8.1)$$

If the co-ordinates u are given as functions of a parameter then the point represented by these co-ordinates describes a curve on the surface as the parameter varies. We shall take the arc length s of the curve as the arc parameter and consequently, the equation of a smooth curve C lying on the surface S is given by

$$C: \quad u = u(s): \qquad (8.2)$$

We see from Eq. (8.1) that the space co-ordinates of any point of the curve are also functions of the arc parameter s and we obtain the space co-ordinates x^i in the form

$$S : x^i = x^i(s) = x^i \;\; u^1(s); u^2(s) \;\; ; \qquad (8.3)$$

which is the equation of C regarded as a space curve. The properties of C can then be studied with the aid of the Frenet{Serret formula, by analyzing the rates of change of the unit tangent vector , the unit principal normal and the unit binormal . Then its curvature and its torsion are connected with these vectors by the Frenet formulae [Eq. (5.17)] as

$$\begin{array}{l} \frac{\;^i}{s} = \;^i \\ \frac{\;^i}{s} = \;^i + \;^i \\ \frac{\;^i}{s} = \;^i \end{array} \qquad (8.4)$$

Considering the curve as a curve on the surface we shall denote its unit tangent vector by and its unit normal vector in the surface by :

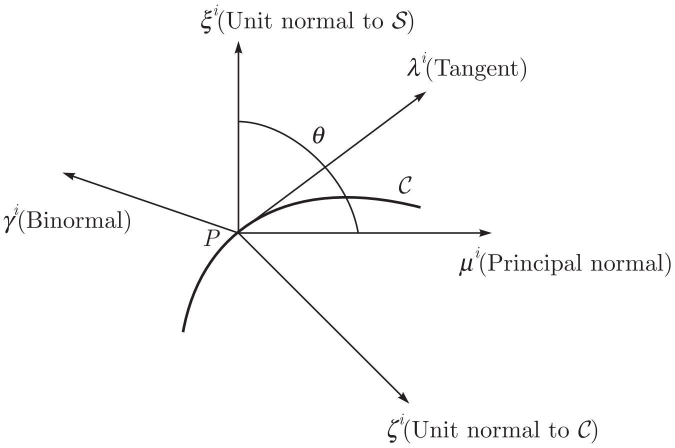
8.1 Curves Theory on a Surface

If we regard C as a surface curve, defined by Eq. (8.2), the components of the unit tangent vector are related to the space components ^{i} of the same vector by the formulas

$$^{i} = \frac{dx^i}{ds} = \frac{@x^i}{@u}\frac{du}{ds} \quad x^i \quad ; \text{ where } \quad = \frac{du}{ds}: \qquad (8.5)$$

If is the unit normal to C in the tangent plane to the surface (Figure 8.1) and $_g$ is the geodesic curvature of C, then from Eq. (6.61) we get

$$\frac{}{s} = {}_g \quad :$$



ξ^i(Unit normal to $\mathcal{S}$)
λ^i(Tangent)
θ
$\mathcal{C}$
γ^i(Binormal)
P
μ^i(Principal normal)
ζ^i(Unit normal to $\mathcal{C}$)

Figure 8.1: Tangent and normals on the surface.

If we differentiate Eq. (8.5) intrinsically with respect to s, we get

$$\frac{^i}{s} = x^i_{;} \quad \frac{du}{ds} + x^i \frac{}{s}$$

or

$$^i = x^i_{;} \quad + {}_g x^i \quad ;$$

where we use the Frenet formula $\frac{^i}{s} = \ {}^i$: Using the Gauss's formula $x^i_{;} \ = b \ \ ^i$ and the space components ^{i} of as $^i = x^i$; the Eq. (8.5) becomes

$$^i = b \qquad ^i + {}_g \ ^i; \qquad (8.6)$$

where ^{i} is the unit normal to the surface S. Formula (8.6) states that the principal normal to the curve C lies on the plane of the vectors and . Since ; and are orthogonal and = ; we have,

$$"_{ijk}\ ^{j}\ ^{k} = \ _{i}: \qquad (8.7)$$

Let be the angle between and : Since the tangent vector is orthogonal to the plane of and ; we have

$$= \sin\ ;\ \text{i.e.}\ "_{ijk}\ ^{j}\ ^{k} = \sin\ _{i}: \qquad (8.8)$$

On multiplying by , the foregoing Eq. (8.8) becomes

$$"_{ijk}\ ^{j}\ ^{k} = \sin\ _{i}$$

or

$$"_{ijk}\ b\ \ ^{j} + \ _{g}\ ^{j}\ \ ^{k} = \sin\ _{i};\ \text{using Eq. (8:6)}$$

or

$$_{g} = \sin\ ;\ \text{as}\ "_{ijk}\ ^{j}\ ^{k} = 0\ \text{and}\ "_{ijk}\ ^{j}\ ^{k} = \ _{i}: \qquad (8.9)$$

Also, as be the angle between the principal normal ^{i} and the surface normal ^{i}, then the angle between ^{i} and ^{i} is $\frac{}{2}$; therefore,

$$\cos = \ ^{i}\ ^{j}\ \text{and}\ \cos \frac{}{2} = \ ^{i}\ ^{j}:$$

Therefore, using Eq. (8.6), we get

$$^{i}\ ^{j} = b\ \ ^{i}\ ^{j} + \ _{g}\ ^{i}\ ^{j}$$

or

$$\cos = b\ \ ^{i}\ ^{j} + \ _{g}\ ^{i}\ ^{j} = b\ : \qquad (8.10)$$

From Eq. (8.10) we see that the quantity b is the same for all curves on the surface S which have the same tangent vector at P: In particular, it has the same value for the curve formed by the intersection of the normal plane containing and . But for every normal plane section the angle is either 0 or radians, so that for the normal plane section

$$\cos = \quad \text{or}$$

and consequently, cos is also the same for all such curves. Since b is an invariant, the value of cos for every curve C tangent to is equal to the curvature

$_{(n)}$ of the normal section in the direction . The curvature $_{(n)}$ is called the normal curvature of the surface S in the direction : Thus Eq. (8.10) can be written as

$$_{(n)} = \quad \cos \; = b \qquad : \tag{8.11}$$

Therefore, from Eq. (8.11), we state that, for all curves on a surface, which have the same tangent vector, the quantity cos has the same value, where is the angle between the surface normal and the principal normal, being the curvature of the curve. Accordingly, Eq. (8.6) can be written in the form

$$^{i} = \; _{(n)} \; ^{i} + \; _{g} \; ^{i} : \tag{8.12}$$

Equation (8.12) states that $_{(n)}$ and $_{g}$ are the components of the curvature ^{i} in the direction of the vectors ^{i} and ^{i}.

Result 8.1.1 The radius of curvature $= \frac{1}{}$ of any curve at a given point on the surface is equal to the product of the radius of curvature $_{(n)} = \frac{1}{_{(n)}}$ of the corresponding normal section at that point by cosine of the angle between the normal to the surface and the principal normal to the curve. This is known as Meusnier's theorem Mathematically, we have

$$= \; _{(n)} \cos : \tag{8.13}$$

If S is a sphere, every normal section is a great circle of the sphere, and C is any circle drawn on the sphere, then the result [Eq. (8.13)] becomes obvious from elementary geometric considerations.

If $ds^2 = a \quad du \; du$ and $= \frac{du}{ds}$; Eq. (8.11) can be written in the form

$$_{(n)} = b \qquad = b \; \frac{du}{ds}\frac{du}{ds}$$

$$= \frac{b \;\; du \; du}{ds^2} = \frac{b \;\; du \; du}{a \;\; du \; du} = \frac{B}{A} : \tag{8.14}$$

Result 8.1.2 If the surface is a plane, the normal curvature $_{(n)} = 0$ at all points of the plane, and if it is a sphere $_{(n)} = \frac{1}{R}$; where R is the radius of the sphere. Accordingly, we conclude from Eq. (8.14) that for the plane $b \quad = 0$: Also, for the sphere

$$b \quad du \; du \; = \frac{1}{R} a \quad du \; du \tag{8.15}$$

so that $a \quad = Rb$ at all points of the sphere and for all directions du . Therefore, for a sphere $b \quad = \frac{1}{R} a$, i.e. b and a are proportional.

Deduction 8.1.1 Since ^{i} is perpendicular to ^{i}, it lies in the plane containing ^{i} and ^{i}. Also, it is tangent to the surface and hence the angle between ^{i} and ^{i} is $\frac{}{2}$: If we multiply Eq. (8.6) by ^{i}, we get

$$\cos \frac{}{2} \quad = \ {}_g) \quad {}_g = \ \sin ; \tag{8.16}$$

which is the formula connecting the geodesic curvature of a surface curve with its curvature.

Deduction 8.1.2 From Eq. (8.14), we have

$$_{(n)} = \frac{b \ du \ du}{a \ du \ du} = \frac{B}{A}:$$

Squaring and adding Eqs. (8.11) and (8.16), we obtain

$$^2_{(n)} + \ ^2_g = (\ \cos \ )^2 + (\ \sin \ )^2 = \ ^2:$$

Also, from the Eq. (8.12), it follows that:

$$g_{ij} \quad ^i \ ^j = g_{ij} \, b \qquad ^i \ ^j + \ _g g_{ij} \ ^i \ ^j$$

or

$$\begin{aligned} &= b \qquad \cos \ + \ _g \cos \frac{}{2} \\ &= \ _{(n)} \cos \ + \ _g \sin \ : \end{aligned}$$

Deduction 8.1.3 On using relations (8.9) and (8.10), we get from Eq. (8.6)

$$^i = b \qquad ^i + \ _g \ ^i$$

or

$$^i = \ \cos \ ^i + \ \sin \ ^i$$

or

$$^i = \cos \ ^i + \sin \ ^i:$$

Deduction 8.1.4 If the surface is a plane, then any normal section at any point of the plane is a straight line and, therefore, its curvature is zero and hence $_{(n)} = 0:$ Therefore,

$$b \ du \ du \ = 0;$$

for all directions du , i.e. b $= 0:$ Thus, for a plane b $= 0:$

Deduction 8.1.5 The normal sections of a sphere are great circles, any other plane section is a small circle. At any point the circles of curvature are identical with the normal sections and therefore lie on the sphere.

EXAMPLE 8.1.1 Find the normal curvature of the right helicoid.

Solution: The parametric representation of the right helicoid is given by

$$x^1 = u^1 \cos u^2; \; x^2 = u^1 \sin u^2; \;\; x^3 = cu^2$$

i.e.

$$r = (x^1; x^2; x^3) = \; u^1 \cos u^2; \; u^1 \sin u^2; cu^2 \; :$$

The symmetric covariant second order tensors a for the first fundamental form of the surface are given by

$$a_{11} = 1; \quad a_{22} = (u^1)^2 + c^2 \text{ and } a_{12} = 0 = a_{21}:$$

$$) \, j \; a \; j = \begin{matrix} 1 & 0 \\ 0 & c^2 + (u^1)^2 \end{matrix} = c^2 + (u^1)^2 > 0:$$

The symmetric covariant tensors b for the second fundamental form are given by

$$b_{11} = 0; b_{22} = 0 \text{ and } b_{12} = \frac{c}{\sqrt{c^2 + (u^1)^2}}:$$

$$) \, j \; b \; j = \begin{matrix} 0 & \frac{c}{\sqrt{c^2+(u^1)^2}} \\ \frac{c}{\sqrt{c^2+(u^1)^2}} & 0 \end{matrix} = \frac{c^2}{c^2 + (u^1)^2}:$$

Therefore, the Gaussian curvature is given by

$$= \frac{jb \;\; j}{ja \;\; j} = \frac{c^2}{[c^2 + (u^1)^2]^2} < 0:$$

Thus, the given surface is a surface of negative curvature. Also, it is a minimal surface (as $H = 0$). Thus, the principal curvatures $_{(1)}$ and $_{(2)}$ are related as

$$_{(1)} + \; _{(2)} = 2H = 0 \text{ and } \; _{(1)} : \; _{(2)} = \; = \frac{c^2}{[c^2 + (u^1)^2]^2}:$$

Now, the normal curvature $_{(n)}$ of the given right helicoid is given by

$$_{(n)} = \frac{b \;\; du \;\; du}{a \;\; du \;\; du} = \frac{b_{11}(du^1)^2 + b_{22}(du^2)^2 + 2\,b_{12}du^1du^2}{a_{11}(du^1)^2 + a_{22}(du^2)^2 + 2\,a_{12}du^1du^2}$$

$$= \frac{\left[\,2c= \sqrt{c^2 + (\;u^1)^2}\,\right] du^1du^2}{(du^1)^2 + \{c^2 + (\;u^1)^2\}(du^2)^2}:$$

$$= \frac{1}{\sqrt{c^2 + (\;u^1)^2}}\,\frac{2cdu^1du^2}{[(du^1)^2 + \{c^2 + (\;u^1)^2\}(du^2)^2]}:$$

EXAMPLE 8.1.2 Prove that the normal curvatures in the directions of the co-ordinate curves are $\frac{b_{11}}{a_{11}}$ and $\frac{b_{22}}{a_{22}}$, respectively.

Solution: Let the co-ordinate curve or parametric curve be taken, then for u^1 curve; i.e. $du^2 = 0$, the normal curvature $_{(n1)}$ is given by

$$_{(n1)} = \frac{b \;\; du \;\; du}{a \;\; du \;\; du} = \frac{b_{11}(du^1)^2 + b_{22}(du^2)^2 + 2\,b_{12}du^1du^2}{a_{11}(du^1)^2 + a_{22}(du^2)^2 + 2\,a_{12}du^1du^2}$$

$$= \frac{b_{11}(du^1)^2}{a_{11}(du^1)^2} = \frac{b_{11}}{a_{11}}; \text{ as } du^1 \neq 0:$$

The normal curvature $_{(n2)}$ along the u^2 curve is given by

$$_{(n2)} = \frac{b \;\; du \;\; du}{a \;\; du \;\; du} = \frac{b_{11}(du^1)^2 + b_{22}(du^2)^2 + 2\,b_{12}du^1du^2}{a_{11}(du^1)^2 + a_{22}(du^2)^2 + 2\,a_{12}du^1du^2}$$

$$= \frac{b_{22}(du^2)^2}{a_{22}(du^2)^2} = \frac{b_{22}}{a_{22}}; \text{ as } du^2 \neq 0:$$

EXAMPLE 8.1.3 If a curve is a geodesic on the surface, prove that it is either a straight line or its principal normal is orthogonal to the surface at every point and conversely.

Solution: From the formula, $_g = \;\; \sin\;$; we get for a geodesic

$$_g = \;\; \sin \;\; = 0 \;) \;\; \text{either} \;\; = 0 \text{ or } \sin \;\; = 0:$$

Therefore, when $= 0$; the curve is a straight line. If $\sin \; = 0$; then $= 0$ or : If $= 0$ or , then the principal normal and the surface normal are colinear. Consequently, the principal normal is orthogonal to the surface at every point.

EXAMPLE 8.1.4 Given the paraboloid of revolution $S; x^3 = (\;x^1)^2 + (\;x^2)^2$: Determine the radius and centre of the circle of curvature of the normal section of S at a point $P : x^3 = x^3_0$ whose tangent at P is parallel to the x^1x^2-plane.

Solution: The intersection of the paraboloid S and the plane E : $x^3 = x_0^3$ is a circle (Figure 8.2) of radius $= \sqrt{x_0^3} = r_0$. This is not a normal section of S. Let be the angle between E and the normal to S, this can be obtained

$$\tan \frac{1}{2} \qquad = \tan \quad = 2r_0$$

or

$$\cos = \sin = \frac{\tan}{\sqrt{1+\tan^2}} = \frac{2r_0}{\sqrt{1+4r_0^2}}$$

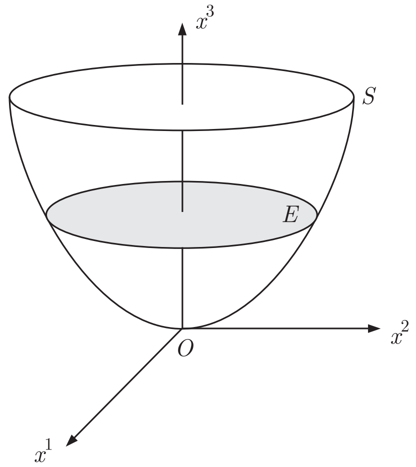


Figure 8.2: Paraboloid of revolution.

According to Meusnier's theorem we thus obtain

$${}_{(n)} = \frac{}{\cos} = \frac{1}{2}\sqrt{1+4r_0^2}$$

The centre of curvature of the normal section under consideration lies on the axis of revolution.

8.2 Principal Curvatures

The point of intersection of consecutive normals along a line of curvature at P is called a centre of curvature of the surface; and its distance from P, measured in the direction of the unit normal, is called a (principal) radius of curvature of the surface. The reciprocal of the principal radius of curvature is called a principal curvature.

Here, we will concern with the determination of the principal curvatures of a surface. In Section 8.1 we considered the normal curvature $_{(n)}$ at an arbitrary point

P of a surface as a function of the direction of the tangent to the normal sections at P as Eq. (8.14)

$$_{(n)} = \frac{b \quad du \ du}{ds^2} = \frac{b \quad du \ du}{a \quad du \ du} = \frac{B}{A}:$$

The normal curvature $_{(n)}$ at a point depends on the directions of $= \frac{du}{ds}$. We shall now nd out those directions $= \frac{du}{ds}$ (i.e. those values of $du^2 : du^1$) on the surface for which the normal curvature $_{(n)}$ has the extreme values. These directions are called the principal directions at the given point and the corresponding values for $_{(n)}$ are called principal normal curvatures of the surface at P. Let us denote $_{(n)}$ by $_{(p)}$ for the principal curvatures.

Since the vector is a unit vector, $_{(n)}$ has to be maximised subject to the constraint a $= 1$: The necessary condition for the extremum is

$$b \qquad + \#a \qquad = 0; \ \# = \text{ Lagrangian parameter}$$

or

$$b \qquad + \#a \qquad = 0$$

or

$$_{(p)} + \#1 = 0 \ ) \quad \# = \quad _{(p)}:$$

Thus, the equation, for the determination of directions yielding extreme values of $_{(n)}$ as $_{(p)}$; can be written as

$$b \qquad _{(p)}a \qquad = 0; \qquad = 1; 2: \tag{8.17}$$

The above set of homogeneous equations will possess non-trivial solutions for if and only if, the values of $_{(p)}$ are the roots of the determinant equation

$$b \qquad _{(p)}a \qquad = 0$$

or

$$\begin{matrix} b_{11} & _{(p)}a_{11} & b_{12} & _{(p)}a_{12} \\ b_{21} & _{(p)}a_{21} & b_{22} & _{(p)}a_{22} \end{matrix} = 0$$

or

$$b_{11}b_{22} \quad (a_{11}b_{22} + a_{22}b_{11}) \ _{(p)} + \ ^{2}_{(p)}a_{11}a_{22}$$
$$b_{12}b_{21} + (\ a_{12}b_{21} + \ a_{21}b_{12}) \ _{(p)} \qquad ^{2}_{(p)}a_{12}a_{21} = 0$$

or

$$(b_{11}b_{22} \quad b_{12}b_{21}) + {}^{2}_{(p)}(a_{11}a_{22} \quad a_{12}a_{21})$$
$$+ {}_{(p)}(a_{12}b_{21} + a_{21}b_{12} \quad a_{11}b_{22} \quad a_{22}b_{11}) = 0:$$

or

$$ {}^{2}_{(p)} \quad \frac{a_{11}b_{22} + b_{11}a_{22} \quad 2a_{12}b_{12}}{a} + \frac{b}{a} = 0; \quad b = jb \quad j; a = ja \quad j: \tag{8.18}$$

The roots of the quadratic Eq. (8.18) determine those directions for which the normal curvature ${}_{(n)}$ becomes extreme. Those directions are called the principal directions of normal curvature (or curvature directions) at the point P under consideration. The centres of curvature of the corresponding normal sections are called the centres of principal curvature of the surface S at P.

Also, since $a_{11} = aa^{22}; a_{12} = \quad aa^{21}; a_{21} = \quad aa^{12}$ and $a_{22} = aa^{11}$, so the above equation can be written in the form

$$a \, {}^{2}_{(p)} \quad (aa^{22}b_{22} + aa^{11}b_{11} + aa^{21}b_{21} + aa^{12}b_{12}) \, {}_{(p)} + b = 0$$

or

$$a \, {}^{2}_{(p)} \quad aa \quad b \quad {}_{(p)} + b = 0$$

or

$${}^{2}_{(p)} \quad a \quad b \quad {}_{(p)} + \frac{b}{a} = 0$$

or

$${}^{2}_{(p)} \quad 2H \, {}_{(p)} + \quad = 0; \tag{8.19}$$

where $H = \frac{1}{2}a \quad b$ is the mean curvature and $= \frac{b}{a}$ is the Gaussian curvature. We shall denote the two roots of ${}_{(p)}$ by ${}_{(1)}$ and ${}_{(2)}$ and call them the principal curvature of the surface and the directions corresponding to ${}_{(1)}$ and ${}_{(2)}$ are called principal directions of the surface. Note that, the principal directions on the surfaces are real.

Definition 8.2.1 Those portions of the surface on which the two principal curvatures ${}_{(1)}$ and ${}_{(2)}$ have the same sign are said to be synclasic. The surface of a sphere or of an ellipsoid as synclasic at all points. On the other hand if the principal curvatures have opposite signs on any part of the surface, this part is said to be anticlastic. The surface of a hyperbolic paraboloid is anticlastic at all points.

Result 8.2.1 The principal directions are real and orthogonal.

Proof: The reality of the principal directions is obvious geometrically. From Eq. (8.19) it is clear that, the principal curvatures ${}_{(1)}$ and ${}_{(2)}$ are related to the mean and Gaussian curvatures by the formulas

$${}_{(1)} + \;{}_{(2)} = 2H \text{ and } {}_{(1)}\;{}_{(2)} = \;: \qquad (8.20)$$

From Eq. (8.17), it follows that, the principal directions ${}_{(1)};\;{}_{(2)}$, say, corresponding to ${}_{(1)}$ and ${}_{(2)}$, respectively, are determined by

$$\left.\begin{array}{l} b \quad {}_{(1)}a \quad {}_{(1)} = 0 \\ b \quad {}_{(2)}a \quad {}_{(2)} = 0 \end{array}\right) \qquad (8.21)$$

Multiplying the first part of Eq. (8.21) by ${}_{(2)}$ and second part of Eq. (8.21) by ${}_{(2)}$ and subtracting, we get

$${}_{(2)} \quad {}_{(1)} \; a \quad {}_{(1)}\;{}_{(2)} = 0: \qquad (8.22)$$

A point at which ${}_{(1)} = \;{}_{(2)}$ is called an umbilic point or naval point. At an umbilic point, Eq. (8.19) has coincident roots, i.e. $H^2 = \;$; so that, it can be written in the form

$$\Big[\; a \quad b \;\Big]^2 = 4\frac{b}{a}$$

or

$$a^{11}b_{11} + a^{22}b_{22} + a^{21}b_{21} + a^{12}b_{12} \;{}^2 = 4\frac{b}{a}$$

or

$$4a(a_{11}b_{12} \quad a_{12}b_{11})^2 + [a_{11}(a_{11}b_{22} \quad a_{22}b_{11}) \quad 2a_{12}(a_{11}b_{12} \quad a_{12}b_{11})]^2 = 0:$$

Since $a_{ij}\,dx^i dx^j$ is positive definite, a is positive, and thus, we have

$$a_{11}b_{12} \quad a_{12}b_{11} = a_{11}b_{22} \quad a_{22}b_{11} = 0$$

$$) \quad \frac{b_{11}}{a_{11}} = \frac{b_{12}}{a_{12}} = \frac{b_{22}}{a_{22}}: \qquad (8.23)$$

Thus, at an umbilic we have the above condition Eq. (8.23). From Eq. (8.14), since

$${}_{(n)} = \frac{b \quad du \; du}{a \quad du \; du};$$

so, ${}_{(n)}$ is independent of the direction $\frac{du}{ds}$; i.e. at an umbilic, the normal curvature is the same in every directions. At all other points where ${}_{(1)} \neq \;{}_{(2)}$, we have

$$a \quad {}_{(1)}\;{}_{(2)} = 0: \qquad (8.24)$$

Therefore, at each non-umbilical point of a surface there exist two mutually orthogonal directions for which the normal curvature attains its extreme values.

If the principal curvatures at any point of a surface are equal in magnitude and opposite in sign and the indication is a rectangular hyperbola then it is a minimal surface.

EXAMPLE 8.2.1 Find the principal curvature of the surface defined by

$$x^1 = u^1, x^2 = u^2; \quad x^3 = f(u^1, u^2).$$

Solution: The parametric representation of the given curve is given by

$$x^1 = u^1;\ x^2 = u^2;\ x^3 = f(u^1, u^2)$$

i.e.

$$r = (x^1, x^2, x^3) = \left(u^1, u^2, f(u^1, u^2)\right).$$

The symmetric covariant second order tensors $a_{\alpha\beta}$ for the first fundamental form of the surface are given by

$$a_{11} = \left(\frac{\partial x^i}{\partial u^1}\right)^2 = 1^2 + 0^2 + \left(\frac{\partial f}{\partial u^1}\right)^2 = 1 + f_1^2.$$

$$a_{22} = \left(\frac{\partial x^i}{\partial u^2}\right)^2 = 0^2 + 1^2 + \left(\frac{\partial f}{\partial u^2}\right)^2 = 1 + f_2^2.$$

$$a_{12} = \frac{\partial x^i}{\partial u^1}\frac{\partial x^i}{\partial u^2} = 1.0 + 0.1 + \frac{\partial f}{\partial u^1}\frac{\partial f}{\partial u^2} = f_1 f_2 = a_{21}$$

where $f_1 = \frac{\partial f}{\partial u^1}$ and $f_2 = \frac{\partial f}{\partial u^2}$. Therefore,

$$a = |a_{\alpha\beta}| = \begin{vmatrix} 1 + f_1^2 & f_1 f_2 \\ f_1 f_2 & 1 + f_2^2 \end{vmatrix} = 1 + f_1^2 + f_2^2.$$

The reciprocal tensors are given by

$$a^{11} = \frac{1 + f_2^2}{1 + f_1^2 + f_2^2};\quad a^{22} = \frac{1 + f_1^2}{1 + f_1^2 + f_2^2};\quad a^{12} = \frac{-f_1 f_2}{1 + f_1^2 + f_2^2} = a^{21}.$$

Now, we calculate the tensors of second fundamental form. Since

$$r = (x^1, x^2, x^3) = \left(u^1, u^2, f(u^1, u^2)\right);$$

so

$$A=(1,0,f_1) \text{ and } B=(0,1,f_2);\quad A\times B=(-f_1,-f_2,1)$$

$$\xi=\frac{1}{|A\times B|}(A\times B)=\frac{1}{\sqrt{f_1^2+f_2^2+1}}(-f_1,-f_2,1).$$

Thus, the covariant tensors $b_{\alpha\beta}$ for the second fundamental form are given by

$$\begin{aligned}
b_{11}&=-\frac{\partial\xi}{\partial u^1}\cdot\frac{\partial X}{\partial u^1}=-(f_1^2+f_2^2+1)^{-1/2}[(-f_{11},-f_{12},0)\cdot(1,0,f_1)\\
&\quad-(f_1^2+f_2^2+1)(f_1f_{11}+f_2f_{12})(-f_1,-f_2,1)\cdot(1,0,f_1)]\\
&=\frac{f_{11}}{\sqrt{f_1^2+f_2^2+1}}.\\
b_{22}&=-\frac{\partial\xi}{\partial u^2}\cdot\frac{\partial X}{\partial u^2}=-(f_1^2+f_2^2+1)^{-1/2}[(-f_{21},-f_{22},0)\cdot(0,1,f_2)\\
&\quad-(f_1^2+f_2^2+1)(f_1f_{21}+f_2f_{22})(f_1,f_2,-1)\cdot(0,1,f_2)]\\
&=\frac{f_{22}}{\sqrt{f_1^2+f_2^2+1}}.
\end{aligned}$$

$$\begin{aligned}
b_{12}&=\frac{1}{2}\left(-\frac{\partial\xi}{\partial u^1}\cdot\frac{\partial X}{\partial u^2}+-\frac{\partial\xi}{\partial u^2}\cdot\frac{\partial X}{\partial u^1}\right)=-\frac{1}{2}(f_1^2+f_2^2+1)^{-1/2}[\{(-f_{11},-f_{12},0)\cdot(0,1,f_2)\\
&\quad+(f_1^2+f_2^2+1)(f_1f_{11}+f_2f_{12})(-f_1,-f_2,1)\cdot(0,1,f_2)\}\\
&\quad+\{(-f_{21},-f_{22},0)\cdot(1,0,f_1)+(f_1^2+f_2^2+1)(f_1f_{21}+f_2f_{22})(f_1,f_2,-1)\cdot(1,0,f_1)\}]\\
&=\frac{f_{12}}{\sqrt{f_1^2+f_2^2+1}}=b_{21}.
\end{aligned}$$

The symmetric covariant tensors $b_{\alpha\beta}$ for the second fundamental form are given by

$$b_{11}=\frac{f_{11}}{\sqrt{f_1^2+f_2^2+1}},\ b_{22}=\frac{f_{22}}{\sqrt{f_1^2+f_2^2+1}} \text{ and } b_{12}=\frac{f_{12}}{\sqrt{f_1^2+f_2^2+1}}=b_{21}.$$

$$\Rightarrow\ b=|b_{\alpha\beta}|=\begin{vmatrix}\frac{f_{11}}{P} & \frac{f_{12}}{P}\\ \frac{f_{12}}{P} & \frac{f_{22}}{P}\end{vmatrix}=\frac{f_{11}f_{22}-f_{12}^2}{1+f_1^2+f_2^2};\quad P=\sqrt{f_1^2+f_2^2+1};$$

where $f_i=\frac{\partial f}{\partial u^i}$ and $f_{ij}=\frac{\partial^2 f}{\partial u^i\partial u^j}$. The equation giving the principal curvatures is

$$\kappa^2-a^{\alpha\beta}b_{\alpha\beta}\kappa+\frac{b}{a}=0$$

or

$$\kappa^2 - \kappa\left[(f_{11}+f_{22}) - \frac{f_1^2 f_{11} + f_2^2 f_{22} + 2f_1 f_2 f_{12}}{1+f_1^2+f_2^2}\right] + f_{11}f_{22} - f_{12}^2 = 0.$$

This is a quadratic equation in κ which gives the two values of κ. At an umbilic, we have

$$\frac{b_{11}}{a_{11}} = \frac{b_{12}}{a_{12}} = \frac{b_{22}}{a_{22}} \Rightarrow \frac{f_{11}}{1+f_1^2} = \frac{f_{12}}{f_1 f_2} = \frac{f_{22}}{1+f_2^2}.$$

EXAMPLE 8.2.2 Find the principal curvature of the surface defined by

$$x^1 = u^1 \cos u^2;\ x^2 = u^1 \sin u^2;\ x^3 = f(u^1).$$

Find the condition that it is a minimal surface.

Solution: The parametric representation of the surface of revolution is given by

$$x^1 = u^1 \cos u^2; x^2 = u^1 \sin u^2;\ x^3 = f(u^1)$$

i.e.

$$\mathbf{r} = (x^1; x^2; x^3) = \left(u^1 \cos u^2; u^1 \sin u^2; f(u^1)\right).$$

The first fundamental magnitudes $a_{\alpha\beta}$ of the surface are given by

$$a_{11} = 1 + f_1^2;\ a_{22} = (u^1)^2 \text{ and } a_{12} = 0 = a_{21}.$$

$$\Rightarrow a = |a_{\alpha\beta}| = \begin{vmatrix} 1+f_1^2 & 0 \\ 0 & (u^1)^2 \end{vmatrix} = (u^1)^2(1+f_1^2);$$

where $f_1 = \frac{\partial f}{\partial u^1}$. The reciprocal tensors are given by

$$a^{11} = \frac{1}{1+f_1^2};\ a^{22} = \frac{1}{(u^1)^2};\ a^{12} = 0 = a^{21}.$$

The symmetric covariant tensors $b_{\alpha\beta}$ for the second fundamental form are given by

$$b_{11} = \frac{f_{11}}{\sqrt{1+f_1^2}}; b_{22} = \frac{u^1 f_1}{\sqrt{1+f_1^2}} \text{ and } b_{12} = 0 = b_{21}.$$

$$\Rightarrow |b_{\alpha\beta}| = \begin{vmatrix} \frac{f_{11}}{\sqrt{1+f_1^2}} & 0 \\ 0 & \frac{u^1 f_1}{\sqrt{1+f_1^2}} \end{vmatrix} = \frac{u^1 f_1 f_{11}}{1+f_1^2};$$

where $f_1 = \frac{\partial f}{\partial u^1}$ and $f_{11} = \frac{\partial^2 f}{\partial u^1 \partial u^1}$. The equation giving the principal curvatures is

$$\kappa^2 - a^{\alpha\beta} b_{\alpha\beta}\kappa + \frac{b}{a} = 0$$

or

$$\kappa^2 - \left[\frac{f_{11}}{(1+f_1^2)^{3/2}} + \frac{f_1}{u^1\sqrt{1+f_1^2}}\right]\kappa + \frac{f_1 f_{11}}{u^1(1+f_1^2)^2} = 0.$$

This is a quadratic equation in κ which gives the following two values of κ:

$$\kappa_{(1)} = \frac{f_{11}}{(1+f_1^2)^{3/2}}; \quad \kappa_{(2)} = \frac{f_1}{u^1(1+f_1^2)^{1/2}}.$$

If ρ_1 and ρ_2 be the corresponding radii of curvatures then

$$\rho_1 = \frac{1}{\kappa_{(1)}} = \frac{(1+f_1^2)^{3/2}}{f_{11}}; \quad \rho_2 = \frac{1}{\kappa_{(2)}} = \frac{u^1(1+f_1^2)^{1/2}}{f_1}.$$

The condition for the surface to be minimal is that

$$2H = \kappa_{(1)} + \kappa_{(2)} = 0$$

or

$$\frac{f_{11}}{(1+f_1^2)^{3/2}} + \frac{f_1}{u^1(1+f_1^2)^{1/2}} = 0$$

or

$$f_1(1+f_1^2) + u^1 f_{11} = 0.$$

EXAMPLE 8.2.3 Find the principal curvature of the surface defined by

$$x^1 = u^1\cos u^2; x^2 = u^1\sin u^2; \quad x^3 = a\log\left(u^1 + \sqrt{(u^1)^2 - a^2}\right).$$

Prove that it is a minimal surface and is the only minimal surface.

Solution: From example 8.2.2 we see that, the parametric representation of the surface of revolution is given by

$$x^1 = u^1\cos u^2; \; x^2 = u^1\sin u^2; \; x^3 = f(u^1);$$

where $f(u^1) = a\log\left(u^1 + \sqrt{(u^1)^2 - a^2}\right)$. Therefore,

$$f_1 = \frac{\partial f}{\partial u^1} = \frac{a}{\sqrt{(u^1)^2 - a^2}}; \; f_{11} = \frac{\partial^2 f}{(\partial u^1)^2} = -\frac{au^1}{[(u^1)^2 - a^2]^{3/2}}.$$

Therefore, $\kappa_{(1)}$ and $\kappa_{(2)}$ are given by

$$\kappa_{(1)} = \frac{f_{11}}{(1+f_1^2)^{3/2}} = -\frac{a}{(u^1)^2}; \quad \kappa_{(2)} = \frac{f_1}{u^1(1+f_1^2)^{1/2}} = \frac{a}{(u^1)^2}.$$

Since $2H = \kappa_{(1)} + \kappa_{(2)} = 0$; the surface is a minimal surface. Now, we will prove that the given surface of revolution is the minimal surface. Let the equation of any surface of revolution be

$$x^1 = u^1 \cos u^2;\ x^2 = u^1 \sin u^2;\quad x^3 = f(u^1).$$

As in example 8.2.2, the condition for the minimal surface is

$$f_1(1 + f_1^2) + u^1 f_{11} = 0$$

or

$$u^1 \frac{d^2f}{d(u^1)^2} + \frac{df}{du^1}\left[1 + \left(\frac{df}{du^1}\right)^2\right] = 0$$

or

$$\frac{dp}{p(1+p^2)} + \frac{du}{u} = 0;\quad \text{where, } p = \frac{df}{du^1}$$

or

$$\log p - \frac{1}{2}\log(1+p^2) + \log u^1 = \text{constant}$$

or

$$\frac{p^2(u^1)^2}{1+p^2} = a^2 \text{ (say)} \Rightarrow p = \frac{df}{du^1} = \frac{a}{\sqrt{(u^1)^2 - a^2}}$$

or

$$x^3 = f(u^1) = a\cosh^{-1}\frac{u^1}{a} + c_1 = a\log\left(u^1 + \sqrt{(u^1)^2 - a^2}\right) + c_1.$$

Choosing $x^3 = a \log a$ when $u^1 = a$ so that $c_1 = 0$, so,

$$x^3 = f(u^1) = a\log\left(u^1 + \sqrt{(u^1)^2 - a^2}\right)$$
$$= a\cosh^{-1}\frac{\sqrt{(x^1)^2 + (x^2)^2}}{a}$$

or

$$\sqrt{(x^1)^2 + (x^2)^2} = a\cosh\frac{x^3}{a}.$$

Thus, except for position in space, the only surface of revolution is

$$x^1 = u^1 \cos u^2;\ x^2 = u^1 \sin u^2;\quad x^3 = a\log\left(u^1 + \sqrt{(u^1)^2 - a^2}\right)$$

or $\sqrt{(x^1)^2 + (x^2)^2} = a\cosh\frac{x^3}{a}$ is the only minimal surface formed by revolution of catenary $x^1 = a\cosh\frac{x^3}{a}$ about x^1 axis, i.e. directrix.

EXAMPLE 8.2.4 Find the equation for the principal curvatures of the surface for the right helicoid.

Solution: The parametric representation of the right helicoid is given by

$$x^1 = u^1 \cos u^2;\ x^2 = u^1 \sin u^2;\ x^3 = cu^2$$

i.e.

$$r = (x^1; x^2; x^3) = \quad u^1 \cos u^2;\ u^1 \sin u^2; cu^2 \quad :$$

The symmetric covariant second order tensors a for the first fundamental form of the surface are given by

$$a_{11} = 1;\ a_{22} = (u^1)^2 + c^2 \text{ and } a_{12} = 0 = a_{21}:$$

$$) j \ a \ j = \begin{matrix} 1 & 0 \\ 0 & c^2 + (u^1)^2 \end{matrix} = c^2 + (u^1)^2:$$

The reciprocal tensors are given by

$$a^{11} = \frac{c^2 + (u^1)^2}{c^2 + (u^1)^2} = 1;\ a^{22} = \frac{1}{c^2 + (u^1)^2};\ a^{12} = 0 = a^{21}:$$

The symmetric covariant tensors b for the second fundamental form are given by

$$b_{11} = 0; b_{22} = 0 \text{ and } b_{12} = \text{p} \frac{c}{c^2 + (u^1)^2}:$$

$$) j \ b \ j = \begin{matrix} 0 & \text{p} \frac{c}{c^2+(u^1)^2} \\ \text{p} \frac{c}{c^2+(u^1)^2} & 0 \end{matrix} = \frac{c^2}{c^2 + (u^1)^2}:$$

The equation giving the principal curvatures is

$$^2 \quad a \ b \quad + \frac{b}{a} = 0$$

or

$$^2 \quad a^{11} b_{11} + a^{22} b_{22} + 2 a^{12} b_{12} \quad + \frac{b}{a} = 0$$

or

$$^2 \quad 1 \ 0 + \frac{1}{c^2 + (u^1)^2} \ 0 + 0 \quad \frac{c^2}{c^2 + (u^1)^2} \quad + \frac{b}{a} = 0$$

or

$$^2 \quad \frac{c^2}{[c^2 + (u^1)^2]^2} = 0 \ ) \quad = \frac{c}{c^2 + (u^1)^2}:$$

This is a quadratic equation in κ which gives the following two values of κ:

$$\kappa_{(1)} = \frac{c}{c^2 + (u^1)^2}; \quad \kappa_{(2)} = -\frac{c}{c^2 + (u^1)^2}.$$

Since $2H = \kappa_{(1)} + \kappa_{(2)} = 0$; the surface is a minimal surface.

EXAMPLE 8.2.5 Calculate the principal curvatures for the conicoid

$$x^1 = u^1 \cos u^2; \; x^2 = u^1 \sin u^2; \; x^3 = f(u^2);$$

where $u^1; u^2$ are parameters. Hence, find the Gaussian and the mean curvature.

Solution: The parametric representation of the surface is given by

$$\mathbf{r} = (x^1; x^2; x^3) = \left(u^1 \cos u^2; \; u^1 \sin u^2; \; f(u^2)\right).$$

The first fundamental magnitudes $a_{\alpha\beta}$ are given by

$$a_{11} = 1; \; a_{22} = (u^1)^2 + f_1^2; \; a_{12} = 0 = a_{21};$$

where $f_1 = \frac{\partial f}{\partial u^2}$. Therefore, $a = (u^1)^2 + f_1^2$. The reciprocal tensors are given by

$$a^{11} = \frac{(u^1)^2 + f_1^2}{(u^1)^2 + f_1^2} = 1; \quad a^{22} = \frac{1}{(u^1)^2 + f_1^2}; \quad a^{12} = \frac{0}{(u^1)^2 + f_1^2} = 0 = a^{21}.$$

The symmetric covariant tensors $b_{\alpha\beta}$ are given by

$$b_{11} = 0; \; b_{22} = \frac{f_1}{\sqrt{(u^1)^2 + f_1^2}}; \; b_{12} = -\frac{u^1 f_2}{\sqrt{(u^1)^2 + f_1^2}} = b_{21};$$

where $f_2 = \frac{\partial^2 f}{(\partial u^2)^2}$ so, $b = -\frac{(u^1 f_2)^2}{(u^1)^2 + f_1^2}$. The equation giving the principal curvatures is

$$\kappa^2 - a^{\alpha\beta} b_{\alpha\beta} \kappa + \frac{b}{a} = 0$$

or

$$\kappa^2 + \frac{f_1}{\{(u^1)^2 + f_1^2\}^{3/2}} \kappa - \left(\frac{u^1 f_2}{(u^1)^2 + f_1^2}\right)^2 = 0.$$

This is a quadratic equation in κ which gives the two values $\kappa_{(1)}$ and $\kappa_{(2)}$. The mean curvature H is given by

$$H = \frac{1}{2}[\kappa_{(1)} + \kappa_{(2)}] = -\frac{1}{2} \frac{f_1}{\{(u^1)^2 + f_1^2\}^{3/2}}$$

and the Gaussian curvature K is given by the formula,

$$K = \kappa_{(1)} \kappa_{(2)} = -\left(\frac{u^1 f_2}{(u^1)^2 + f_1^2}\right)^2.$$

EXAMPLE 8.2.6 Show that the surface $4c^2(x^3)^2 = ((x^1)^2 - 2c^2)((x^2)^2 - 2c^2)$ has a line of umbilic lying on the surface $(x^1)^2 + (x^2)^2 + (x^3)^2 = 4c^2.$

Solution: Let $(x^1)^2 - 2c^2 = (u^1)^2$ and $(x^2)^2 - 2c^2 = (u^2)^2$; then the parametric representation of the surface is given by

$$r = (x^1, x^2, x^3) = \left(\sqrt{2c^2 + (u^1)^2}, \sqrt{2c^2 + (u^2)^2}, \frac{u^1u^2}{2c}\right).$$

The first fundamental magnitudes $a_{\alpha\beta}$ are given by

$$a_{11} = \frac{(u^1)^2}{4c^2 + (u^1)^2} + \frac{(u^2)^2}{4c^2};\ a_{22} = \frac{(u^2)^2}{4c^2 + (u^2)^2} + \frac{(u^1)^2}{4c^2};\ a_{12} = \frac{u^1u^2}{4c^2} = a_{21},$$

where $f_1 = \frac{\partial f}{\partial u^1}$. The symmetric covariant tensors $b_{\alpha\beta}$ are given by

$$b_{11} = \frac{c(u^2)^2}{a(2c^2 + (u^1)^2)^{3/2}(2a^2 + (u^2)^2)^{1/2}},$$

$$b_{22} = \frac{c(u^1)^2}{a(2c^2 + (u^1)^2)^{1/2}(2a^2 + (u^2)^2)^{3/2}},$$

$$b_{12} = \frac{cu^2}{2ca\sqrt{(2c^2 + (u^1)^2)(2a^2 + (u^2)^2)}},$$

where $a = |a_{\alpha\beta}|$. At an umbilic, we have $\frac{b_{11}}{a_{11}} = \frac{b_{12}}{a_{12}} = \frac{b_{22}}{a_{22}}$, i.e. $b_{11}a_{22} = b_{22}a_{11}$, and so,

$$\frac{(u^1)^2}{2c^2 + (u^2)^2} + \frac{(u^2)^2}{4c^2}\ \frac{(u^1)^2}{2c^2 + (u^2)^2} = \frac{(u^2)^2}{2c^2 + (u^2)^2} + \frac{(u^1)^2}{4c^2}\ \frac{(u^2)^2}{2c^2 + (u^1)^2}$$

or

$$\frac{(u^1)^4 - (u^2)^4}{(2c^2 + (u^1)^2)(2c^2 + (u^2)^2)} + \frac{(u^1)^2(u^2)^2}{4c^2}\ \frac{1}{2c^2 + (u^2)^2} - \frac{1}{2c^2 + (u^1)^2} = 0$$

or

$$(u^1)^4 - (u^2)^4 + \frac{(u^1)^2(u^2)^2}{4c^2}\ (u^1)^2 - (u^2)^2 = 0$$

or

$$(u^1)^2 + (u^2)^2 + \frac{(u^1u^2)^2}{4c^2} = 0 \Rightarrow (x^1)^2 + (x^2)^2 + (x^3)^2 = 4c^2.$$

Thus, the umbilic lie on the surface $(x^1)^2 + (x^2)^2 + (x^3)^2 = 4c^2.$

8.2.1 Surfaces of Positive and Negative Curvatures

In order to determine the shape of a surface S in a neighbourhood of any of its points we first considered arbitrary curves on S. We enabled us to restrict of S and planes which are orthogonal to the tangent plane to S at a point P under consideration. That investigation led us to the introduction of the normal curvature [Eq. (8.14)]

$$_{(n)} = \frac{b \quad du \ du}{a \quad du \ du} = \frac{B}{A}:$$

$j\ _{(n)}j$ is the curvature of the normal section of S at P whose tangent direction is $du^2 : du^1$: We will now see that there are three different possible forms of S in a neighbourhood of a point at which the second fundamental form does not vanish identically. For this purpose we consider the behaviour of $_{(n)}$ as a function of the direction $du^2 : du^1$ of the tangent to the normal sections at P.

We know, the first fundamental form [Eq. (7.2)] is positive definite, hence the sign of $_{(n)}$ depends on the second fundamental form only.

(i) A surface is called a surface of positive curvature, if at all points, the Gaussian curvature > 0; i.e.

$$b = b_{11}b_{22} \quad b_{12}^2 > 0; \quad \text{as } a > 0 \text{ on the surface} \tag{8.25}$$

That is the second fundamental form is positive definite. In this case, $_{(n)}$ has the same sign for all possible directions of the normal sections at P, i.e. the centres of curvature of all normal sections lie on the same side of the surface S. The point P on the surface S is called elliptic. Figure 8.3 shows the shape of a surface S in the neighbourhood of an elliptic point.

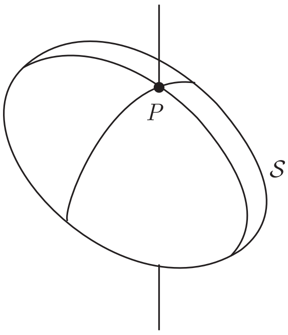

Figure 8.3: Elliptic point.

(ii) A surface is called a surface of negative curvature, if at all points, the Gaussian curvature < 0; i.e.

$$b = b_{11}b_{22} \quad b_{12}^2 < 0; \quad \text{as } a > 0 \text{ on the surface} \tag{8.26}$$

If b < 0 at a point P of a surface ${}_{(n)}$ does not maintain the same sign for all directions $du^2 : du^1$. More precisely, there exists two real asymptotic directions for which ${}_{(n)} = 0$. These directions separate the directions for which ${}_{(n)}$ is positive from which ${}_{(n)}$ is negative, P is then called a hyperbolic or saddle point of the surface S. Figure 8.4 shows the shape of a surface in the neighbourhood of a hyperbolic point.

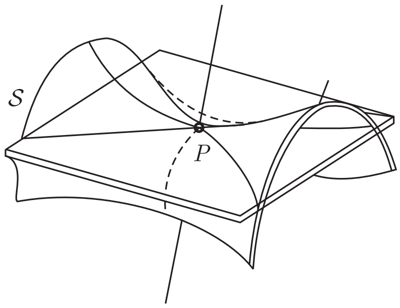

Figure 8.4: Hyperbolic point.

This figure shows also the tangent plane at that point.

(iii) If b = 0 at a point P of a surface S, ${}_{(n)}$ does not change sign, but there is exactly one direction where ${}_{(n)} = 0$; i.e. exactly one real asymptotic direction. P is then called a parabolic point or flat point or planner point of the surface S. Figure 8.5 shows the shape of a surface S in the neighbourhood of a parabolic point.

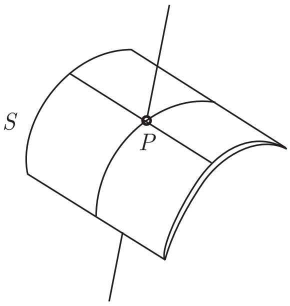

Figure 8.5: Parabolic point.

b of second fundamental form	Name	Number of real asymptotic directions	Figures
b > 0	Elliptic point	0	8.3
b = 0	Parabolic point	1	8.5
b < 0	Hyperbolic point	2	8.4

Since the conditions b >= 0 corresponds to a geometric property of the surface, they must be invariant with respect to any allowable co-ordinate transformation.

Deduction 8.2.1 Consider the section of the surface by a plane parallel and infinitely close to the tangent plane at the point P (Figure 8.6). Suppose the surface is synclastic in the neighbourhood of P. Then near P it lies entirely on one side of the tangent plane. Let the plane be taken on this (concave) side of the surface, parallel to the tangent plane at P, and at an infinitesimal distance from it, whose measure is h in the direction of the unit normal . Let the principal radii of curvature be ; , then

$$ {}_{(1)} = 1 \quad \text{and} \quad {}_{(2)} = 1: $$

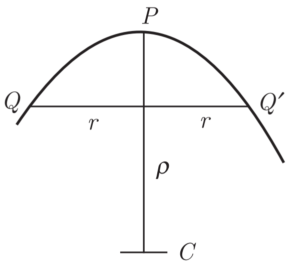

Figure 8.6: Dupin's indicatrix.

Thus, h has the same sign as and . Consider also any normal plane QPQ^0 through P, cutting the former plane in QQ^0. Then if is the radius of curvature of the normal section, and $2r$ the length of QQ^0, we have $r^2 = 2h$ to the first order. If is the inclination of the normal section to the principal direction, Euler's formula gives

$$ \frac{1}{}\cos^2 + \frac{1}{}\sin^2 = \frac{1}{} = \frac{2h}{r^2}; $$

If then we write $\& = r\cos$ and $= r\sin$, we have

$$ \frac{\&^2}{a} + \frac{{}^2}{b} = 2h: $$

Thus, the section of the surface by the plane parallel to the tangent plane at P, and indefinitely close to it, is similar and similarly situated to the ellipse

$$ \frac{\&^2}{j\ j} + \frac{{}^2}{j\ j} = 1; \tag{8.27} $$

whose axes are tangents to the lines of curvature at P. This ellipse is called the Dupin's indicatrix at the point P, and P is said to be an elliptic point. It is sometimes described as a point of positive curvature, because the second curvature is positive.

Let the principal radii, and , have opposite signs, and the surface lies partly on the other side of the tangent plane at P. In this case the Gaussian curvature is negative at P, so that the surface is anticlastic in the neighbourhood. Two planes parallel to this tangent plane, one on either side, and equidistant from it, cut the surface in the conjugate hyperbola

$$\frac{\&^2}{a} + \frac{^2}{b} = \quad 2h:$$

These are similar and similarly situated to the conjugate hyperbolas

$$\frac{\&^2}{} + \frac{^2}{} = \quad 1; \tag{8.28}$$

which constitute the indicatrix at P. The point P is then called a hyperbolic point, or a point of negative curvature. The normal curvature is zero in the directions of the asymptotes. When the Gaussian curvature is zero at the point P it is called a parabolic point. One of the principal curvatures is zero, and the indicatrix is a pair of parallel straight lines. Consequently, the principal directions bisect the angles between directions corresponding to the same normal curvature, in particular the angles between the asymptotic direction.

EXAMPLE 8.2.7 Show that the right helicoid is a surface of negative curvature.

Solution: The parametric representation of the right helicoid is given by

$$x^1 = u^1 \cos u^2;\ x^2 = u^1 \sin u^2;\ x^3 = cu^2$$

i.e.

$$r = (x^1; x^2; x^3) = \quad u^1 \cos u^2;\ u^1 \sin u^2;\ cu^2 \quad :$$

The symmetric covariant second order tensors a for the first fundamental form of the surface are given by

$$a_{11} = 1;\ \ a_{22} = (u^1)^2 + c^2 \text{ and } a_{12} = 0 = a_{21}:$$

$$\Rightarrow |\ a\ | = \begin{matrix} 1 & 0 \\ 0 & c^2 + (u^1)^2 \end{matrix} = c^2 + (u^1)^2 > 0:$$

The symmetric covariant tensors b for the second fundamental form are given by

$$b_{11} = 0;\ b_{22} = 0 \text{ and } b_{12} = \quad \frac{c}{\sqrt{c^2 + (u^1)^2}}:$$

$$\Rightarrow |\ b\ | = \begin{matrix} 0 & \frac{c}{\sqrt{c^2+(u^1)^2}} \\ \frac{c}{\sqrt{c^2+(u^1)^2}} & 0 \end{matrix} = \frac{c^2}{c^2 + (u^1)^2}:$$

Therefore, the Gaussian curvature is given by

$$= \frac{|b \quad|}{|a \quad|} = \frac{c^2}{[c^2 + (u^1)^2]^2} < 0:$$

Thus, the given surface is a surface of negative curvature.

EXAMPLE 8.2.8 Find the nature of a point on a unit sphere

$$(x^1)^2 + (x^2)^2 + (x^3)^2 = 1:$$

Solution: The parametric representation of a unit sphere is given by

$$x^1 = \cos u^1 \cos u^2; \; x^2 = \sin u^1 \cos u^2; \; x^3 = \sin u^2$$

i.e.

$$r = (x^1; x^2; x^3) = \quad \cos u^1 \cos u^2; \sin u^1 \cos u^2; \sin u^2 \quad :$$

The first fundamental magnitudes a of the surface are given by

$$a_{11} = \cos^2 u^2; \; a_{22} = 1 \text{ and } a_{12} = 0 = a_{21}:$$

$$) \quad a = |a \quad| = \begin{matrix} \cos^2 u^2 & 0 \\ 0 & 1 \end{matrix} = \cos^2 u^2 > 0:$$

The symmetric covariant tensors b for the second fundamental form are given by

$$b_{11} = \quad \cos^2 u^2; b_{12} = 0 = b_{21} \text{ and } b_{22} = \quad 1:$$

$$) \quad b = |b \quad| = \begin{matrix} \cos^2 u^2 & 0 \\ 0 & 1 \end{matrix} = \cos^2 u^2:$$

Therefore, the Gaussian curvature is given by

$$= \frac{b}{a} = \frac{\cos^2 u^2}{\cos^2 u^2} = 1 > 0:$$

Since > 0, it follows that the nature of the point on the sphere is elliptic.

8.2.2 Isometric Lines

Suppose that, in terms of the parameters $u; v$ the square of the linear element of the surface has the form

$$ds^2 = \quad (du^2 + dv^2); \tag{8.29}$$

where is a function of $u; v$ or a constant. Then the parameters curves are orthogonal because $a_{12} = 0$: Further, the lengths of elements of the parametric curves are $\sqrt{\quad} du$

and $\sqrt{\lambda}\,dv$; and these equal if $du = dv$. Thus, the parametric curves corresponding to the values $u, u + du, v, v + dv$ bound a small square provided $du = dv$. In this way the surface may be mapped out into small squares by means of the parametric curves, the sides of any one square corresponding to equal increments in u and v.

More generally, if the square of the linear element has the form

$$ds^2 = \lambda(U\,du^2 + V\,dv^2); \tag{8.30}$$

where U is a function of u only and V is a function of v only, we may change the parameters to θ, φ by the transformation

$$d\theta = \sqrt{U}\,du; \quad d\varphi = \sqrt{V}\,dv.$$

This does not alter the parametric curves; for the curves u = constant are identical with the curves θ = constant; and similarly the curves v = constant are identical with the curves φ = constant. Equation (8.30) then becomes

$$ds^2 = \lambda(d\theta^2 + d\varphi^2); \tag{8.31}$$

which is of the same form as Eq. (8.29). Whenever the square of the linear element has the form Eq. (8.30), so that, without alteration of the parametric curves, it may be reduced to the form Eq. (8.29), the parametric curves are called isometric lines, and the parameters isometric parameters.

In the form Eq. (8.29) the fundamental magnitudes a_{11} and a_{22} are equal; but in the more general form Eq. (8.30) they are such that

$$\frac{a_{11}}{a_{22}} = \frac{U}{V} \text{ and, therefore, } \frac{\partial^2}{\partial u \partial v} \log \frac{a_{11}}{a_{22}} = 0. \tag{8.32}$$

Either of these equations, in conjunction with $a_{12} = 0$, expresses the condition that the parametric variables may be isometric. If it is satisfied, ds^2 has the form Eq. (8.30) and may therefore be reduced to the form Eq. (8.29).

EXAMPLE 8.2.9 Prove that isometric curves is afforded by the meridians and parallels on a surface of revolution, given by

Solution: With the usual notation, let S is a surface of revolution, given by

$$x^1 = u\cos v; \; x^2 = u\sin v; \; x^3 = f(u); \text{ where } f(u) \in C^2.$$

The first order magnitudes are given by

$$a_{11} = 1 + f_1^2; \; a_{22} = u^2 \text{ and } a_{12} = 0 = a_{21};$$

where $f_1 = \frac{\partial f}{\partial u}$; In terms of the parameters $u; v$ the square of the linear element of the surface has the form

$$ds^2 = (1 + f_1^2)du^2 + u^2dv^2 = u^2 \quad \frac{1 + f_1^2}{u^2}du^2 + dv^2 \quad ;$$

which is of the form Eq. (8.30). The parametric curves are the meridians v = constant and the parallels u = constant. If we make the transformation

$$d\omega = \frac{1}{u}\sqrt{1 + f_1^2}\,du;$$

the curves ω = constant are the same as the parallels, and the square of the linear element becomes

$$ds^2 = u^2(d\omega^2 + dv^2);$$

which is of the form Eq. (8.29). Thus, the meridians and parallels of a surface of revolution are isometric lines.

8.3 Lines of Curvature

A curve drawn on a surface, and possessing the property that the normals to the surface at consecutive points intersect, is called a line of curvature. Thus, for a line of curvature, a curve on a surface such that the tangent line to it at every point is directed along a principal direction. The differential equation for which the lines of curvature on S are the integral curves from directly from Eq. (8.17), as

$$b \qquad = \quad {}_{(p)}a \qquad :$$

Therefore,

$$b_1 \quad = \quad {}_{(p)}a_1 \quad ; \text{ when } \quad = 1$$

$$b_2 \quad = \quad {}_{(p)}a_2 \quad ; \text{ when } \quad = 2:$$

If we eliminate ${}_{(p)}$ from these equations and set $= \frac{du}{ds}$; we get

$$\frac{b_1}{a_1}\frac{du}{du} = \frac{b_2}{a_2}\frac{du}{du}$$

or

$$(b_{11}a_{12} \quad b_{12}a_{11})(du^1)^2 + (b_{11}a_{22} \quad b_{22}a_{11})du^1du^2$$
$$+(b_{12}a_{22} \quad b_{22}a_{12})(du^2)^2 = 0: \tag{8.33}$$

This quadratic Eq. (8.33) represents the lines of curvature of the surface, showing that at every point of the surface there are two principal directions. Thus, at each point of a surface there exist two mutually orthogonal directions for which the normal curvature attains its extreme values.

It follows from the above that the direction of a line of curvature at any point is the principal direction at that point. Through each point on the surface pass two lines of curvature cutting each other at right angles; and on the surface there are two system of lines of curvature whose differential equation is Eq. (8.33).

Deduction 8.3.1 The existence of (real) asymptotic curves on a surface S depends on the geometric shape of S the lines of curvature are always real. At each point of S where either $b \quad du \quad du \neq 0$ or is not proportional to $a \quad du \quad du$, the Eq. (8.33) specifies two orthogonal directions

$$\frac{du^2}{du^1} = \quad u^1; u^2 \quad ; \quad = 1; 2; \tag{8.34}$$

which coincide with directions of the principal curvatures. Each equation in [Eq. (8.34)] determines a family of curves on S covering the surface without gaps. These two families of curves are orthogonal, and, if they are taken as a parametric net on S; the first fundamental form has the form

$$(ds)^2 = \bar{a}_{11}(d\bar{u}^1)^2 + \bar{a}_{22}(d\bar{u}^2)^2:$$

Accordingly, Eq. (8.33) in the co-ordinate system $\bar{u}$ takes the form

$$\bar{b}_{12}\bar{a}_{11}(d\bar{u}^1)^2 + (\bar{b}_{11}\bar{a}_{22} \quad \bar{b}_{22}\bar{a}_{11})d\bar{u}^1 d\bar{u}^2 + \bar{b}_{12}\bar{a}_{22}(d\bar{u}^2)^2 = 0$$

and its solutions are

$$\bar{u}^1 = \text{ constant, } \bar{u}^2 = \text{ constant.}$$

If we take $d\bar{u}^1 \neq 0$ and $d\bar{u}^2 = 0$; we see that $\bar{b}_{12} = 0$; since $\bar{a}_{11} = 0$: Thus, a necessary condition for the net of lines of curvature to be orthogonal is that $a_{12} = 0 = b_{12}$: Consequently we may always choose co-ordinates $u^1; u^2$ on S so that the lines of curvature are the co-ordinate curves of this system which is allowable at any point of S which is not umbilic. Conversely, if $a_{12} = 0 = b_{12}$, then Eq. (8.33) has the solutions u^1 = constant and u^2 = constant, so that the co-ordinate lines are the lines of curvature.

Note that, for every orthogonal net on a plane or a sphere $a_{12} = 0 = b_{12}$: Formula (8.14), for the normal curvature, when the co-ordinate system is taken to be the net of lines of curvature becomes

$$_{(n)} = \frac{b_{11}(du^1)^2 + b_{22}(du^2)^2}{a_{11}(du^1)^2 + a_{22}(du^2)^2}:$$

If we set $du^1 = 0; du^2 \neq 0$; and $du^2 = 0; du^1 \neq 0$, we get

$$_{(1)} = \frac{b_{11}}{a_{11}}; \quad _{(2)} = \frac{b_{22}}{a_{22}}$$

for the curvatures of the co-ordinate lines u^1 = constant and u^2 = constant. The lines of curvature on S should not be confused with the normal sections of S. The normal sections are necessarily plane curves, whereas the lines of curvature ordinarily are not plane curves. Thus the lines of curvature of any (real) surface S of class 3 are real curves.

Deduction 8.3.2 A point on a surface is called umbilic if at that point $b = a$, where is a scalar. In particular, if = 0, the point is called a planer point. Note that, at an umbilic point the normal curvature $_{(n)}$ is the same for all directions. If S has no umbilics the lines of curvature form an orthogonal net everywhere on S.

Theorem 8.3.1 (Rodrigue's formula): A line of curvature is characterised by

$$\frac{\partial^i}{\partial s} + {}_{(n)}\frac{dx^i}{ds} = 0;$$

where $_{(n)}$ is the principal curvature of the surface.

Proof: From Weingarten formula Eq. (7.49), we have

$$^i_{;} = a \quad b \quad x^i$$

or

$$^i_{;}\frac{du}{ds} = a \quad b \quad x^i \frac{du}{ds}$$

or

$$\frac{\partial^i}{\partial s} = a \quad b \quad x^i \quad : \tag{8.35}$$

Again, we know that for a line of curvature,

$$b = {}_{(n)}a \quad ; \text{i.e. } b = {}_{(n)}a \quad ;$$

as a and b are symmetric. Using result (8.35), we get

$$\begin{aligned}\frac{\partial^i}{\partial s} &= a \quad {}_{(n)}a \quad x^i \\ &= {}_{(n)} \quad x^i = {}_{(n)} \quad x^i \\ &= {}_{(n)}\frac{\partial u}{\partial s}\frac{\partial x^i}{\partial u} = {}_{(n)}\frac{dx^i}{ds}\end{aligned}$$

or

$$\frac{\partial^i}{\partial s} + {}_{(n)}\frac{dx^i}{ds} = 0:$$

Hence, the theorem is proved. Conversely, let the relation

$$\frac{\partial^i}{\partial s} + {}_{(n)}\frac{dx^i}{ds} = 0$$

holds. Using Weingarten formula Eq. (7.49), we have

$$\frac{\partial^i}{\partial s} = \quad a \quad b \quad x^i$$

or

$$a \quad b \quad x^i \quad + {}_{(n)}\frac{dx^i}{ds} = 0:$$

Taking the inner product with $g_{ik}x^k_p$, we get

$$a \quad b \quad g_{ik}x^k_p x^i \quad + {}_{(n)}g_{ik}x^k_p\frac{dx^i}{ds} = 0$$

or

$$a \quad b \quad a_p \quad + {}_{(n)}g_{ki}x^i_p\frac{dx^k}{ds} = 0:$$

Interchanging the dummy indices i and k in the second term, we get

$$b_p \quad + {}_{(n)}g_{ik}x^i_p\frac{\partial x^k}{\partial u}\frac{du}{ds} = 0$$

or

$$b_p \quad + {}_{(n)}g_{ik}x^i_p x^k \quad = 0$$

or

$$b_p \quad + {}_{(n)}a_p \quad = 0$$

or

$${}_{(n)}a_p \quad b_p \quad = 0;$$

which is the equation of the line of curvature. The Rodrigues formulae are characteristic for the lines of curvature.

EXAMPLE 8.3.1 Show that the parametric curves are the lines of curvature if and only if $a_{12} = 0 = b_{12}$:

Solution: Let us assume that the parametric curves be the lines of curvature. Then they form an orthogonal net and will satisfy Eq. (8.33). Now, for u^1 curve, $du^2 = 0$ and hence from Eq. (8.33), we get

$$b_{11}a_{12} - a_{11}b_{12} = 0; \quad \text{as } du^1 \neq 0$$

and for u^2 curve, $du^1 = 0$ and hence from Eq. (8.33), we get

$$b_{12}a_{22} - a_{12}b_{22} = 0; \quad \text{as } du^2 \neq 0.$$

Multiplying first equation by $-a_{22}$ and second by a_{11} and adding, we get

$$a_{12}(a_{22}b_{11} - a_{11}b_{22}) = 0$$

$$\Rightarrow \quad \text{either } a_{12} = 0 \text{ or } \frac{a_{11}}{b_{11}} = \frac{a_{22}}{b_{22}}.$$

For the parametric curve, $a_{22}b_{11} \neq a_{11}b_{22}$ and so $a_{12} = 0$. The condition $a_{12} = 0$ is that of orthogonality satisfied by all lines of curvature. Similarly, multiplying first equation by b_{22} and second by b_{11} and adding, we get

$$b_{12}(a_{22}b_{11} - a_{11}b_{22}) = 0 \Rightarrow b_{12} = 0.$$

Thus $b_{12} = 0$, is the necessary and sufficient condition that the parametric curves form a conjugate system. Conversely, let $a_{12} = 0 = b_{12}$, then Eq. (8.33) reduces to

$$(a_{22}b_{11} - a_{11}b_{22})\, du^1 du^2 = 0.$$

If the lines of curvature exist, then $a_{22}b_{11} - a_{11}b_{22} \neq 0$ and the curves are the solution of the equation $du^1 du^2 = 0$. Hence,

$$\text{when} \quad du^1 \neq 0; \quad du^2 = 0 \Rightarrow u^2 = \text{constant}.$$

$$\text{when} \quad du^2 \neq 0; \quad du^1 = 0 \Rightarrow u^1 = \text{constant}.$$

Hence, the parametric curves are the lines of curvature. Thus, if in particular the co-ordinates are chosen so that the co-ordinate curves are lines of curvature on the surface S then $a_{12} = b_{12} = 0$ and therefore the Rodrigues formulae becomes

$$\frac{\partial^i}{\partial S} = -\frac{b_i}{a_{ii}} \frac{dx^i}{ds} \text{(no summation)}; \; i = 1, 2.$$

EXAMPLE 8.3.2 Show that the lines of curvature on a minimal surface form an isometric systems.

Solution: If the parametric curves are the lines of curvature, then $a_{12} = 0 = b_{12}$. Now, for the minimal surface,

$$H = \frac{1}{2} a^{\alpha\beta} b_{\alpha\beta} = 0$$

$$\Rightarrow H = \frac{1}{2a}[a_{22}b_{11} + a_{11}b_{22}] = 0; \quad \text{as } a_{12} = 0 = b_{12}$$

$$\Rightarrow b_{11} = b_{22} = 0; \quad \text{as } a \neq 0$$

$$\Rightarrow b_{\alpha\beta} = 0.$$

Therefore, the surface is a plane, i.e. the surface is isomorphic with Euclidean plane.

Theorem 8.3.2 (Euler's theorem on normal curvature): If the lines of curvature are not indeterminant at a given point P on the surface and if θ is the angle between a given direction and a principal direction at P, then the normal curvature is given by the formula

$$\kappa_{(n)} = \kappa_{(1)} \cos^2\theta + \kappa_{(2)} \sin^2\theta.$$

Proof: We assume that P is not an umbilic. If the parametric curves are taken as the lines of curvature, then the principal curvatures are given by

$$\kappa_{(1)} = \frac{b_{11}}{a_{11}} \text{ and } \kappa_{(2)} = \frac{b_{22}}{a_{22}}.$$

Let θ be the angle between a given direction (u^1, u^2) and a principal direction at a given point P. Since the co-ordinate curves are orthogonal, we have

$$\cos\theta = \sqrt{a_{11}}\frac{du^1}{ds} \text{ and } \sin\theta = \sqrt{a_{22}}\frac{du^2}{ds}.$$

Also, let $\kappa_{(1)}, \kappa_{(2)}$ be the principal curvatures at P. If the parametric curves are taken as lines of curvature, then the normal curvature at P is given by

$$\kappa_{(n)} = \frac{b_{11}(du^1)^2 + b_{22}(du^2)^2}{ds^2} = b_{11}\left(\frac{du^1}{ds}\right)^2 + b_{22}\left(\frac{du^2}{ds}\right)^2$$

$$= \frac{b_{11}}{a_{11}}\cos^2\theta + \frac{b_{22}}{a_{22}}\sin^2\theta = \kappa_{(1)}\cos^2\theta + \kappa_{(2)}\sin^2\theta.$$

This is Euler's theorem on normal curvature. This theorem tells us that, the normal curvature corresponding to any direction can be simply represented in terms of the principal curvatures. The Gaussian and total curvature in this case is given by

$$K = \frac{b_{11}}{a_{11}}\frac{b_{22}}{a_{22}} \text{ and } H = \frac{1}{2}\left(\frac{b_{11}}{a_{11}} + \frac{b_{22}}{a_{22}}\right).$$

From this we conclude the lines of curvature on a minimal surface form an isometric system.

Deduction 8.3.3 Let $_{(n_1)}$ and $_{(n_2)}$ denote normal curvatures in two orthogonal directions on the surface and be the angle between the first direction $du^2 = 0$; thus, the angle between the second direction and the principal direction $du^1 = 0$ will be $\frac{}{2} +$. Thus, from Euler's theorem, we have

$$_{(n_1)} = \ _{(1)} \cos^2 \ + \ _{(2)} \sin^2 \ ;$$

$$_{(n_2)} = \ _{(1)} \cos^2 \ \frac{}{2} + \ \ + \ _{(2)} \sin^2 \ \frac{}{2} +$$

$$= \ _{(1)} \sin^2 \ + \ _{(2)} \cos^2 \ :$$

Now, adding, we get

$$_{(n_1)} + \ _{(n_2)} = \ _{(1)} + \ _{(2)} :$$

Thus, the sum of the normal curvatures in two orthogonal directions is equal to the sum of the principal curvatures at that point. This is known as Dupin's theorem.

Result: The theorem of enter and the theorem of Meusnier give complete information on the curvature of any curve on a surface.

EXAMPLE 8.3.3 Find the equations for the lines of curvature for the surface given by $r = (u \cos v; u \sin v; cv)$:

Solution: For the given surface, the symmetric covariant second order tensors a for the first fundamental form are given by

$$a_{11} = 1; \ a_{22} = u^2 + c^2; \ a_{12} = 0 = a_{21};$$

and the second fundamental magnitudes b are given by

$$b_{11} = 0; \ b_{22} = 0; \ b_{12} = \ \frac{c}{\sqrt{u^2 + c^2}} = b_{21}:$$

Since $a_{12} = 0 = b_{12}$, this given parametric curve has the line of curvature. The lines of curvature are given by

$$(b_{11}a_{12} \quad b_{12}a_{11})(du)^2 + (b_{11}a_{22} \quad b_{22}a_{11})du \ dv$$
$$+(b_{12}a_{22} \quad b_{22}a_{12})(dv)^2 = 0$$

or

$$b_{12}a_{11}(du)^2 + b_{12}a_{22})(dv)^2 = 0$$

or

$$\frac{c}{\sqrt{u^2+c^2}}(du)^2 - \frac{c}{\sqrt{u^2+c^2}}(u^2+c^2)(dv)^2 = 0$$

or

$$\frac{du}{\sqrt{u^2+c^2}} = \pm dv \Rightarrow v = \pm \sinh^{-1}\frac{u}{c} + k,$$

where k is a constant.

EXAMPLE 8.3.4 Given an ellipsoid of revolution, whose surface is determined by

$$x^1 = a\cos u^1 \sin u^2;\quad x^2 = a \sin u^1 \sin u^2; x^3 = c\cos u^2$$

where $a^2 > c^2$. Find $a_{\alpha\beta}$, $b_{\alpha\beta}$ and $\kappa = \kappa_{(1)}\kappa_{(2)}$. Discuss the lines of curvature.

Solution: The parametric representation of the ellipsoid of revolution is given by

$$x^1 = a\cos u^1 \sin u^2; x^2 = a\sin u^1 \sin u^2; x^3 = c\cos u^2$$

i.e.

$$\mathbf{r} = (x^1, x^2, x^3) = \left(a\cos u^1 \sin u^2, a\sin u^1 \sin u^2, c\cos u^2\right).$$

The symmetric covariant second order tensors $a_{\alpha\beta}$ for the first fundamental form of the surface of the ellipsoid of revolution are given by

$$a_{11} = \left(\frac{\partial x^1}{\partial u^1}\right)^2 + \left(\frac{\partial x^2}{\partial u^1}\right)^2 + \left(\frac{\partial x^3}{\partial u^1}\right)^2$$

$$= (-a\sin u^1 \sin u^2)^2 + (a\cos u^1 \sin u^2)^2 + 0^2 = a^2 \sin^2 u^2.$$

$$a_{22} = \left(\frac{\partial x^1}{\partial u^2}\right)^2 + \left(\frac{\partial x^2}{\partial u^2}\right)^2 + \left(\frac{\partial x^3}{\partial u^2}\right)^2$$

$$= (a\cos u^1 \cos u^2)^2 + (a\sin u^1 \cos u^2)^2 + (-c\sin u^2)^2$$

$$= a^2\cos^2 u^2 + c^2 \sin^2 u^2.$$

$$a_{12} = \frac{\partial x^1}{\partial u^1}\frac{\partial x^1}{\partial u^2} + \frac{\partial x^2}{\partial u^1}\frac{\partial x^2}{\partial u^2} + \frac{\partial x^3}{\partial u^1}\frac{\partial x^3}{\partial u^2} = 0 = a_{21}.$$

Therefore,

$$a = \begin{vmatrix} a^2\sin^2 u^2 & 0 \\ 0 & a^2\cos^2 u^2 + c^2\sin^2 u^2 \end{vmatrix} = a^2 \sin^2 u^2 (a^2\cos^2 u^2 + c^2 \sin^2 u^2).$$

To calculate the tensors of second fundamental form, we have

$$\mathbf{A} = (-a\sin u^1 \sin u^2, a\cos u^1 \sin u^2, 0) \text{ and}$$

$$\mathbf{B} = (a\cos u^1 \cos u^2, a\sin u^1 \cos u^2, -c\sin u^2)$$

$$\mathbf{A} \times \mathbf{B} = \left(-ac\cos u^1 \sin u^2, ac\sin u^1 \sin u^2, -a^2 \sin u^2 \cos u^2\right).$$

The normal vector is given by

$$= \frac{1}{\sqrt{a^2\cos^2 u^2 + c^2\sin^2 u^2}} \quad ac\cos u^1 \sin u^2; ac\sin u^1 \sin u^2; \quad a^2 \sin u^2 \cos u^2 \; :$$

Thus, the covariant tensors b for the second fundamental form are given by

$$b_{11} = \frac{ac\sin^2 u^2}{\sqrt{a^2\cos^2 u^2 + c^2\sin^2 u^2}}; b_{22} = \frac{ac}{\sqrt{a^2\cos^2 u^2 + c^2\sin^2 u^2}}; \; b_{12} = 0:$$

$$) \quad b = b_{11}b_{22} \quad b_{12}^2 = \frac{a^2c^2\sin^2 u^2}{a^2\cos^2 u^2 + c^2\sin^2 u^2}:$$

Therefore, the Gaussian curvature is given by

$$= \frac{b}{a} = \frac{a^2c^2\sin^2 u^2}{a^2\cos^2 u^2 + c^2\sin^2 u^2} \quad \frac{1}{a^2\sin^2 u^2(a^2\cos^2 u^2 + c^2\sin^2 u^2)}$$

$$= \frac{c^2}{a^2\cos^2 u^2 + c^2\sin^2 u^2 \;\; ^2}:$$

Since $a_{12} = 0; b_{12} = 0$; so the equation of the lines of curvature is given by

$$(b_{11}a_{22} \quad b_{22}a_{11})\, du^1 du^2 = 0;$$

$$(a^2 \quad c^2)\sin^4 u^2 du^1 du^2 = 0:$$

EXAMPLE 8.3.5 Show that any curve on a sphere is a line of curvature.

Solution: The parametric representation of the sphere of radius a is given by

$$x^1 = a\sin u^1 \cos u^2; \quad x^2 = a\sin u^1 \sin u^2; x^3 = a\cos u^2$$

i.e.

$$r = (x^1; x^2; x^3) = \quad a\sin u^1 \cos u^2; a\sin u^1 \sin u^2; a\cos u^2 \; :$$

For the given surface, the symmetric covariant second order tensors a for the first fundamental form are given by

$$a_{11} = a^2; \; a_{22} = a^2\sin^2 u^1; \; a_{12} = 0 = a_{21}$$

and the symmetric covariant second order tensors b for the second fundamental form are given by

$$b_{11} = \quad a; \; b_{22} = \quad a\sin^2 u^1; \; b_{12} = 0 = b_{21}:$$

Since $a_{12} = 0 = b_{12}$, this given parametric curve has the line of curvature. In fact,

$$\frac{b_{11}}{a_{11}} = \frac{b_{12}}{a_{12}} = \frac{b_{22}}{a_{22}} = -\frac{1}{a},$$

i.e. $b_{\alpha\beta}$ are proportional to $a_{\alpha\beta}$. Now,

$$\begin{aligned}&(b_{11}a_{12} - b_{12}a_{11})(du^1)^2 + (b_{11}a_{22} - b_{22}a_{11})du^1du^2\\ &\quad + (b_{12}a_{22} - b_{22}a_{12})(du^2)^2 = \left[-a^3\sin^2 u^1 + a^3\sin^2 u^1\right] du^1du^2 = 0.\end{aligned}$$

This shows that the equation of the lines of curvature reduces to an identity. Hence, any curve on a sphere is a line of curvature.

EXAMPLE 8.3.6 Given a surface of revolution S

$$x^1 = u^1\cos u^2,\; x^2 = u^1\sin u^2,\; x^3 = f(u^1)$$

with $f(u^1)$ of class C^2. Prove that the lines of curvature on S are the meridians $u^2 =$ constant and the parallels $u^1 =$ constant.

Solution: The parametric representation of the right helicoid is given by

$$x^1 = u^1\cos u^2,\; x^2 = u^1\sin u^2,\; x^3 = f(u^1)$$

i.e.

$$\vec{r} = (x^1, x^2, x^3) = \left(u^1\cos u^2,\; u^1\sin u^2,\; f(u^1)\right).$$

The symmetric covariant second order tensors $a_{\alpha\beta}$ for the first fundamental form of the surface are given by

$$a_{11} = 1 + f_1^2;\quad a_{22} = (u^1)^2 \text{ and } a_{12} = 0 = a_{21}$$

$$\Rightarrow\quad a = \begin{vmatrix} 1 + f_1^2 & 0 \\ 0 & (u^1)^2 \end{vmatrix} = (u^1)^2(1 + f_1^2),$$

where $f_1 = \frac{\partial f}{\partial u^1}$. The symmetric covariant tensors $b_{\alpha\beta}$ for the second fundamental form are given by

$$b_{11} = \frac{f_{11}}{\sqrt{1 + f_1^2}},\; b_{22} = \frac{u^1 f_1}{\sqrt{1 + f_1^2}} \text{ and } b_{12} = 0 = b_{21}.$$

$$\Rightarrow |b_{\alpha\beta}| = \begin{vmatrix} \frac{f_{11}}{\sqrt{1 + f_1^2}} & 0 \\ 0 & \frac{u^1 f_1}{\sqrt{1 + f_1^2}} \end{vmatrix} = \frac{u^1 f_1 f_{11}}{1 + f_1^2},$$

where $f_1 = \frac{\partial f}{\partial u^1}$ and $f_{11} = \frac{\partial^2 f}{\partial u^1 \partial u^1}$. Equation (8.33) giving the principal curvatures is

$$(b_{11}a_{12} - b_{12}a_{11})(du^1)^2 + (b_{11}a_{22} - b_{22}a_{11})du^1du^2$$
$$+(b_{12}a_{22} - b_{22}a_{12})(du^2)^2 = 0$$

or

$$\left[-\left(1 + f_1^2\right)\frac{u^1 f_1}{\sqrt{1 + f_1^2}} + \left(u^1\right)^2 \frac{f_{11}}{\sqrt{1 + f_1^2}}\right] du^1du^2 = 0$$

or

$$du^1du^2 = 0 \Rightarrow u^2 = \text{constant, or, } u^1 = \text{constant}.$$

EXAMPLE 8.3.7 Find the differential equation of lines of curvature of the helicoid

$$x^1 = u^1 \cos u^2;\; x^2 = u^1 \sin u^2;\; x^3 = f(u^1) + cu^2,$$

where u^1, u^2 are parameters.

Solution: The parametric representation of the surface is given by

$$\mathbf{r} = (x^1, x^2, x^3) = \left(u^1 \cos u^2,\; u^1 \sin u^2,\; f(u^1) + cu^2\right).$$

The first fundamental magnitudes $a_{\alpha\beta}$ are given by

$$a_{11} = \left(\frac{\partial x^1}{\partial u^1}\right)^2 + \left(\frac{\partial x^2}{\partial u^1}\right)^2 + \left(\frac{\partial x^3}{\partial u^1}\right)^2 = 1 + f_1^2;$$
$$a_{22} = \left(\frac{\partial x^1}{\partial u^2}\right)^2 + \left(\frac{\partial x^2}{\partial u^2}\right)^2 + \left(\frac{\partial x^3}{\partial u^2}\right)^2 = (u^1)^2 + c^2;$$
$$a_{12} = \frac{\partial x^1}{\partial u^1}\frac{\partial x^1}{\partial u^2} + \frac{\partial x^2}{\partial u^1}\frac{\partial x^2}{\partial u^2} + \frac{\partial x^3}{\partial u^1}\frac{\partial x^3}{\partial u^2} = cf_1 = a_{21},$$

where $f_1 = \frac{\partial f}{\partial u^1}$. Therefore,

$$a = \begin{vmatrix} 1 + f_1^2 & cf_1 \\ cf_1 & (u^1)^2 + c^2 \end{vmatrix} = (u^1)^2(1 + f_1^2) + c^2.$$

The reciprocal tensors are given by

$$a^{11} = \frac{(u^1)^2 + c^2}{(u^1)^2(1 + f_1^2) + c^2};\; a^{22} = \frac{1 + f_1^2}{(u^1)^2(1 + f_1^2) + c^2};$$
$$a^{12} = \frac{-cf_1}{(u^1)^2(1 + f_1^2) + c^2} = a^{21}.$$

Since $r = (x^1; x^2; x^3) = \quad u^1 \cos u^2; \quad u^1 \sin u^2; \quad f(u^1) + cu^2$, we have

$$A = (\cos u^2; \sin u^2; f_1) \text{ and } B = (\quad u^1 \sin u^2; u^1 \cos u^2; c)$$

$$A \quad B = (c \sin u^2 \quad u^1 f_1 \cos u^2)\hat{\imath} + (\quad c \cos u^2 \quad u^1 f_1 \sin u^2)\hat{\jmath} + u^1\hat{k}:$$

Therefore, the unit normal vector is given by

$$= \frac{1}{\sqrt{(u^1)^2(1+f_1^2)+c^2}} \quad c \sin u^2 \quad u^1 f_1 \cos u^2; \quad c \cos u^2 \quad u^1 f_1 \sin u^2; u^1 \quad :$$

The symmetric covariant tensors b are given by

$$b_{11} = \frac{u^1 f_2}{\sqrt{(u^1)^2(1+f_1^2)+c^2}}; b_{22} = \frac{(u^1)^2 f_1}{\sqrt{(u^1)^2(1+f_1^2)+c^2}}; b_{12} = \frac{c}{\sqrt{(u^1)^2(1+f_1^2)+c^2}};$$

where $f_2 = \frac{\partial^2 f}{(\partial u^1)^2}$: Therefore,

$$b = \begin{matrix} \frac{u^1 f_2}{\sqrt{(u^1)^2(1+f_1^2)+c^2}} & \frac{c}{\sqrt{(u^1)^2(1+f_1^2)+c^2}} \\ \frac{c}{\sqrt{(u^1)^2(1+f_1^2)+c^2}} & \frac{(u^1)^2 f_1}{\sqrt{(u^1)^2(1+f_1^2)+c^2}} \end{matrix} = \frac{(u^1)^3 f_1 f_2 \quad c^2}{(u^1)^2(1+f_1^2)+c^2}:$$

The equation giving the principal curvatures is

$${}^2 \quad a \quad b \qquad + \frac{b}{a} = 0$$

or

$${}^2 + \quad '' \frac{(1+f_1^2)(u^1)^2 f_1 + 2c^2 f_1 + ((u^1)^2 + c^2)u^1 f_2}{(u^1)^2(1+f_1^2)+c^2 \quad ^{3=2}} \# \qquad + \frac{(u^1)^3 f_1 f_2 \quad c^2}{(u^1)^2(1+f_1^2)+c^2 \quad ^2} = 0:$$

This is a quadratic equation in giving the two values $_{(1)}$ and $_{(2)}$. The mean curvature H is given by

$$H = \frac{1}{2}[\; _{(1)} + \; _{(2)}] = \frac{1}{2} \quad '' \frac{(1+f_1^2)(u^1)^2 f_1 + 2c^2 f_1 + ((u^1)^2 + c^2)u^1 f_2}{(u^1)^2(1+f_1^2)+c^2 \quad ^{3=2}} \#$$

and the Gaussian curvature is given by the formula,

$$= \; _{(1)} \; _{(2)} = \frac{(u^1)^3 f_1 f_2 \quad c^2}{(u^1)^2(1+f_1^2)+c^2 \quad ^2}:$$

From this relation, we see that, along the helix u^1 = constant, the value of is constant and is independent of parameter u^2. The differential equation giving the directions of the lines of curvatures is

$$(b_{11}a_{12} - b_{12}a_{11})(du^1)^2 + (b_{11}a_{22} - b_{22}a_{11})du^1du^2 + (b_{12}a_{22} - b_{22}a_{12})(du^2)^2 = 0$$

or

$$c[u^1 f_1 f_2 + 1 + f_1^2](du^1)^2 + [u^1 f_2 f(u^1)^2 + c^2 g - (u^1)^2 f_1(1 + f_1^2)]du^1du^2 - c[(u^1)^2(1 + f_1^2) + c^2](du^2)^2 = 0.$$

If the meridians are lines of curvature, i.e. curves u^2 = constant are lines of curvature then $du^2 = 0$ and so, we get

$$c[u^1 f_1 f_2 + 1 + f_1^2](du^1)^2 = 0$$

or

$$u^1 f_1 f_2 + 1 + f_1^2 = 0 \text{ as } c \neq 0;\ du^1 \neq 0;$$

which is the required condition for the meridians to be lines of curvatures.

EXAMPLE 8.3.8 Prove that the line of curvature of the paraboloid $x^1x^2 = ax^3$ lie on the surface

$$\sinh^{-1}\frac{x^1}{a} - \sinh^{-1}\frac{x^2}{a} = c;$$

where c is an constant. Hence find the equation of the cone passes through a line of curvature of the paraboloid $x^1x^2 = ax^3$.

Solution: If the parameter x^3 can be written in the form

$$x^3 = f(x^1; x^2) = \frac{x^1x^2}{a}$$

then the parametric equation of the paraboloid $x^1x^2 = ax^3$ can be written in the form

$$r = (x^1; x^2; x^3) = \{x^1; x^2; f(x^1; x^2)\}:$$

The first fundamental magnitudes a are given by

$$a_{11} = \left(\frac{\partial x^1}{\partial u^1}\right)^2 + \left(\frac{\partial x^2}{\partial u^1}\right)^2 + \left(\frac{\partial x^3}{\partial u^1}\right)^2 = 1 + f_1^2;$$

$$a_{22} = \left(\frac{\partial x^1}{\partial u^2}\right)^2 + \left(\frac{\partial x^2}{\partial u^2}\right)^2 + \left(\frac{\partial x^3}{\partial u^2}\right)^2 = 1 + f_2^2;$$

$$a_{12} = \frac{\partial x^1}{\partial u^1}\frac{\partial x^1}{\partial u^2} + \frac{\partial x^2}{\partial u^1}\frac{\partial x^2}{\partial u^2} + \frac{\partial x^3}{\partial u^1}\frac{\partial x^3}{\partial u^2} = f_1 f_2 = a_{21};$$

where $f_1 = \frac{\partial f}{\partial u^1}$ and $f_2 = \frac{\partial f}{\partial u^2}$. Therefore,

$$a = \begin{vmatrix} 1+f_1^2 & f_1 f_2 \\ f_1 f_2 & 1+f_2^2 \end{vmatrix} = 1 + f_1^2 + f_2^2.$$

Since $r = \left(x^1, x^2, f(x^1, x^2)\right)$, we have $A = (1, 0, f_1)$ and $B = (0, 1, f_2)$

$$A \times B = -f_1 \hat{i} - f_2 \hat{j} + \hat{k}.$$

Therefore, the unit normal vector ξ is given by

$$\xi = \frac{1}{\sqrt{1+f_1^2+f_2^2}}(-f_1, -f_2, 1).$$

The symmetric covariant tensors $b_{\alpha\beta}$ are given by

$$b_{11} = \frac{f_{11}}{\sqrt{1+f_1^2+f_2^2}}; \quad b_{22} = \frac{f_{22}}{\sqrt{1+f_1^2+f_2^2}}; \quad b_{12} = \frac{f_{12}}{\sqrt{1+f_1^2+f_2^2}};$$

where $f_{ij} = \frac{\partial^2 f}{\partial u^i \partial u^j}$. Therefore,

$$b = \begin{vmatrix} \frac{f_{11}}{\sqrt{1+f_1^2+f_2^2}} & \frac{f_{12}}{\sqrt{1+f_1^2+f_2^2}} \\ \frac{f_{12}}{\sqrt{1+f_1^2+f_2^2}} & \frac{f_{22}}{\sqrt{1+f_1^2+f_2^2}} \end{vmatrix} = \frac{f_{11} f_{22} - f_{12}^2}{1+f_1^2+f_2^2}.$$

The differential equation giving the directions of the lines of curvatures is

$$(b_{11}a_{12} - b_{12}a_{11})(dx^1)^2 + (b_{11}a_{22} - b_{22}a_{11})dx^1 dx^2 + (b_{12}a_{22} - b_{22}a_{12})(dx^2)^2 = 0$$

or

$$\frac{1}{a}\left(1 + \frac{(x^2)^2}{a^2}\right)(dx^1)^2 - \frac{1}{a}\left(1 + \frac{(x^1)^2}{a^2}\right)(dx^2)^2 = 0$$

or

$$\frac{dx^1}{\sqrt{a^2 + (x^1)^2}} - \frac{dx^2}{\sqrt{a^2 + (x^2)^2}} = 0$$

or

$$\sinh^{-1}\frac{x^1}{a} - \sinh^{-1}\frac{x^2}{a} = c;$$

where c is a constant. This equation can be written as

$$\sinh^{-1}\left[\frac{x^1}{a}\sqrt{1 + \frac{(x^2)^2}{a^2}} - \frac{x^2}{a}\sqrt{1 + \frac{(x^1)^2}{a^2}}\right] = c$$

or

$$\frac{x^1}{a}\sqrt{1+\frac{(x^2)^2}{a^2}} - \frac{x^2}{a}\sqrt{1+\frac{(x^1)^2}{a^2}} = \sinh c = p;\ \text{(say)}$$

or

$$\frac{x^3}{x^2}\sqrt{1+\frac{(x^3)^2}{(x^1)^2}} - \frac{x^3}{x^1}\sqrt{1+\frac{(x^3)^2}{(x^2)^2}} = p$$

or

$$x^3\left[\sqrt{(x^1)^2+(x^3)^2} - \sqrt{(x^2)^2+(x^3)^2}\right] = px^1x^2.$$

This is a homogeneous second degree equation and hence represents a cone passes through the paraboloid $x^1x^2 = ax^3$.

EXAMPLE 8.3.9 Find the principal directions and the principal curvatures on the surface

$$x^1 = a(u^1+u^2);\ x^2 = b(u^1-u^2);\ x^3 = u^1u^2.$$

Solution: The parametric representation of the surface is given by

$$\vec{r} = (x^1; x^2; x^3) = \left(a(u^1+u^2);\ b(u^1-u^2);\ u^1u^2\right).$$

The first fundamental magnitudes $a_{\alpha\beta}$ are given by

$$a_{11} = \left(\frac{\partial x^1}{\partial u^1}\right)^2 + \left(\frac{\partial x^2}{\partial u^1}\right)^2 + \left(\frac{\partial x^3}{\partial u^1}\right)^2 = a^2+b^2+\left(u^2\right)^2.$$

$$a_{22} = \left(\frac{\partial x^1}{\partial u^2}\right)^2 + \left(\frac{\partial x^2}{\partial u^2}\right)^2 + \left(\frac{\partial x^3}{\partial u^2}\right)^2 = a^2+b^2+\left(u^1\right)^2.$$

$$a_{12} = \frac{\partial x^1}{\partial u^1}\frac{\partial x^1}{\partial u^2} + \frac{\partial x^2}{\partial u^1}\frac{\partial x^2}{\partial u^2} + \frac{\partial x^3}{\partial u^1}\frac{\partial x^3}{\partial u^2} = a^2-b^2+u^1u^2 = a_{21}.$$

Therefore,

$$\Delta = 4a^2b^2 + a^2\left(u^1-u^2\right)^2 + b^2(u^1+u^2)^2.$$

The reciprocal tensors are given by

$$a^{11} = \frac{a^2+b^2+\left(u^1\right)^2}{\Delta};\quad a^{22} = \frac{a^2+b^2+\left(u^2\right)^2}{\Delta};\quad a^{12} = -\frac{a^2-b^2+u^1u^2}{\Delta} = a^{21}.$$

Since $\vec{r} = (x^1; x^2; x^3) = \left(a(u^1+u^2);\ b(u^1-u^2);\ u^1u^2\right)$, we have

$$\vec{A} = (a; b; u^2) \text{ and } \vec{B} = (a; -b; u^1)$$

$$\vec{A}\times\vec{B} = \left(b(u^1+u^2); a(u^2-u^1); -2ab\right).$$

Therefore, the unit normal vector   is given by

$$= \frac{1}{p\overline{4}} \quad b(u^1 + u^2);\; a(u^2 \quad u^1); \quad 2ab \;:$$

The symmetric covariant tensors b   are given by

$$b_{11} = \frac{@}{@u^1}\;\frac{@}{@u^1} = 0;\quad b_{22} = \frac{@}{@u^2}\;\frac{@}{@u^2} = 0;\quad b_{12} = \frac{2ab}{p\overline{4}}:$$

$$\text{Therefore, } b = \frac{4a^2b^2}{4}:$$

The equation giving the principal curvatures is

$$^2 \quad a \quad b \qquad + \frac{b}{4} = 0$$

or

$$^2 \quad \frac{4ab}{4^{3=2}}\; a^2 \quad b^2 + u^1u^2 \qquad \frac{4a^2b^2}{4^{\;2}} = 0:$$

This is a quadratic equation in   giving the two values $_{(1)}$ and $_{(2)}$. The rst curvature H is given by,

$$H = \frac{1}{2}[\;_{(1)} + \;_{(2)}] = \frac{2ab}{4^{3=2}}\; a^2 \quad b^2 + u^1u^2$$

and the speci c curvature   is given by the formula,

$$= \;_{(1)}\;_{(2)} = \frac{4a^2b^2}{4^{\;2}}:$$

The di erential equation giving the directions of the lines of curvatures is

$$(b_{11}a_{12} \quad b_{12}a_{11})(du^1)^2 + (\,b_{11}a_{22} \quad b_{22}a_{11})du^1du^2$$
$$+(\,b_{12}a_{22} \quad b_{22}a_{12})(du^2)^2 = 0$$

or

$$h\; a^2 + b^2 + \quad u^2\;{}^2\; i\; (du^1)^2 \qquad h\; a^2 + b^2 + \quad u^1\;{}^2\; i\; (du^2)^2 = 0$$

or

$$\frac{du^1}{q\overline{a^2 + b^2 + (\,u^1)^2}} = \frac{du^2}{q\overline{a^2 + b^2 + (\,u^2)^2}}$$

or

$$\log \quad u^1 + \quad q\overline{a^2 + b^2 + (\,u^1)^2} \quad = \quad \log \quad u^2 + \quad q\overline{a^2 + b^2 + (\,u^2)^2} \quad + C:$$

8.3.1 Null Lines

The null lines (or minimal curves) on a surface are defined as the curves of zero length. Therefore, they are imaginary on a real surface, and their importance is chiefly analytic. The differential equation of the null lines is obtained by equating to zero the square of the line element. It is therefore,

$$a_{11}du^2 + 2a_{12}dudv + a_{22}dv^2 = 0: \tag{8.36}$$

If the parametric curves are null lines, this equation must be equivalent to $dudv = 0$: Hence $a_{11} = 0; a_{12} = 0$ and $a_{12} \neq 0$: These are the necessary and sufficient conditions that the parametric curves be null lines. In this case the square of the line element has the form $ds^2 = \ dudv$; where is a function of $u; v$ or a constant; and the parameters $u; v$ are then said to be symmetric.

When the parametric curves are null lines, so that $a_{11} = 0; a_{22} = 0$, $a = \ a_{12}^2$; the differential equation of the lines of curvature is

$$b_{11}du^2 \quad b_{22}dv^2 = 0:$$

Therefore, the Gauss curvature and the mean curvature H are, respectively, given by

$$= \frac{b_{11}b_{22} \quad b_{12}^2}{a_{12}^2}; \; H = \frac{2b_{12}}{a_{12}}:$$

8.3.2 Conjugate Directions

Let Q be a point on the surface adjacent to P, and let PR be the line of intersection of the tangent plane at P and Q. Then, as Q tends to coincidence with P, the limiting directions of PQ and PR are said to be conjugate directions at P. Thus, the characteristic of the tangent plane, as the point of contact moves along a given curve, is the tangent line in the direction conjugate to that of the curve at a point of contact.

At a point $P \ 2 \ S$, let two directions $(du^1; du^2)$ and $(\ u^1; \ u^2)$ satisfy the relation

$$b_{11}du^1 \ u^1 + b_{12} \ du^1 \ u^2 + du^2 \ u^1 \ + b_{22}du^2 \ u^2 = 0;$$

or

$$b \ \ du \ \ u \ = 0; \tag{8.37}$$

then these are called conjugate directions at P. Thus, the necessary and sufficient condition that the direction $\frac{u^1}{u^2}$ be conjugate to the direction $\frac{du^1}{du^2}$ is

$$b_{11}\frac{du^1}{du^2} \ \frac{u^1}{u^2} + b_{12} \ \frac{du^1}{du^2} + \frac{u^1}{u^2} \ + b_{22} = 0 \tag{8.38}$$

and the symmetry of the relation shows that the property is a reciprocal one. Moreover, Eq. (8.38) is linear in each of the ratios $du^1 : du^2$ and $\delta u^1 : \delta u^2$; so that to a given direction there is one and only one conjugate direction.

EXAMPLE 8.3.10 Find a necessary condition so that the two directions determined by $p_{\alpha\beta}\, du^\alpha du^\beta = 0;\ p_{\alpha\beta} = p_{\beta\alpha}$ are conjugate.

Solution: Given that, $p_{\alpha\beta}\, du^\alpha du^\beta = 0$; i.e.

$$p_{11}(du^1)^2 + 2\,p_{12}du^1du^2 + p_{22}(du^2)^2 = 0.$$

Let $(du^1; du^2)$ and $(\delta u^1; \delta u^2)$ be the solutions, then

$$\frac{du^1}{du^2} + \frac{\delta u^1}{\delta u^2} = -2\frac{p_{12}}{p_{11}} \text{ and } \frac{du^1}{du^2}.\frac{\delta u^1}{\delta u^2} = \frac{p_{22}}{p_{11}}.$$

From Eq. (8.37), we get

$$b_{11}\frac{p_{22}}{p_{11}} + b_{12}\left(-2\frac{p_{12}}{p_{11}}\right) + b_{22} = 0$$

or

$$b_{11}p_{22} - 2b_{12}p_{12} + b_{22}p_{11} = 0$$

or

$$b^{\alpha\beta}p_{\alpha\beta} = 0;$$

where $b^{\alpha\beta}$ are given by

$$b^{\alpha\beta} = \frac{\text{cofactor of } b_{\alpha\beta} \text{ in } |b_{\alpha\beta}|}{|b_{\alpha\beta}|}.$$

Theorem 8.3.3 Parametric curves have conjugate directions if and only if $b_{12} = 0$.

Proof: Curve conjugate to u^1 curve is given by Eq. (8.37) as

$$b_{11}du^1\,\delta u^1 + b_{12}du^1\,\delta u^2 = 0; \text{ as } du^2 = 0.$$

Since the conjugate of u^1 curve is the u^2 curve, $\delta u^1 = 0$ but $\delta u^2 \neq 0$. Therefore, $b_{12} = 0$ which is the necessary condition.

Conversely, if $b_{12} = 0$; then the curve conjugate of u^1 curve is given by

$$b_{11}\,\delta u^1 = 0 \Rightarrow \delta u^1 = 0;$$

which shows that it is the u^2 curve. Hence, the principal directions at a point of the surface are conjugate directions. Thus the null lines on a minimal surface form a conjugate system.

Deduction 8.3.4 Let the lines of curvature be taken as parametric curves, so that $a_{12} = 0$ and $b_{12} = 0$. The directions $\frac{du^1}{du^2}$ and $\frac{\delta u^1}{\delta u^2}$ are inclined to the curve u^2 = constant at angles θ, θ', such that

$$\tan\theta = \sqrt{\frac{a_{22}}{a_{11}}}\frac{du^1}{du^2}; \quad \tan\theta' = \sqrt{\frac{a_{22}}{a_{11}}}\frac{\delta u^1}{\delta u^2}.$$

The condition that two directions be conjugate may be expressed

$$b_{11}\frac{du^1}{du^2}\frac{\delta u^1}{\delta u^2} + b_{12}\left(\frac{du^1}{du^2} + \frac{\delta u^1}{\delta u^2}\right) + b_{22} = 0$$

or

$$\tan\theta\tan\theta' = -\frac{b_{11}}{a_{11}}\frac{a_{22}}{b_{22}} = -\frac{\kappa_1}{\kappa_2}; \text{ as } b_{12} = 0;$$

that is to say, provided they are parallel to conjugate diameters of the indicatrix.

EXAMPLE 8.3.11 Show that the parametric curves are conjugate on the surface of revolution

$$x^1 = u^1\cos u^2; \; x^2 = u^1\sin u^2; \; x^3 = f(u^1)$$

with $f(u^1)$ of class C^2.

Solution: The parametric representation of the right helicoid is given by

$$x^1 = u^1\cos u^2; \; x^2 = u^1\sin u^2; \; x^3 = f(u^1)$$

i.e.

$$\mathbf{r} = (x^1; x^2; x^3) = \left(u^1\cos u^2; u^1\sin u^2; f(u^1)\right).$$

The symmetric covariant tensors $b_{\alpha\beta}$ for the second fundamental form are given by

$$b_{11} = \frac{f_{11}}{\sqrt{1+f_1^2}}; \; b_{22} = \frac{u^1 f_1}{\sqrt{1+f_1^2}} \text{ and } b_{12} = 0 = b_{21}.$$

where $f_1 = \frac{\partial f}{\partial u^1}$ and $f_{11} = \frac{\partial^2 f}{\partial u^1 \partial u^1}$. Since $b_{12} = 0$, the parametric curves on the given surface are conjugate.

8.3.3 Asymptotic Directions

The asymptotic directions at a point on the surface are the self-conjugate directions; and the asymptotic line is a curve whose direction at every point is self-conjugate.

Consequently, in Eq. (8.38) connecting conjugate directions we put $\frac{u^1}{u^2}$ equal to $\frac{du^1}{du^2}$, the directions on the surface given by

$$b_{11}(du^1)^2 + 2\,b_{12}du^1du^2 + b_{22}(du^2)^2 = 0$$

or

$$b \quad du \; du \;\; = b \qquad\quad = 0 \tag{8.39}$$

and are called the asymptotic directions. The curves whose tangents are asymptotic directions are called an asymptotic line. Thus, there are two asymptotic directions at a point. The asymptotic directions are

(i) real and distinct, when $b_{12}^2 \quad b_{11}b_{22}$ is positive, i.e. $\; < \; 0$;

(ii) imaginary, when $\; > \; 0$;

(iii) identical, when $\; = 0:$

Now, the normal curvature $_{(n)}$ is given in Eq. (8.14). In the case (iii) the surface is a developable, and the single asymptotic line through a point is a generator. Since for an asymptote direction Eq. (8.39) holds, it follows that, for an asymptotic direction the normal curvature is zero, i.e.

$$_{(n)} = 0 \;) \quad b \quad du \;\, du \;\; = 0$$

for the asymptotic directions. These directions are, therefore, the directions of the asymptotes of the indicatrix. They are at right angles when the indicatrix is a rectangular hyperbola, i.e. when the principal curvature are equal and opposite. Thus, the asymptotic lines are orthogonal when the surface is a minimal surface. The osculating plane at any point of an asymptotic line is the tangent plane to the surface.

Deduction 8.3.5 Let $(du^1; du^2)$ be the direction of asymptotic line at P then we know

$$b \quad du \;\, du \;\; = b_{11}(du^1)^2 + 2\,b_{12}du^1du^2 + b_{22}(du^2)^2 = 0:$$

Now, the normal curvature $_{(n)}$ is given by

$$_{(n)} = \frac{b_{11}(du^1)^2 + 2\,b_{12}du^1du^2 + b_{22}(du^2)^2}{a_{11}(du^1)^2 + 2\,a_{12}du^1du^2 + a_{22}(du^2)^2} = 0:$$

If $_a$ and $_b$ are principal curvatures at P, then, by Euler's theorem

$$_a\cos^2 \quad + \quad _b\sin^2 \quad = \quad _{(n)} = 0: \tag{8.40}$$

Now, if be the normal curvature in a direction perpendicular to asymptotic line then from Eq. (8.40), we get

$$= {}_a \cos^2 \frac{}{2} + \quad + {}_b \sin^2 \frac{}{2} +$$

or

$$= {}_a \sin^2 + {}_b \cos^2 : \tag{8.41}$$

Adding Eqs. (8.40) and (8.41), we get

$$= {}_a + {}_b = 2 \frac{a + b}{2}$$

$$= \text{twice of mean normal curvature at } P:$$

Thus, the normal curvature in a direction perpendicular to an asymptotic line is twice the mean normal curvature.

EXAMPLE 8.3.12 Show that a straight line on a surface is an asymptotic line.

Solution: We know, the normal curvature $_{(n)}$ is given by

$$_{(n)} = \cos ;$$

where is the curvature of the curve on the surface and is the angle between the principal normal and the surface normal. Since for a straight line $= 0$; so,

$$_{(n)} = \frac{b \quad du \ du}{a \quad du \ du} = 0$$

$$) \quad b \quad du \ du = b \qquad = 0:$$

Hence, any straight line on a surface is an asymptotic line. From this result, it follows that at each point of an asymptotic curve C, at which > 0, the principal normal of C lies in the tangent plane of the surface. Thus the generating straight lines of a cylinder or as cone are asymptotic curves on the surface. From this we obtain the following important property of asymptotic curves.

At any point of an asymptotic curve C for which the curvature > 0, the binormal of C and the normal to the surface coincide. Consequently, at any point of C, the osculating plane of C and the tangent plane to the surface then coincide.

Theorem 8.3.4 The parametric curves are asymptotic lines if and only if

$$b_{11} = b_{22} = 0:$$

Proof: First, let the parametric curves u^1 = constant and u^2 = constant be asymptotic lines. Then from Eq. (8.39), we get

$$b \quad du \quad du \;=\; b \qquad\quad = 0:$$

For u^1 curve, i.e. $du^2 = 0$; this equation reduces to

$$b \quad {}_{(1)}\;{}_{(1)} = b \quad \frac{1}{\sqrt{a_{11}}}\;{}_{(1)}\;\frac{1}{\sqrt{a_{11}}}\;{}_{(1)} = 0$$

$$\Rightarrow \frac{b_{11}}{a_{11}} = 0 \Rightarrow b_{11} = 0:$$

Similarly, for u^2 curve, i.e. $du^1 = 0$; i.e.

$$b \quad {}_{(2)}\;{}_{(2)} = b \quad \frac{1}{\sqrt{a_{22}}}\;{}_{(2)}\;\frac{1}{\sqrt{a_{22}}}\;{}_{(2)} = 0$$

$$\Rightarrow \frac{b_{22}}{a_{22}} = 0 \Rightarrow b_{22} = 0:$$

Conversely, let $b_{11} = b_{22} = 0$; then the differential Eq. (8.39) determining the asymptotic lines is

$$b_{12}du^1du^2 = 0 \Rightarrow du^1du^2 = 0; \quad \text{as } b_{12} \neq 0;$$

i.e. the curves are parametric. Of course, co-ordinates of this type can be introduced on a surface S if and only if at any point of S there are two (different real) asymptotic directions.

EXAMPLE 8.3.13 Prove that the parametric curves on a surface are asymptotic lines if and only if $b_{11} = b_{22} = 0$ and show that

$$= \quad \frac{b_{12}^2}{a}; \quad H = \quad \frac{a_{12}b_{12}}{a}; \quad \frac{a_{12}}{b_{12}} = \frac{H}{\ }:$$

Solution: We know, parametric curves are asymptotic lines if and only if $b_{11} = b_{22} = 0$: Now, the Gaussian curvature is given by

$$= \frac{b}{a} = \frac{b_{11}b_{22} \quad b_{12}^2}{a_{11}a_{22} \quad a_{12}^2} = \frac{b_{12}^2}{a_{11}a_{22} \quad a_{12}^2} = \quad \frac{b_{12}^2}{a}:$$

Since $b_{11} = b_{22} = 0$, therefore, the mean curvature H is given by

$$H = \frac{1}{2}a \quad b \quad = \frac{1}{2} \; a^{11}b_{11} + a^{22}b_{22} + 2\,a^{12}b_{12}$$

$$= a^{12}b_{12} = \quad \frac{a_{12}b_{12}}{a}:$$

These are the values of the mean curvature H and the Gaussian curvature , when parametric curves are asymptotic lines. Thus, the ratio is given by

$$\frac{H}{} = \frac{a_{12}b_{12}}{a} \quad \frac{a}{b_{12}^2} = \frac{a_{12}}{b_{12}}:$$

EXAMPLE 8.3.14 Show that the parametric curves are asymptotic lines to the surfaces

$$x^1 = u^1 \cos u^2;\ x^2 = u^1 \sin u^2;\ x^3 = cu^2:$$

Prove that the asymptotic lines consist of generators and the curves of intersection with coaxial right circular cylinders.

Solution: The parametric curves are asymptotic lines if $b_{11} = 0$; $b_{22} = 0$ and $b_{12} \neq 0$: For the given surface

$$x^1 = u^1 \cos u^2;\ x^2 = u^1 \sin u^2;\ x^3 = cu^2$$

or

$$r = (x^1; x^2; x^3) = \quad u^1 \cos u^2; u^1 \sin u^2; cu^2$$

the symmetric covariant tensors b for the second fundamental form are given by

$$b_{11} = 0; b_{22} = 0 \text{ and } b_{12} = \quad \frac{c}{\sqrt{c^2 + (u^1)^2}} \neq 0:$$

The differential equation giving the asymptotic lines is

$$b \quad du \ du \ = b_{11}(du^1)^2 + 2b_{12}du^1du^2 + b_{22}(du^2)^2 = 0$$

or

$$\frac{c}{\sqrt{c^2 + (u^1)^2}} du^1du^2 = 0$$

or

$$u^1 = \text{constant and } u^2 = \text{constant};$$

i.e. the parametric curves. Now, the curves u^2 = constant are generators, whereas the curves u^1 = constant are the curves of intersection of the given helicoid with the circular cylinders $(x^1)^2 + (x^2)^2 = (u^1)^2$: The axis of these coaxial cylinders is x^3 axis which is also the axis of the given helicoid.

EXAMPLE 8.3.15 Determine the asymptotic curves of a cylinder of revolution.

Solution: Let the parametric equation of the surface S is of the form

$$r = (x^1; x^2; x^3) = (a \cos u^1; a \sin u^1; u^2):$$

We know any straight line on a surface S of class r 2 is an asymptotic curve. Thus the generating straight lines of a cylinder (or a cone) S are asymptotic curves on these surfaces. We will prove that those curves are the only asymptotic curves of S. The second fundamental magnitudes are given by

$$b_{12} = b_{22} = 0 \text{ and } b_{11} = \ 1 \ 6= 0$$

Thus Eq. (8.39) takes the form

$$b_{11}(du^1)^2 + b_{22}(du^2)^2 + 2b_{12}du^1du^2 = 0$$
$$)\quad b_{11}(du^1)^2 = 0; \text{ where } b_{11} = \ 1 \ 6= 0$$
$$)\quad du^1 = 0; \text{ that is, } u^1 = \text{constant.}$$

Since this is the only solution of that equation the above straight lines are the only asymptotic curves on the cylinder.

EXAMPLE 8.3.16 Show that the two directions given by $h \ du \ du = 0$; are orthogonal if and only if $a \ h = 0$:

Solution: The given equation $h \ du \ du = 0$ can be written in the form

$$h_{11}(du^1)^2 + h_{12}du^1du^2 + h_{21}du^2du^1 + h_{22}(du^2)^2 = 0$$

or

$$h_{11}\ \frac{du^1}{du^2}^{\ 2} + (h_{12} + h_{21})\frac{du^1}{du^2} + h_{22} = 0:$$

Let $\frac{du^1}{du^2}$ and $\frac{u^1}{u^2}$ be the roots of the quadratic equation. Then

$$\frac{du^1}{du^2} + \frac{u^1}{u^2} = \frac{h_{12} + h_{21}}{h_{11}} \text{ and } \frac{du^1}{du^2}\frac{u^1}{u^2} = \frac{h_{22}}{h_{11}}:$$

The two directions $(du^1; du^2)$ and $(u^1; u^2)$ will be perpendicular if and only if

$$a_{11}du^1 u^1 + a_{12}du^1 u^2 + a_{21}du^2 u^1 + a_{22}du^2 u^2 = 0$$

or

$$a_{11}\frac{du^1}{du^2}\frac{u^1}{u^2} + a_{12}\ \frac{du^1}{du^2} + \frac{u^1}{u^2}\ + a_{22} = 0$$

or

$$a_{11}\frac{h_{22}}{h_{11}} \quad a_{12} \quad \frac{h_{12} + h_{21}}{h_{11}} \quad + a_{22} = 0$$

or

$$a_{11}h_{22} \quad a_{12}(h_{12} + h_{21}) + a_{22}h_{11} = 0$$

or

$$a \; a^{22}h_{22} + a^{12}h_{12} + a^{21}h_{21} + a^{11}h_{11} \; = 0$$

or

$$a \quad h \quad = 0; \quad \text{as } a \neq 0 :$$

EXAMPLE 8.3.17 The asymptotic lines are at right angles if and only if $H = 0$:

Solution: The asymptotic lines are given by the equation

$$b \quad du \; du \; = b \qquad = 0 :$$

Thus, the asymptotic lines are at right angles if and only if

$$a \quad b \quad = 0 \;) \quad H = \frac{1}{2}a \quad b \quad = 0 ;$$

where H is the mean curvature. Thus, the asymptotic lines are right angles if and only if the surface is a minimal surface. Hence the asymptotic lines form an orthogonal system, bisecting the angles between the lines of curvature.

EXAMPLE 8.3.18 Show that on a sphere there is no real asymptotic line.

Solution: The parametric representation of the sphere of radius a is given by

$$x^1 = a \sin u^1 \cos u^2; \quad x^2 = a \sin u^1 \sin u^2; x^3 = a \cos u^2$$

or

$$r = (x^1; x^2; x^3) = \quad a \sin u^1 \cos u^2; a \sin u^1 \sin u^2; a \cos u^2 \; :$$

For the given surface, the symmetric covariant second order tensor a for the first fundamental form are given by

$$a_{11} = a^2; \quad a_{22} = a^2 \sin^2 u^1; \quad a_{12} = 0 = a_{21}$$

and the symmetric covariant second order tensors b for the second fundamental form are given by

$$b_{11} = \quad a; \quad b_{22} = \quad a \sin^2 u^1; \quad b_{12} = 0 = b_{21}:$$

Since $a_{12} = 0 = b_{12}$, this given parametric curve has the line of curvature. In fact,

$$\frac{b_{11}}{a_{11}} = \frac{b_{12}}{a_{12}} = \frac{b_{22}}{a_{22}} = \quad \frac{1}{a};$$

i.e. b are proportional to a : Now, the asymptotic lines are given by

$$b \quad du \quad du \ = b_{11}(du^1)^2 + 2b_{12}du^1du^2 + b_{22}(du^2)^2 = 0$$

or

$$a(du^1)^2 \quad a\sin^2 u^1(du^2)^2 = 0$$

or

$$(du^1)^2 + \sin^2 u^1(du^2)^2 = 0:$$

Hence, there is no real asymptote.

Theorem 8.3.5 The torsion of an asymptotic line equals to p —; where is the Gaussian curvature of the surface.

Proof: From Eq. (8.6), we have, for an asymptotic curve,

$$^i = b \qquad ^i + \ _g\ ^i; = \ _g\ ^i; \quad \text{as}\, b \qquad = 0; \qquad (8.42)$$

where ^{i} is the principal normal and ^{i} is the space vector giving the same direction on the surface as ^{i}; the unit normal to the surface S. Therefore,

$$(\quad ^i)(\quad ^i) = (\ _g\ ^i)(\ _g\ ^i)$$

or

$$^2 = \ ^2_h\ ) \qquad = \qquad _h \qquad (8.43)$$

from which we conclude that the curvature and the geodesic curvature of an asymptotic line are equal in magnitude. Also,

$$^i = \ _g\ ^i\ ) \quad ^i = \quad ^i: \qquad (8.44)$$

We now derive the well known formula for torsion of an asymptotic line. From Eq. (8.44), it follows that the principal normal ^{i} of an asymptotic line is tangent to the surface and hence the binormal of an asymptotic line coincides with the surface normal ^{i}, i.e.

$$^i = \quad ^i: \qquad (8.45)$$

Taking intrinsic derivative of both the sides of Eq. (8.45), we get

$$\frac{\ \ ^{i}}{s} = \frac{\ \ ^{i}}{s} \Rightarrow \quad ^{i} = \ ^{i}_{;} \frac{du}{ds} = \ ^{i}_{;} \quad :$$

Therefore,

$$^{2} = g_{ij} (\quad ^{i})(\quad ^{j}) = g_{ij} \ ^{i}_{;} \ ^{j}_{;}$$

$$= c \qquad ; \quad \text{as}\, c \quad = g_{ij} \ ^{i}_{;} \ ^{j}_{;} :$$

Using the relation

$$c \qquad 2Hb \quad + \ a \qquad = 0;$$

where H is the mean curvature and is the Gaussian curvature, we get

$$c \qquad\qquad 2Hb \qquad\qquad + \ a \qquad\qquad = 0$$

or

$$^{2} \quad 0 + \ ^{2} = 0 \Rightarrow \quad = \sqrt{\quad} :$$

Therefore, the torsions of the two asymptotic lines through a point are equal in magnitude and opposite in sign; and the square of either is negative of the specific/Gaussian curvature of the surface. This theorem is formulated by Beltrami Enneper.

EXAMPLE 8.3.19 Find the asymptotic lines on the surface of revolution

$$x^1 = u^1 \cos u^2; \quad x^2 = u^1 \sin u^2; x^3 = f(u^1):$$

Find also the values of their torsions.

Solution: For the given surface

$$x^1 = u^1 \cos u^2; \; x^2 = u^1 \sin u^2; x^3 = f(u^1)$$

or

$$r = (x^1; x^2; x^3) = \quad u^1 \cos u^2; \; u^1 \sin u^2; f(u^1)$$

the symmetric covariant tensors b for the second fundamental form are given by

$$b_{11} = \frac{u^1 f_{11}}{\sqrt{1+f_1^2}}; b_{12} = 0 = b_{21} \text{ and } b_{22} = \frac{(u^1)^2 f_1}{\sqrt{1+f_1^2}}:$$

The differential equation giving the asymptotic lines is

$$b_{11}(du^1)^2 + 2b_{12}du^1du^2 + b_{22}(du^2)^2 = 0$$

or

$$f_{11}(du^1)^2 + u^1 f_1 (du^2)^2 = 0:$$

Using Beltrami Enneper's formula the torsion of an asymptotic line equals to $\sqrt{\ }$; where is the Gaussian curvature of the surface, as

$$= \sqrt{\ } = \frac{\sqrt{(u^1)^3 f_{11} f_1}}{(u^1)^2(1+f_1^2)}:$$

8.4 Conformal Mapping

Isometric mappings of a surface S on another surface S have been already mentioned. It is often convenient to consider mappings which are more general than isometrices-for example, it is useful to map parts of the earth's surface onto a flat atlas. Certain of these maps are particular cases of conformal mappings.

A surface S is said to be conformally mapped on a surface S if there is a differentiable homomorphism of S on S such that the angle between any two curves at an arbitrary point P on S is equal to the angle between the corresponding curves on S .

An isometric mappings preserves both distances and angles, whereas a conformal mapping just preserves angles. Let the fundamental forms of S, S be respectively

$$ds^2 = a_{11}du^2 + 2a_{12}dudv + a_{22}dv^2$$

$$ds^{2} = a_{11}du^2 + 2a_{12}dudv + a_{12}^{2}dv^2$$

the correspondence being such that corresponding points P; P have the same parametric values. Then if $\frac{ds}{ds}$ has the same value for all directions at the given point, we must have

$$\frac{a_{11}}{a_{11}} = \frac{a_{12}}{a_{12}} = \frac{a_{22}}{a_{22}} = \frac{ds^{2}}{ds^2} = {}^{2}; \qquad (8.46)$$

where is function of u and v or a constant. Equation (8.46) is evidently a necessary and sufficient condition for a differentiable homomorphism to be conformal. Therefore

$$ds = ds:$$

The quantity may be called the linear magnification. When = 1, for all points of the surface, ds = ds. The conformal representation is then said to be isometric, and the surfaces are said to be applicable. In this case, corresponding elements of the two surfaces are congruent. Thus every isometric mapping is conformal.

EXAMPLE 8.4.1 Prove that every point on a surface has a neighbourhood which can be mapped conformably on some neighbourhood of any other surface.

Solution: Let S be the given surface with metric

$$ds^2 = a_{11}du^2 + 2\,a_{12}dudv + a_{22}dv^2$$

in some co-ordinate domain. At any point P there are two (imaginary) directions such that $ds^2 = 0$. These are called isotropic directions at P, and since $a = a_{11}a_{22} \quad a_{12}^2 \neq 0$ if follows that these directions are always distinct.

When curves along these directions are chosen as parametric curves the metric assumes the form $ds^2 = \quad dudv$. The change of parameters

$$u = U + iV; v = U \quad iV;$$

where U and V are real, leads to a metric of the form

$$ds^2 = \quad {}^2[dU^2 + dV^2]:$$

If this is compared with the metric of the plane

$$ds^2 = du^{\,2} + dv^{\,2};$$

it is rapidly seen that the mapping $u = U; v = V$ gives a conformal mapping of a region of the given surface on a region of the plane. Hence the result follows.

EXAMPLE 8.4.2 Show that null lines on a surface correspond to null lines in the conformal representation.

Solution: We have deduce that $ds^{\,2} = r^2 ds^2$, if ds^2 vanishes along a curve S; $ds^{\,2}$ will vanish along the corresponding curve on S . Conversely, let the null lines be taken as parametric curves. Then

$$a_{11} = a_{22} = 0 \text{ and } a_{11} = a_{22} = 0$$

$$) \quad \frac{ds^{\,2}}{ds^2} = \frac{2a_{12}dudv}{2a_{12}dudv} = \frac{a_{12}}{a_{12}}:$$

Since the $\frac{ds}{ds}$ has the same value for all arcs through a given point, the representation is conformal. Thus, if null lines on S corresponds to null lines on S , the representation is conformal.

8.5 Spherical Image

We shall now consider briefly the spherical representation of a surface, in which each point or configuration on the surface has its representation on a unit sphere, whose centre may be taken as origin. If is the unit normal at the point P on the surface S, the point Q whose position vector is is said to correspond to P, or the image of P. Clearly, Q lies on the unit sphere; and if P moves in any curve on the surface, Q moves in the corresponding curve on the sphere. The mapping thus defined is called the Gaussian spherical mapping of the surface S. The set of all image points is called the spherical image of S. Since the position vector $\bar{r}$ of Q is given by $\bar{r} =$, it follows that

$$\frac{\partial}{\partial u} = \frac{\partial :}{\partial u} = \frac{1}{a^2}\,(a_{12}b_{12} \quad a_{22}b_{11})\,\frac{\partial}{\partial v} + (\,a_{12}b_{11} \quad a_{11}b_{12})\,\frac{\partial}{\partial v}$$

$$\frac{\partial}{\partial v} = \frac{\partial}{\partial v} = \frac{1}{a^2}\,(a_{12}b_{22} \quad a_{22}b_{11})\,\frac{\partial}{\partial u} + (a_{12}b_{12} \quad a_{11}b_{12})\,\frac{\partial}{\partial v}\,:$$

Consequently, if $a_{11}; a_{12}; a_{22}$ denote the fundamental magnitudes of the first order for the spherical image

$$\left.\begin{aligned} a_{11} &= \frac{1}{a^2}\; a_{11}b_{12}^2 \quad 2a_{12}b_{11}b_{12} + a_{22}b_{11}\;; \\ a_{12} &= \frac{1}{a^2}\; a_{11}b_{12}b_{22} \quad a_{12}b_{12}^2 \quad a_{12}b_{11}b_{22} + a_{22}b_{11}b_{12}\;; \\ a_{22} &= \frac{1}{a^2}\; a_{11}b_{22}^2 \quad 2a_{12}b_{12}b_{22} + a_{22}b_{12}^2\;; \end{aligned}\right\} \tag{8.47}$$

or, in terms of the first and second curvatures

$$a_{11} = Hb_{11} \quad ka_{11};\;\; a_{12} = Hb_{12} \quad ka_{12};\;\; a_{22} = Hb_{22} \quad ka_{22} \tag{8.48}$$

In virtue of Eq. (8.48) we may write the square of the linear element of the image.

$$ds^2 = H(b_{11}du^2 + 2b_{12}dudv + b_{22}dv^2) \quad k(a_{11}du^2 + 2a_{12}dudv + a_{22}dv^2);$$

or, if $_{(n)}$ is the normal curvature of the given surface in the direction of the arc-length

$$ds^2 = \;\; _{(n)}H \quad k \;\; ds^2:$$

If then $_{(1)}$ and $_{(2)}$ are the principal curvatures of the surface, we may write this in virtue of Euler's theorem

$$\begin{aligned} ds^2 &= \Big[\; _{(1)} + \; _{(2)} \quad _{(1)}\cos^2 \; + \; _{(2)}\sin^2 \quad _{(1)} \; _{(2)} \Big]\, ds^2 \\ &= \; _{(1)}\cos^2 \; + \; ^2_{(2)}\sin^2 \;\; ds^2: \end{aligned} \tag{8.49}$$

It is clear from either of these formulae that the value of the quotient $\frac{ds}{ds}$ depends upon the direction of the arc element. The fundamental magnitudes for the spherical representation, as given by Eq. (8.48), become in the case of a minimal surface

$$a_{11} = \quad a_{11}; \; a_{12} = \quad a_{12}; \; a_{22} = \quad a_{22}: \qquad (8.50)$$

From these relations several interesting general properties may be deduced.

EXAMPLE 8.5.1 Show that the spherical image is not a conformal representation in general.

Solution: The spherical image be conformal, however, if $_{(1)} = \quad _{(2)}$. When $_{(1)} = \quad _{(2)}$ at all points, the Gaussian curvature becomes

$$H = \frac{1}{2} \quad _{(1)} + \quad _{(2)} = 0$$

i.e. H vanishes indentically and the surface is a minimal surface. Thus, for a minimal surface

$$ds^2 = \quad ds^2:$$

Thus $\frac{ds}{ds}$ is independent of the direction of the arc-element through the point, and the representation is conformal. The magnification has the value $p\overline{\quad}$, the second curvature being essentially negative for a real minimal surface. Thus, the spherical representation of a minimal surface is conformal. Therefore, in general, the spherical image is not a conformal representation.

Moreover it follows from Eq. (8.49) that the turning values of $\frac{ds}{ds}$ are given by cos = 0 and sin = 0. Thus the greatest and least values of the magnification at a point are numerically equal to the principal curvatures. From this it follows that if the spherical image of a surface is a conformal representation, either the surface is minimal, or else its principal curvatures are equal at each point.

EXAMPLE 8.5.2 Prove that null lines on a minimal surface become both null lines and asymptotic lines in the spherical representation.

Solution: Let the null lines be taken as parametric curves, then $a_{11} = 0 = a_{22}$. Therefore

$$Hb_{11} \quad a_{11} = 0 \quad \text{and} \quad Hb_{22} \quad a_{22} = 0:$$

Thus the parametric curves in the spherical image are null lines. Again considering the second order magnitudes for the sphere, we have

$$b_{11} = 0 = b_{12}$$

and therefore, the parametric curves in the spherical image are also asymptotic lines. Conversely, let the null lines are parametric curves, then $a_{11} = 0 = a_{22}$; and since the parametric curves are also null lines in the spherical image

$$Hb_{11} \quad ka_{11} = 0;\ Hb_{22} \quad ka_{22} = 0$$

$$)\ \ Hb_{11} = 0 \quad \text{and} \quad Hb_{22} = 0:$$

Consequently, either $H = 0$ and the surface is minimal, or else $b_{11} = 0 = b_{22}$. In the later case, it follows that

$$H = \frac{2b_{12}}{a_{12}} \quad \text{and} \quad k = \frac{b_{12}^2}{a_{12}^2} \quad) \quad H^2 \quad 4 = 0;$$

which is the condition that the principal curvatures should be equal. Thus, if the null lines in the spherical representation, either the surface is minimal, or else its principal curvatures are equal.

EXAMPLE 8.5.3 Show that the isometric lines on a minimal surface are also isometric in the spherical representation.

Solution: If the isometric lines are taken as parametric curves, we have

$$a_{12} = 0 \quad \text{and} \quad \frac{a_{11}}{a_{22}} = \frac{U(u)}{V(v)};$$

where U is a function of u only and V is a function of v only. Therefore, it follows that

$$\frac{H}{} = \frac{a_{12}}{b_{12}};\ \frac{a_{12}}{a_{22}} = \frac{U(u)}{V(v)};$$

showing that the parametric curves in the spherical image are also isomorphic. Hence the theorem. This result is obvious from the fact that the spherical image on a minimal surface is conformal.

In particular, the spherical image of the lines of curvature on a minimal surface are isometric curves, for the lines of curvature on a minimal surface have been shown to be isometric.

EXAMPLE 8.5.4 Show that the lines of curvature on a surface are orthogonal in their spherical representation.

Solution: The lines of curvature on a surface are orthogonal in their spherical representation. For if they are taken as parametric curves, we have $a_{12} = 0 = b_{12}$, hence $a_{12} = 0$ which proves the statement. Further if $a_{12} = 0$ and $a_{12} = 0$ we must also have $b_{12} = 0$ unless the Gaussian curvature H vanishes identically. Thus, if the surface is not a minimal surface, the lines of curvature are the only orthogonal system whose spherical image is orthogonal.

Moreover, by Rodrigue’s formula along a line of curvature dr is parallel to d and therefore also to $d\bar{r}$. Hence the tangent to a line of curvature is parallel to the tangent to its spherical image at the corresponding point.

Conversely if dr is parallel to dr it is parallel to d . The vectors ; + d , dr are therefore coplanar, and the line is a line of curvature. Thus if the relation holds for a curve on a surface it must be a line of curvature.

EXAMPLE 8.5.5 Prove that if two directions are conjugate at a point on a given surface, each is perpendicular to the spherical image of the other at the corresponding point.

Solution: If dr and ds be two infinitesimal displacements on a given surface, and d the change in the unit normal due to the former, the directions of the displacements will be conjugate provided

$$d \quad ds = 0:$$

Conversely this relation holds if the directions are conjugate. But $d = dr$, where dr is the spherical image of dr. Consequently

$$dr \quad ds = 0:$$

Thus if two directions are conjugate at a point on a given surface, each is perpendicular to the spherical image of the other at the corresponding point. It follows that the inclination of two conjugate directions are equal, or supplementary, to that of their spherical representations.

Further, an asymptotic line is self-conjugate. Hence an asymptotic line on a surface is perpendicular to its spherical image at the corresponding point.

8.6 Surface of Revolution

A surface of revolution may be generated by the rotation of a plane curve about an axis in its plane. Let C: $x^3 = f(x^1)$ be a curve drawn on the plane $x^2 = 0$; where x^i are Cartesian co-ordinates of a point. Let $P(x^1; 0; x^3)$ be a point on the curve, then P traces a circle as the curve C is rotated about the x^3 axis. The surface generated by the curve is called the surface of revolution and its implicit equation is

$$x^3 = \sqrt{(x^1)^2 + (x^2)^2} : \qquad (8.51)$$

To obtain the parametric equation of the surface, let the generating curve be given by

$$x^1 = f_1(u^1); \quad x^2 = 0; \quad x^3 = f_2(u^2):$$

Let u^2 be the angle of rotation about the x^3 axis measured from the x^1 axis, then

$$x^1 = f_1(u^1)\cos u^2;\, x^2 = f_1(u^1)\sin u^2;\ \ x^3 = f_2(u^1).$$

This is the parametric representation of the surface of revolution obtained by rotating a curve about the x^3 axis. The curve C is called the generator of the curve.

Let the axis of rotation be x^3 and u^1 denote perpendicular distance from it, the co-ordinates of a point on the surface may be expressed

$$x^1 = u^1\cos u^2;\, x^2 = u^1\sin u^2;\ \ x^3 = f(u^1);$$

the longitude u^2 being the inclination of the axial plane through the given point to the x^3x^1 plane. The parametric curves u^2 = constant are the meridian lines, or intersections of the surface by the axial planes; the curves u^1 = constant are the parallels, or intersection of the surface by planes perpendicular to the axis.

EXAMPLE 8.6.1 Let S is a surface of revolution

$$x^1 = u^1\cos u^2;\, x^2 = u^1\sin u^2;\ \ x^3 = f(u^1);\ \ f(u^1) \in C^2.$$

(a) Find the surface of revolution that has a minimal surface.

(b) Find the surface of revolution that has a constant negative Gaussian curvature.

(c) Find the complete integral of the equations of geodesics.

Solution: With $u^1; u^2$ as parameters, the parametric representation of the right helicoid is given by

$$x^1 = u^1\cos u^2;\, x^2 = u^1\sin u^2;\ \ x^3 = f(u^1)$$

i.e.

$$\mathbf{r} = (x^1; x^2; x^3) = \left(u^1\cos u^2; u^1\sin u^2; f(u^1)\right).$$

Here we have to show that the catenoid is the only minimal surface of revolution. The first order magnitudes are given by

$$a_{11} = 1 + f_1^2;\ a_{22} = (u^1)^2 \text{ and } a_{12} = 0 = a_{21};$$

$$\Rightarrow\ a = |a_{\alpha\beta}| = \begin{vmatrix} 1 + f_1^2 & 0 \\ 0 & (u^1)^2 \end{vmatrix} = (u^1)^2(1 + f_1^2);$$

where $f_1 = \frac{\partial f}{\partial u^1}$. Since $a_{12} = 0$, it follows that the parallels cut the meridians orthogonally. The second order magnitudes are given by

$$b_{11} = \frac{f_{11}}{\sqrt{1 + f_1^2}};\, b_{22} = \frac{u^1 f_1}{\sqrt{1 + f_1^2}} \text{ and } b_{12} = 0 = b_{21};$$

$$\Rightarrow\ b = |b_{\alpha\beta}| = \begin{vmatrix} \frac{f_{11}}{\sqrt{1 + f_1^2}} & 0 \\ 0 & \frac{u^1 f_1}{\sqrt{1 + f_1^2}} \end{vmatrix} = \frac{u^1 f_1 f_{11}}{1 + f_1^2};$$

where $f_1 = \frac{\partial f}{\partial u^1}$ and $f_{11} = \frac{\partial^2 f}{\partial u^1 \partial u^1}$. Since $a_{12} = 0$ and $b_{12} = 0$, the parametric curves are the lines of curvature. The equation for the principal curvatures reduces to

$$u^1(1 + f_1^2)^2 \kappa^2 - \sqrt{1 + f_1^2}\,\{u^1 f_{11} + f_1(1 + f_1^2)\}\kappa + f_1 f_{11} = 0.$$

This is a quadratic equation in κ which gives the two values $\kappa_{(1)}$ and $\kappa_{(2)}$ given by

$$\kappa_{(1)} = \frac{f_{11}}{(1 + f_1^2)^{3/2}}; \quad \kappa_{(2)} = \frac{f_1}{u^1 \sqrt{1 + f_1^2}}.$$

The first of those is the curvature of the generating curve. The second is the reciprocal of the length of the normal intercepted between the curve and the axis of rotation.

(a) Now, the mean curvature H is given by

$$H = \frac{a_{11}b_{22} - 2a_{12}b_{12} + a_{22}b_{11}}{a} = \frac{f_1(1 + f_1^2) + u^1 f_{11}}{u^1(1 + f_1^2)^{3/2}}.$$

The surface will be a minimal surface if $H = 0$; i.e. if

$$f_1(1 + f_1^2) + u^1 f_{11} = 0$$

or

$$F(1 + F^2) + u^1 F_1 = 0; \quad F = f_1 = \frac{\partial f}{\partial u^1}$$

or

$$\frac{du^1}{u^1} + \frac{dF}{F(1 + F^2)} = 0$$

or

$$\log u^1 + \log F - \frac{1}{2}\log(1 + F^2) = \log c; \text{ integrating}$$

or

$$\frac{u^1 F}{\sqrt{1 + f_1^2}} = c \Rightarrow F = \frac{\partial f}{\partial u^1} = \pm\frac{c}{\sqrt{(u^1)^2 - c^2}}.$$

Take the positive sign (the other case is exactly similar) and integrating we get

$$f + c_1 = \cosh^{-1}\left(\frac{u^1}{c}\right) \Rightarrow u^1 = c\cosh(x^3 + c_1).$$

Hence, the required surface is the surface of revolution obtained by revolving the catenary $u^1 = c\cosh(x^3 + c_1)$ about x^3 axis. Thus the only minimal surface of revolution is that formed by the revolution of a catenary about its directrix.

(b) Now, the Gaussian curvature K is given by

$$K = \frac{b}{a} = \frac{f_1 f_{11}}{(u^1)^2(1 + f_1^2)}.$$

Given that, the surface of revolution that has a constant negative Gaussian curvature, say $K = -\frac{1}{c^2}$. Therefore,

$$\frac{f_1 f_{11}}{(u^1)^2(1+f_1^2)} = -\frac{1}{c^2}$$

or

$$\frac{dF}{F^2} = -\frac{2u^1du^1}{c^2};\quad F = 1+f_1^2 = 1+\left(\frac{\partial f}{\partial u^1}\right)^2$$

or

$$\frac{1}{F} = \frac{1}{1+f_1^2} = \frac{(u^1)^2}{c^2};\quad \text{integrating}$$

or

$$1+f_1^2 = \frac{c^2}{(u^1)^2} \Rightarrow f_1 = \pm\frac{\sqrt{c^2-(u^1)^2}}{u^1};$$

where we choose the constant of integration equal to 0. Take the positive sign (the other case is exactly similar) and integrating we get

$$f = x^3 = \sqrt{c^2-(u^1)^2} + \frac{c}{2}\log\frac{c-\sqrt{c^2-(u^1)^2}}{c+\sqrt{c^2-(u^1)^2}}.$$

Hence, the required surface is the surface of revolution obtained by revolving the tractrix

$$x^3 = \sqrt{c^2-(u^1)^2} + \frac{c}{2}\log\frac{c-\sqrt{c^2-(u^1)^2}}{c+\sqrt{c^2-(u^1)^2}}.$$

about x^3 axis, which is the axis of tractrix.

(c) The second equation for geodesics is of the form

$$\frac{d^2u^2}{ds^2} + \frac{2}{u^1}\frac{du^1}{ds}\frac{du^2}{ds} = 0.$$

On multiplication by u^2 this equation becomes exact, and has for its integral

$$(u^1)^2\frac{du^2}{ds} = h;\quad h = \text{constant}.$$

If ψ is the angle at which the geodesics cuts the meridian, we may write $u^1\sin\psi = h$, a theorem due to Clairant. This is a first integral of the equation of geodesics, involving one orbitrary constant h.

To obtain the complete integral we observe that, for any arc on the surface,

$$ds^2 = (1+f_1^2)(du^1)^2 + (u^1)^2(du^2)^2$$

and therefore, for the arc of a geodesic

$$(u^1)^4(du^2)^2 = h^2(1+f_1^2)(du^1)^2 + h^2(u^1)^2(du^2)^2$$

or

$$du^2 = \frac{h}{u^1}\sqrt{\frac{1+f_1^2}{(u^1)^2-h^2}}\,du^1$$

or

$$u^2 = c \pm h\int \frac{1}{u}\sqrt{\frac{1+f_1^2}{(u^1)^2-h^2}}\,du^1$$

involving the two arbitrary constants c and h, is the complete integral of the equation of geodesics on a surface of revolution.

8.7 Exercises

1. Find the principal curvatures of the surface S defined by
$$x^1 = u^1;\ x^2 = u^2;\quad x^3 = f(u^1;u^2).$$
2. Show that the principal curvatures are $-1;\ -1$ for the surface
$$(x^1)^2 + (x^2)^2 + (x^3)^2 = 1.$$
3. Find the equation for the principal curvatures, and the differential equation of the lines of curvature, for the surfaces
(i) $2z = \frac{x^2}{a} + \frac{y^2}{b}$; (ii) $3z = ax^3 + by^3$; (iii) $z = c\tan^{-1}\frac{y}{x}$.
4. Examine the curvature, and find the lines of curvature, on the surface $xyz = abc$.
5. Find the principal direction and principal curvatures on the surface
$$x^1 = a(u^1+u^2);\quad x^2 = b(u^1-u^2);\quad x^3 = u^1u^2.$$
Show also that on the surface the parametric curves are asymptotic.
6. Find equations for the principal radii, the lines of curvature, and the first and second curvatures of the following surfaces:
   - (i) the conoid $x^1 = u^1\cos u^2;\ x^2 = u^1\sin u^2;\ x^3 = f(u^1)$;
   - (ii) the catenoid $x^1 = u^1\cos u^2;\ x^2 = u^1\sin u^2;\ x^3 = c\log\left(u^1 + \sqrt{(u^1)^2-c^2}\right)$;
   - (iii) the cylindroid $x^3((x^1)^2 + (x^2)^2) = 2mx^1x^2$; find also the lines of curvature and the principal curvatures;
   - (iv) the surface $2z = ax^2 + 2hxy + by^2$;

(v) the surface

$$x^1 = 3u^1(1 + (u^2)^2) \quad (u^1)^3;$$
$$x^2 = 3u^2(1 + (u^1)^2) \quad (u^2)^3;$$
$$x^3 = 3 \quad (u^1)^2 \quad (u^2)^2 \quad ;$$

Also show that the asymptotic lines are $u \quad v$ = constant.

(vi) the surface

$$\frac{x}{a} = \frac{1 + uv}{u + v}; \quad \frac{y}{b} = \frac{u \quad v}{u + v}; \quad \frac{z}{c} = \frac{1 \quad uv}{u + v};$$

(vii) the surface $xyz = a^3$:

7. Find the principal curvatures and the lines of curvature on the surface
$$z^2(x^2 + y^2) = c^4:$$

8. Prove that along a line of curvature of a conoid, one principal radius varies as the cube of the other.

9. Prove that if a plane cuts a surface everywhere at the same angle, the section is a line of curvature on the surface.

10. Prove that the only developable surface which have isometric lines of curvature are either conical or cylindrical.

11. Prove that the co-ordinate surfaces of every triply orthogonal curvilinear co-ordinate system in E^3 intersect along the lines of curvature of co-ordinate surfaces.

    Hints: Consider the surface x^3 = constant and take $x^1 = u^1; x^2 = u^2$ as surface co-ordinates on it. Show that along the co-ordinate lines u^1 = constant, u^2 = constant, $b_{12} = 0$ if $a_{12} = 0$:

12. Find the components of the curvature tensors R and R on $x^3 = f(x^1; x^2)$:

13. Prove that the Gaussian curvature k depends only on the coefficients of the first fundamental form (and their derivatives) but not on the second fundamental form.

14. Given an ellipsoid of revolution, whose surface is given by

$$x^1 = a\cos u^1 \sin u^2; \quad x^2 = a\sin u^1 \sin u^2; \quad x^3 = c\cos u^2;$$

where a and c are constants satisfying $a^2 > c^2$ and $x^1; x^2; x^3$ are orthogonal Cartesian co-ordinates. Show that

$$a_{11} = a^2\sin^2 u^2; \; a_{12} = 0; \quad a_{22} = a^2\cos^2 u^2 + c^2\sin^2 u^2;$$

$$b_{11} = \frac{ac\sin^2 u^2}{\sqrt{a^2\cos^2 u^2 + c^2\sin^2 u^2}}; \; b_{12} = 0; \; b_{22} = \frac{ac}{\sqrt{a^2\cos^2 u^2 + c^2\sin^2 u^2}}$$

and the total curvature K is given by

$$K = \kappa_1\kappa_2 = \frac{c^2}{(a^2\cos^2 u^2 + c^2\sin^2 u^2)^2}.$$

Discuss the lines of curvature on this surface.

15. Show that the lines of curvatures for the surface given by

$$(x^1)^2 + (x^2)^2 + (x^3)^2 = 1$$

are the parametric curves.

16. Show that the lines of curvatures for the surface given by

$$\mathbf{r} = (u\cos v, u\sin v, cv)$$

are given by $v = \pm\sinh^{-1}\frac{u}{c} + \text{constant}$. Also, show that on the surface the parametric curves are asymptotic lines.

17. Show that a system of confocal ellipses and hyperbolas are isometric lines in the plane.

18. Show that the umbilics of the surface

$$\left(\frac{x^1}{a}\right)^{2/3} + \left(\frac{x^2}{b}\right)^{2/3} + \left(\frac{x^3}{c}\right)^{2/3} = 1$$

lie on a sphere of radius $abc/(ab + bc + ca)$ whose centre is the origin.

19. If $a > b > c$, the ellipsoid $\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1$ has umbilici at the points

$$y = 0, \; x^2 = \frac{a^2(a^2 - b^2)}{a^2 - c^2}, \; z^2 = \frac{c^2(b^2 - c^2)}{a^2 - c^2}.$$

20. Show that the surface $4a^2z^2 = (x^2 - 2a^2)(y^2 - 2a^2)$ has a line of umbilics lying on the sphere $x^2 + y^2 + z^2 = 4a^2$.

21. Prove that, at any point of the surface, the sum of the radii of normal curvature in conjugate directions is constant.

22. Prove that the product of the radii of normal curvature in conjugate directions is a minimum for the lines of curvature.

23. Prove that the normal curvature in a direction perpendicular to an asymptotic line is twice the mean curvature.

24. Show that on the paraboloid $2z = \frac{x^2}{a^2} - \frac{y^2}{b^2}$ the asymptotic lines are $\frac{x}{a} \pm \frac{y}{b} = \text{constant}$.

25. Find the asymptotic lines on the surface

$$x = a(1+\cos u)\cot v; \ y = a(1+\cos u); \ z = \frac{a\cos u}{\sin v}:$$

26. Prove that the asymptotic lines of the right conoid

$$x^1 = u^1\cos u^2; x^2 = u^1\sin u^2; \ x^3 = f(u^2)$$

are given by u^2 = constant, $\frac{@f}{@u^2} = (u^{1})^2 c$: Hence, find the asymptotic lines of the cylindroid

$$x^1 = u^1\cos u^2; \ x^2 = u^1\sin u^2; \ x^3 = m\sin 2u^2:$$

Determine $f(u^2)$ so that on this conoid the parametric curves may be isometric lines.

27. Prove that the asymptotic lines of the catenoid $u^1 = c\cosh\frac{x^3}{c}$ lie on the cylinders

$$2u^1 = c \quad ae^{u^2} + \frac{1}{a}e^{\ \ u^2} \quad ; \text{where } a \text{ is arbitrary.}$$

Hints: Consider the parametric representation of the curve as

$$x^1 = u^1\cos u^2; x^2 = u^1\sin u^2; \ x^3 = f(u^1) = c\cosh^1 \ \frac{u^1}{c}:$$

28. Find the asymptotic lines on the surface $z = y\sin x$:

29. Prove that the asymptotic lines on the surface of revolution

$$x^1 = u^1\cos u^2; x^2 = u^1\sin u^2; \ x^3 = f(u^1)$$

are given by $f_{11}d(u^1)^2 + u^1 f_1 d(u^2)^2 = 0$: Write down the value of the torsions. Further if $u^1 = a\sin$ and $f(u^1) = a(\log\tan\frac{}{2} + \cos)$ the asymptotic lines are given by $du^2 = \frac{d}{\sin}$:

30. Find the asymptotic lines and torsions on the surface whose equation is

$$r = (x^1; x^2; x^3) = \quad x^1; \ x^2; \ f(x^1; x^2) \quad :$$

Hence, show that

(i) if $f(x^1; x^2) = x^2\sin x^1$, then the asymptotic line is $(x^2)^2\cos x^1 = c_1$:

(ii) if $f(x^1; x^2) = \frac{1}{2} \ \frac{(x^1)^2}{a^2} \quad \frac{(x^2)^2}{b^2}$, then the asymptotic line is $\frac{x^1}{a} \quad \frac{x^2}{b} = c_1$:

31. Prove that the generating straight lines of a cylinder or a cone are asymptotic curves on those surfaces.
32. Prove that the asymptotic lines on a minimal surface form an orthogonal system.
33. Prove that the indicatrix at a point of a surface $z = f(x; y)$ is a rectangular hyperbola if

$$(1 + p^2)t - 2pqs + (1 + q^2)r = 0:$$

Also, show that the asymptotic lines and torsions are

$$rdx^2 + 2sdxdy + tdy^2 = 0; \quad \tau = \pm\frac{\sqrt{s^2 - rt}}{1 + p^2 + q^2}:$$

34. Prove that the indicatrix at every point of a helicoid $z = c\tan^{-1}\frac{y}{x}$ is a rectangular hyperbola.
35. Show that the parametric curves are conjugate on the surface

$$x^3 = f(x^1) + f(x^2);$$

where x^1 and x^2 are parameters.
36. If a curve is a geodesic on the surface, prove that it is either a straight line or its principal normal is orthogonal to the surface at every point and conversely.
37. Prove that the normal curvature in a direction perpendicular to an asymptotic line is twice the mean normal curvature.
38. Prove that the sum of the normal curvatures in two directions at right angles is constant, and equal to the sum of the principal curvatures.
39. Prove that, at each non-umbilical point of a surface there exist two mutually orthogonal directions for which the normal curvature attains its extreme values.
40. Show that the helicoid

$$x^1 = u^1\cos u^2; \; x^2 = u^1\sin u^2; \; x^3 = au^2$$

is a surface of negative curvature.
41. If S is a surface of revolution

$$x^1 = u^1\cos u^2; \; x^2 = u^1\sin u^2; \; x^3 = f(u^1)$$

with $f(u^1)$ of class C^2; show that the points on a surface of revolution S for which $f'f'' > 0$ are elliptic; those for which $f'f'' < 0$ are hyperbolic; and if $f'' = 0$; then S is a cone.

42. Find the differential equation of the asymptotic curves of a surface of revolution

$$x^1 = u^1 \cos u^2;\ x^2 = u^1 \sin u^2;\ x^3 = f(u^1)$$

and determine the location of elliptic, parabolic, and hyperbolic points on this surface.

43. Prove that the co-ordinate curves of any allowable co-ordinate system on a surface S coincide with the lines of curvature if and only if for this system $a_{12} = 0 = b_{12}$ at any point where those co-ordinates are allowable.
44. Prove that at elliptic points the Gaussian curvature is positive, at parabolic ones it vanishes, and at hyperbolic ones it is negative.
45. Prove that if every point of a surface S which has a representation of class ≥ 3 is an umbilic, S is a plane or a sphere.
46. Show that on a cylinder $x^1 = c\cos u^1;\ x^2 = c\sin u^1;\ x^3 = u^2$ one distinct real asymptotic direction is given by u^1 curve.
47. Prove that the osculating plane to an asymptotic line which is not a straight line coincides with the tangent plane.
48. Prove that if every point of the surface S is parabolic, then S is developable.
49. Prove that any point of the following ellipsoid is elliptic

$$x^1 = a\cos u^1 \cos u^2;\ x^2 = b\sin u^1 \cos u^2;\ x^3 = c\sin u^2:$$

50. Prove that any point of a cylinder or of a cone is parabolic.
51. If S is a surface of revolution

$$x^1 = u^1 \cos u^2; x^2 = u^1 \sin u^2;\ x^3 = f(u^1)$$

with $f(u^1)$ of class C^2; show that a parallel surface $\overline{S}$ is also a surface of revolution.

52. Show that the meridians and parallels on a sphere form an isometric system, and determine the isometric parameters.
53. On the surface formed by the revolution of a parabola about its directrix, one principal curvature is double the other.
54. Find the surface of revolution for which

$$ds^2 = du^2 + (a^2 - u^2)dv^2:$$

55. If the surface of revolution is a minimal surface,

$$u\frac{d^2f}{du^2} + \frac{df}{du}\left[1 + \left(\frac{df}{du}\right)^2\right] = 0:$$

Hence, show that the only real minimal surface of revolution is that formed by the revolution of a catenary about its directrix.

56. Find the equations of the helicoid generated by a circle of radius a, whose plane passes through the axis; and determine the lines of curvature on the surface.
57. Prove that the null lines are conjugate if and only if the surface is minimal.
58. Show that the only minimal surface of the type $z = f(x) + F(y)$ is the surface $az = \log\cos(ax) - \log\cos(ay)$.
59. Show that the surface $\sin az = \sinh ax \sinh ay$ is minimal.
60. Show that the surfaces

$$x^1 = u^1\cos u^2;\ \ x^2 = u^1\sin u^2;\ \ x^3 = cu^2$$

and

$$x^1 = u^1\cos u^2;\ \ x^2 = u^1\sin u^2;\ \ x^3 = c\cosh^{-1}\frac{u^1}{c}$$

are applicable.
61. Find the first and second curvatures for the spherical image.
62. Prove that the osculating planes of a line of curvature and of its spherical image at corresponding points are parallel.
63. Show that the lines of curvature of a surface of revolution remains isometric in their spherical representation.
64. Show that the spherical images of the asymptotic lines on a minimal surface, as well as the asymptotic lines themselves, are an isometric system.
65. Show that the helicoids

$$x^1 = u^1\cos u^2;\ \ x^2 = u^1\sin u^2;\ \ x^3 = cu^2 + c\int\sqrt{\frac{(u^1)^2 + c^2}{(u^1)^2 - c^2}}\,\frac{du^1}{u^1}$$

is a minimal surface.

Chapter 9
Complex Numbers

9.1 Definition and Properties of Complex Numbers

9.1.1 Imaginary Numbers

The square of positive as well as negative real numbers is always a positive real number. For example, $3^2 = (\quad 3)^2 = 9$. The root of a positive number is therefore a positive or negative number. We now introduce a new type of number whose square always gives a negative real number: they are called *imaginary numbers*.

Definition The unit of imaginary numbers is the number j with the property that

$$\mathrm{j}^2 = \quad 1 \qquad (9.1)$$

The imaginary unit j corresponds to 1 for real numbers.

An arbitrary imaginary number is made up of the imaginary unit j and any real number y; thus $y\mathrm{j}$ is the general form for an imaginary number.

We know that we cannot extract the root of a negative number when dealing with real numbers; nevertheless, we can factorise the root of a negative number thus:

$$\overline{\quad 5} = \quad \overline{5(\quad 1)} = \quad \overline{5} \times \quad \overline{\quad 1}$$

Since $\mathrm{j}^2 = \quad 1$, it follows that $\mathrm{j} = \quad \overline{\quad 1}$; hence $\quad \overline{5} \times \quad \overline{\quad 1} = \mathrm{j} \quad \overline{5}$.

The root of a negative number is an imaginary number. Moreover, with $\mathrm{j}^2 = \quad 1$, we can simplify higher powers of j.

K. Weltner, W. J. Weber, J. Grosjean, P. Schuster, *Mathematics for Physicists and Engineers*
ISBN 978-3-642-00172-7 ' Springer 2009

The ordinary rules of algebra extend to imaginary numbers. In addition one must remember that $j^2 = -1$, i.e.

$$
\begin{aligned}
j^1 &= j\\
j^2 &= -1\\
j^3 &= j^2 \times j = -j\\
j^4 &= j^2 \times j^2 = 1
\end{aligned}
$$

9.1.2 Complex Numbers

The sum z of a real number x and an imaginary number jy is called a *complex number*, complex meaning "composed". Thus

$$z = x + jy$$

where x is the real part of z and y is the imaginary part of z.

If we replace j by $-j$, we obtain a different complex number z^* given by

$$z^* = x - jy$$

z^* is called the *complex conjugate* of z.

A complex number has the value zero only if both the real part and the imaginary part are zero.

9.1.3 Fields of Application

The most obvious property of imaginary numbers is that we can "extract" the root of a negative number, which means we obtain an expression which we can handle. This property enables us, in principle, to solve equations of any degree. Consider, for instance, the quadratic equation

$$ax^2 + bx + x = 0$$

We have seen that it is unsolvable in terms of real x if $b^2 < 4ac$, i.e. when the radicand $b^2 - 4ac$ becomes negative. The solution in terms of complex x is

$$x_{1,2} = \frac{1}{2a}\left(-b - j\sqrt{4ac - b^2}\right)$$

Complex numbers are important in the solution of differential equations which are dealt with in Chap. 10. They are also a useful concept in electrical engineering, and they are indispensable in the study of quantum physics.

9.1.4 Operations with Complex Numbers

When handling complex numbers there are two rules to remember:

The complex number $x + jy$ is zero if and only if $x = 0$ and $y = 0$.

Complex numbers obey the ordinary rules of algebra, in addition $j^2 = \quad 1$.

Addition and Subtraction of Complex Numbers

Rule The sum of complex numbers is obtained by adding real and imaginary parts separately.
The difference of complex numbers is obtained by subtracting real and imaginary parts separately.

Let	*Example*
$z_1 = x_1 + jy_1$	$z_1 = 6 + 7j$
$z_2 = x_2 + jy_2$	$z_2 = 3 + 4j$
Then their sum is	
$z_1 + z_2 = (x_1 + jy_1) + (x_2 + jy_2)$	$z_1 + z_2 = (6 + 7j) + (3 + 4j)$
$= (x_1 + x_2) + j(y_1 + y_2)$	$= 9 + 11j$
Their difference is	*Example*
$z_1 \quad z_2 = (x_1 \quad x_2) + (y_1 \quad y_2)j$	$z_1 \quad z_2 = 3 + 3j$

Product of Complex Numbers

Rule The product z_1, z_2 of two complex numbers is obtained by simple multiplication of the terms, taking into account $j^2 = \quad 1$.

General expression	*Example*
$z_1 z_2 = (x_1 + jy_1)(x_2 + jy_2)$	$z_1 z_2 = (6 + 7j)(3 + 4j)$
$= x_1 x_2 + jx_1 y_2 + jy_1 x_2 + j^2 y_1 y_2$	$= 18 + 24j + 21j \quad 28$
$= (x_1 x_2 \quad y_1 y_2) + j(x_1 y_2 + x_2 y_1)$	$= \quad 10 + 45j$

Division of Complex Numbers

Rule Division of a complex number by another complex number is carried out by multiplying numerator and denominator by the conjugate of the divisor to transform the latter into a real number. Note that the denominator then appears as the sum of two squares.

General expression

$$\frac{z_1}{z_2} = \frac{x_1 + jy_1}{x_2 + jy_2} = \frac{(x_1 + jy_1)(x_2 - jy_2)}{(x_2 + jy_2)(x_2 - jy_2)}$$

$$= \frac{(x_1x_2 + y_1y_2) - j(x_1y_2 - y_1x_2)}{x_2^2 + y_2^2}$$

The conjugate of z_2 is $z_2^* = x_2 - jy_2$

Example

$$\frac{z_1}{z_2} = \frac{6 + 7j}{3 + 4j} = \frac{(6 + 7j)(3 - 4j)}{(3 + 4j)(3 - 4j)}$$

$$= \frac{10 - 3j}{25} = \frac{2}{5} - \frac{3}{25}j$$

9.2 Graphical Representation of Complex Numbers

9.2.1 Gauss Complex Number Plane: Argand Diagram

The complex number $z = x + jy$ can be represented in an $x - y$ coordinate system by placing the real part along the x-axis and the imaginary part along the y-axis in a similar way to the components of a vector. Figure 9.1 shows this.

We obtain a point P(z) in this plane which corresponds to the complex number z. This plane is called the Gauss number plane, better known as the *Argand diagram*. In this way we have produced a geometrical picture of a complex number.

Example Where is the point in the Argand diagram corresponding to the complex number $z = 4 - 2j$? Figure 9.2 shows the answer.

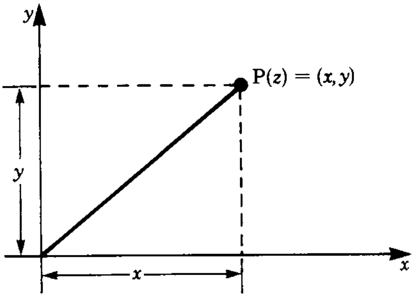

Fig. 9.1

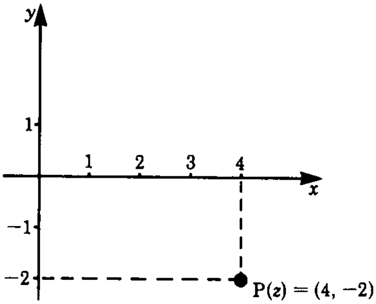

Fig. 9.2

Addition

$$z_3 = z_1 + z_2$$

If $z_1 = 6 + 3j$ and $z_2 = 2 + 5j$ we know that the sum $z_3 = 8 + 8j$. This addition may be represented in an Argand diagram, as shown in Fig. 9.3.

To obtain the complex number z_3, we first draw the two complex numbers z_1 and z_2 as vectors as shown. Then we shift vector z_2 parallel to itself in such a way that its tail is made to coincide with the tip of vector z_1. The tip of vector z_2 locates the tip of the required vector or complex number z_3 whose magnitude is given by the length OP. This construction is based on the parallelogram rule for the addition of vectors. The same result is obtained if we shift z_1 instead of z_2. We dealt with vectors in Chap. 1, so this construction should not be new to the reader.

To add more than two complex numbers we draw a polygon by joining the vectors tip to tail. The tip of the closing vector represents the required complex number.

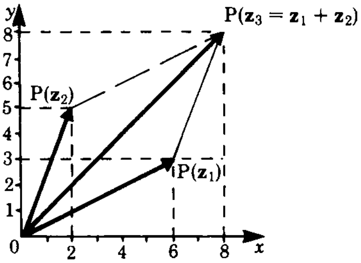

Fig. 9.3

Subtraction

$$z_3 = z_1 - z_2 = z_1 + (-z_2)$$

The problem of the subtraction of two complex numbers can be transformed into one of addition if to one complex number we add the negative of the other.

9.2.2 Polar Form of a Complex Number

Instead of specifying a complex number by means of the coordinates x and y, we could specify it by means of a distance r from the origin of the coordinates and an angle , as shown in Fig. 9.4 x and y are the Cartesian coordinates, and r and are the polar coordinates.

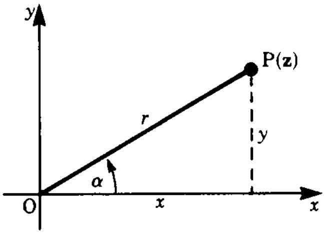

Fig. 9.4

From the figure we see that

$$x = r\cos$$
$$y = r\sin$$

Substituting in the expression for the complex number, $z = x + jy$, gives

$$z = r(\cos \quad + j\sin \quad) \tag{9.2}$$

This expresses a complex number in terms of the trigonometric functions. It follows that the conjugate z of the complex number z is

$$z \;= r(\cos \quad j\sin \quad)$$

If we know r and we can calculate x and y from the above equations. If on the other hand we know x and y and we want to express a complex number in polar form, it follows from Fig. 9.4 that

$$r = \sqrt{x^2 + y^2} \quad \text{taking the positive value only}$$
$$= \tan^{\;1} \frac{y}{x}$$

r is known as the *modulus* and as the *argument*.

Table 9.1 illustrates the values taken by according to the sign of x and y.

Table 9.1

x	y	tan	P(z) lies in	in the range
positive	positive	positive	1st quadrant	0 to $\frac{}{2}$
negative	positive	negative	2nd quadrant	$\frac{}{2}$ to
negative	negative	positive	3rd quadrant	to $\frac{3}{2}$
positive	negative	negative	4th quadrant	$\frac{3}{2}$ to 2

Example Express the complex number $z = 1 \quad j$ in polar form.
$z = 1 \quad j$ means that $x = 1$ and $y = \quad 1$.

Hence $$r = \overline{x^2 + y^2} = \overline{1+1} = \overline{2}$$
$$= \tan^{1} \frac{1}{1} = \tan^{1}(\quad 1) = \frac{3}{4} \quad \text{or} \quad \frac{7}{4}$$

We represent the complex number in the Argand diagram (Fig. 9.5) and find that it lies in the fourth quadrant. It follows then that

$$= \frac{7}{4}$$

Thus the complex number $z = 1 \quad j$ can be written in polar form:

$$z = \overline{2} \quad \cos\frac{7}{4} + j\sin\frac{7}{4}$$

Example Express the complex number $z = 6j$ in polar form.
In this case, $z = x + jy \quad 0 + 6j$, i.e. $x = 0$. Consequently $r = 6$

$$\tan \quad = \frac{y}{x} = \frac{6}{0} = d, \quad \text{i.e.} \quad = \frac{}{2} \quad \text{or} \quad \frac{3}{2}$$

To determine , the complex number is shown in Fig. 9.6. It follows, therefore, that $= \frac{}{2}$. In polar form the complex number is

$$z = 6 \quad \cos\frac{}{2} + j\sin\frac{}{2}$$

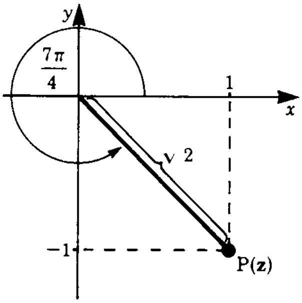

Fig. 9.5

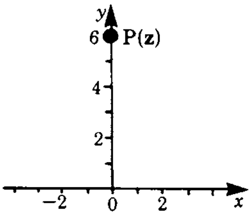

Fig. 9.6

9.3 Exponential Form of Complex Numbers

9.3.1 Euler's Formula

It is also possible to express a complex number in the form

$$z = re^{j} \tag{9.3}$$

As before, r is the modulus of z and is the argument. We can show that it is equivalent to the polar form of a complex number:

$$z = r(\cos \quad + j\sin \quad)$$

In other words we want to prove that

$$re^{j} \quad = r(\cos \quad + j\sin \quad)$$

Dividing by r gives

$$e^{j} \quad = \cos \quad + j\sin$$

In Chap. 8, Sect. 8.2, we showed that the expansion for e^x is

$$e^x = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \frac{x^4}{4!} + \cdots$$

This expansion remains valid if we replace x by j . Remembering that $j^2 = \quad 1$, we obtain

$$e^{j} \quad = 1 + j \qquad \frac{{}^2}{2!} \quad j\frac{{}^3}{3!} + \frac{{}^4}{4!} + j\frac{{}^5}{5!}\cdots$$

We also showed that

$$\sin \quad = \qquad \frac{{}^3}{3!} + \frac{{}^5}{5!} \quad \cdots$$

Hence

$$j\sin \quad = j \quad j\frac{{}^3}{3!} + j\frac{{}^5}{5!} \quad \cdots$$

$$\cos \quad = 1 \quad \frac{{}^2}{2!} + \frac{{}^4}{4!} \quad \cdots$$

Comparing these expressions, we obtain

$$\cos \quad + j\sin \quad = 1 + j \qquad \frac{{}^2}{2!} \quad j\frac{{}^3}{3!} + \frac{{}^4}{4!} + j\frac{{}^5}{5!} \quad \cdots = e^{j}$$

Euler’s formula

$$e^{j} = \cos \quad + j \sin \qquad (9.4)$$

This enables us to express a complex number in a third way.

A table giving the various forms in which complex numbers can be expressed will be found in the appendix at the end of this chapter.

9.3.2 Exponential Form of the Sine and Cosine Functions

The conjugate complex number of e^{j} is obtained by replacing j by j, so that if $z = e^{j}$ then $z = e^{\ j}$.

Now we will try to express the sine and cosine function in terms of e^{j} .

According to Euler s formula, we have

$$e^{j} = \cos \quad + j \sin$$
$$e^{\ j} = \cos \quad j \sin$$

Adding both equations gives

$$\cos \quad = \frac{1}{2}(e^{j} + e^{\ j}) = \cosh j$$

Subtracting both equations gives

$$\sin \quad = \frac{1}{2j}(e^{j} \quad e^{\ j}) = \frac{1}{j}\sinh j$$

9.3.3 Complex Numbers as Powers

Given the complex number $z = x + jy$, we wish to calculate the modulus and argument of

$$w = e^{z}$$

Substituting for z, we have

$$w = e^{(x+jy)} = e^{x} e^{jy} \quad r e^{j}$$

Comparing the last two expressions, it follows that $r = e^{x}$ and $jy = j$. Hence the modulus of w is e^{x}, and the argument of w is y.

Example If $z = 2 + j \ /2$, calculate $w = e^{z}$.

$$w = e^{z} = e^{(2+j \ /2)} = e^{2} e^{j \ /2}$$

Hence the modulus is $r = e^2$ and the argument is $\ = \ /2$, and we have

$$w = e^2 \left(\cos \frac{}{2} + j \sin \frac{}{2} \right) = j e^2$$

The solution is shown in the Argand diagram (Fig. 9.7).

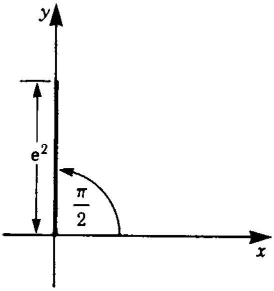

Fig. 9.7

Example If $z = \ 2 + j3 \ /4$, calculate $w = e^z$.

$$w = e^{\ 2 + j\frac{3}{4}} = e^{\ 2} e^{j\frac{3}{4}}$$

$$r = e^{\ 2} \quad \text{and} \quad = \frac{3}{4}$$

Hence $$w = e^{\ 2} \left(\cos \frac{3}{4} + j \sin \frac{3}{4} \right)$$

$$= e^{\ 2} \left(\frac{1}{\sqrt{2}} + j \frac{1}{\sqrt{2}} \right)$$

This solution is shown in the Argand diagram (Fig. 9.8).

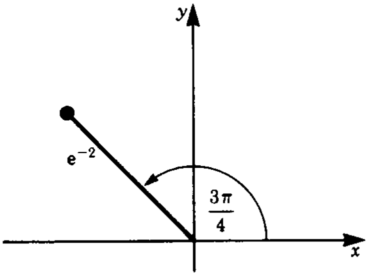

Fig. 9.8

Suppose now that z is a function of some parameter t. The simplest case is that of the linear function where a and b are constants.

$$z(t) = at + jbt$$

One important interpretation of t in practice is the time, so that $z(t)$ grows with time, i.e. the real part and the imaginary part grow with time.

Substituting for z in $w = e^z$ gives $w(t) = e^{(at+jbt)} = e^{at}e^{jbt}$

Using Euler s formula, we get $w(t) = e^{at}(\cos bt + j \sin bt)$

To examine the behaviour of this function, we can consider the real and the imaginary parts separately and represent each one graphically as a function of the time t.

The real part of $w(t)$ is $e^{at} \cos bt$. It is the product of an exponential function and a trigonometric function of period $p = 2\quad /b$.

If a is positive then $w = e^{at} \cos bt$ represents a vibration whose amplitude grows exponentially with time, as shown in Fig. 9.9.

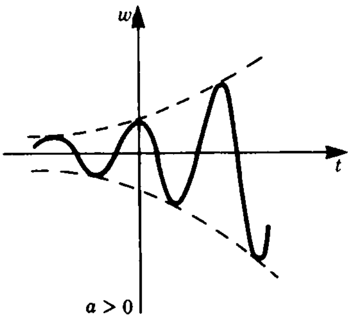

Fig. 9.9

If a is negative then $w = e^{at} \cos bt$ represents a vibration whose amplitude decreases exponentially with time; the vibration is said to be damped and is shown below in Fig. 9.10.

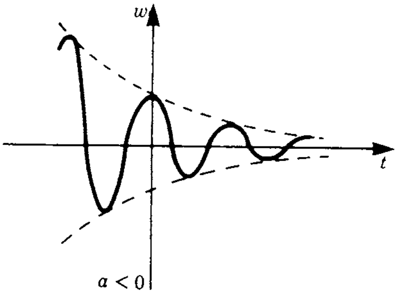

Fig. 9.10

The imaginary part of $w(t)$ is $e^{at}\sin bt$. It is also the product of an exponential function and a trigonometric function whose graphical representation is similar to Fig. 9.9 or Fig. 9.10, depending on the sign of a.

The mathematical solution of vibration problems is often simplified by means of complex numbers. Thus, in solving a practical problem, we start by considering the physical situation consisting of real quantities. We then perform all calculations using complex numbers and finally consider and interpret the results of the real and imaginary parts.

9.3.4 Multiplication and Division in Exponential Form

Addition and subtraction of complex numbers are best carried out using the form $z = x + jy$. Multiplication and division, on the other hand are best carried out by expressing the complex numbers either in exponential form or in polar form.

Consider two complex numbers

$$z_1 = r_1 e^{j\varphi_1} \quad \text{and} \quad z_2 = r_2 e^{j\varphi_2}$$

Multiplying gives

$$z = z_1 z_2 = r_1 e^{j\varphi_1} r_2 e^{j\varphi_2} = r_1 r_2 e^{j(\varphi_1 + \varphi_2)} \tag{9.5}$$

Here we use the power rule $a^n a^m = a^{n+m}$.

Dividing gives

$$z = \frac{z_1}{z_2} = \frac{r_1 e^{j\varphi_1}}{r_2 e^{j\varphi_2}} = \frac{r_1}{r_2} e^{j(\varphi_1 - \varphi_2)} \tag{9.6}$$

Here we use the power rule $a^n / a^m = a^{n-m}$.

Rule To multiply (or divide) complex numbers, we multiply (or divide) the moduli and add (or subtract) the arguments.

9.3.5 *Raising to a Power, Exponential Form*

We have

$$z^n = (re^{j\alpha})^n = r^n e^{jn\alpha} \tag{9.7}$$

Rule To raise a complex number to a given power we raise the modulus to that power and multiply the argument by that power.

Figure 9.11 shows the points z and z^2 in the complex plane with $r = 2$.

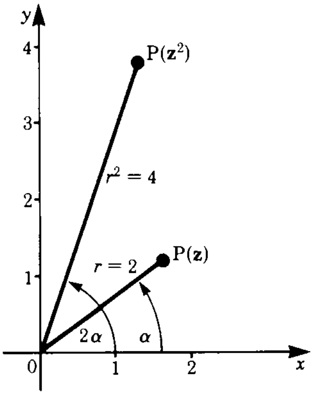

Fig. 9.11

In the case of $z^{1/n}$ we have

$$z^{1/n} = \sqrt[n]{z} = \sqrt[n]{re^{j\alpha}} = \sqrt[n]{r}\, e^{j\alpha/n} \tag{9.8}$$

Rule To extract the root of a complex number, we find the root of the modulus and divide the argument by the index.

9.3.6 *Periodicity of* $re^{j\alpha}$

We should like to mention the fact, perhaps surprising to the reader, that the complex number

$$z = re^{j\alpha}$$

is identical to

$$z = re^{j(\alpha+2\pi)}$$

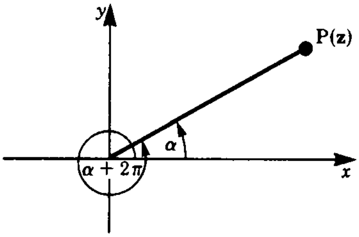

Fig. 9.12

If we examine Fig. 9.12 we can see that the same point P(z) is obtained whether the angle is α or $\alpha + 2\pi$. In fact we could equally take the angle to be $\alpha + 4\pi$, $\alpha + 6\pi$, $\alpha - 2\pi$, $\alpha - 4\pi$, etc. Hence, generally

$$re^{j\alpha} = re^{j(\alpha + 2\pi k)}$$

where $k = \pm 1, \pm 2, \pm 3$ etc.

In particular we have $1 = e^{j2\pi}$

9.3.7 *Transformation of a Complex Number From One Form into Another*

Transformation from the Algebraic Form into the Exponential Form

The transformation from $x + jy$ into $re^{j\alpha}$ is based on the relationships derived in Sect. 9.2.2, i.e.

$$r = \sqrt{x^2 + y^2}, \quad \tan\alpha = \frac{y}{x}$$

Example Convert the complex number $z = -\sqrt{5} + 2j$ to the exponential form.

$$r = \sqrt{(-\sqrt{5})^2 + 2^2} = 3$$

$$\tan\alpha = \frac{2}{-\sqrt{5}} = -0.894$$

The angle is in the second quadrant; therefore $\alpha = 138.19°$ or 0.768π radians.

Transformation of the Exponential Form into the Algebraic Form

Since $z = re^{j\alpha} = r(\cos\alpha + j\sin\alpha) = x + jy$

then $x = r\cos\alpha$

$y = r\sin\alpha$

Example Convert the expression $z = e^{(0.5+1.3j)}$ to the algebraic form.

$$\begin{aligned} z &= e^{(0.5+1.3j)} = e^{0.5}e^{1.3j} \\ x &= e^{(0.5)}\cos 1.3 = 0.441 \\ y &= e^{(0.5)}\sin 1.3 = 1.589 \end{aligned}$$

Hence $z = 0.441 + 1.589j$

9.4 Operations with Complex Numbers Expressed in Polar Form

In the previous section, the rules for operations with complex numbers have been derived using the exponential form. We will now show that the same rules are obtained if we express the complex numbers in polar form. We make use of the addition theorems for trigonometric functions given in Chap. 3, Sect. 3.6.6.

9.4.1 Multiplication and Division

Let z_1 and z_2 be expressed in polar form so that

$$\begin{aligned} z_1 &= r_1(\cos\ {}_1 + j\sin\ {}_1) \\ z_2 &= r_2(\cos\ {}_2 + j\sin\ {}_2) \end{aligned}$$

Multiplication

$$\begin{aligned} z_1 z_2 &= r_1 r_2(\cos\ {}_1 + j\sin\ {}_1)(\cos\ {}_2 + j\sin\ {}_2) \\ &= r_1 r_2[(\cos\ {}_1 \cos\ {}_2 \quad \sin\ {}_1 \sin\ {}_2) + j(\sin\ {}_1 \cos\ {}_2 + \cos\ {}_1 \sin\ {}_2)] \end{aligned}$$

Using the addition formulae for the sine and cosine functions,

$$\begin{aligned} z_1 z_2 &= r_1 r_2[\cos(\ {}_1 + \ {}_2) + j\sin(\ {}_1 + \ {}_2)] \\ &= r(\cos\ \ + j\sin\ \ ) \end{aligned} \tag{9.9}$$

Thus the modulus r of the product equals $r_1 r_2$, and the argument is $(\ {}_1 + \ {}_2)$.

This is exactly in accordance with the rule derived in the previous section: to multiply complex numbers we multiply the moduli and add the arguments.

Figure 9.13 illustrates geometrically the multiplication of complex numbers. Draw a triangle OPP_1 similar to the triangle OP_2Q (Q has coordinates 1, 0), then

$$\frac{z}{z_1} = \frac{z_2}{1}, \quad \text{hence} \quad z = z_1 z_2$$

Also = angle QOP = ${}_1 + {}_2$

α_1
α_2

Fig. 9.13

Division

Both the numerator and the denominator are multiplied by the conjugate of the divisor.

$$\frac{z_1}{z_2} = \frac{r_1(\cos\ {}_1 + j\sin\ {}_1)}{r_2(\cos\ {}_2 + j\sin\ {}_2)}\frac{r_2(\cos\ {}_2 \quad j\sin\ {}_2)}{r_2(\cos\ {}_2 \quad j\sin\ {}_2)}$$

Using the addition formulae for the sine and cosine functions,

$$\frac{z_1}{z_2} = \frac{r_1}{r_2}[\cos(\ {}_1 \quad {}_2) + j\sin(\ {}_1 \quad {}_2)] \tag{9.10}$$

Thus the modulus of the quotient equals $\frac{r_1}{r_2}$, and the argument is $(\ {}_1 \quad {}_2)$.

Again this is in accordance with the rule derived in the previous section: to divide complex numbers we divide the moduli and subtract the arguments.

Figure 9.14 illustrates the division of complex numbers by a reasoning similar to that for multiplication.

9.4.2 Raising to a Power

We saw earlier that $z_1 z_2 = r_1 r_2[\cos(\ _1 + \ _2) + j\sin(\ _1 + \ _2)]$

If we now let $z_1 = z_2 = z, r_1 = r_2 = r$ and $\ _1 = \ _2 = \ $ it follows that

$$z^2 = r^2(\cos 2\ \ + j\sin 2\ \ )$$

Similarly

$$z^3 = r^2(\cos 2\ \ + j\sin 2\ \ )r(\cos\ \ + j\sin\ \ )$$

$$= r^3(\cos 3\ \ + j\sin 3\ \ )$$

The general expression is

$$z^n < \ = r^n(\cos n\ \ + j\sin n\ \ ) \tag{9.11}$$

Rule To raise a complex number to a given power, we raise the modulus to that power and multiply the argument by that power.

By setting $r = 1$ we have

$$(\cos\ \ + j\sin\ \ )^n = \cos n\ \ + j\sin n$$

This is known as *De Moivre's theorem*.

9.4.3 Roots of a Complex Number

De Moivre s theorem holds true for *positive, negative* and *fractional powers*. We can, therefore, use this fact to determine all the distinct roots of any number.

Since $x + jy = r(\cos\ \ + j\sin\ \ )$, then, by De Moivre s theorem, it follows that

$$\sqrt[n]{x + jy} = \sqrt[n]{r}\ \ \cos\frac{\ }{n} + j\sin\frac{\ }{n}$$

However, using this equation, we obtain one root only. In order to obtain all the roots we must consider the fact that the cosine and sine functions are periodic functions of period $2\ $ radians or $360\ $. Thus we can write

$$(\cos\ \ + j\sin\ \ )^n = [\cos(\ \ + 2\ \ k) + j\sin(\ \ + 2\ \ k)]^n$$

$$= \cos(n\ \ + 2\ \ nk) + j\sin(n\ \ + 2\ \ nk)$$

$$\text{where}\quad k = 0, -1, -2, -3, \bullet\bullet\bullet$$

When raising a complex number to an integral power there is no ambiguity: the result is independent of periodicity. But extracting the roots of a complex number means raising it to a fractional power. Now periodicity becomes important, and we have

$$\sqrt[n]{x + jy} = \sqrt[n]{r}\ \cos\ \ \frac{}{n} + \frac{2}{n}k\ \ + j\sin\ \ \frac{k}{n} + \frac{2}{n}k$$

$$\text{where}\quad k = 0, -1, -2, \bullet\bullet\bullet \qquad (9.12)$$

Rule The nth roots of a complex number are obtained by extracting the nth root of the modulus and dividing the argument by n. Due to the periodicity of the trigonometric functions, there are n solutions.

By giving k the values $0, 1, 2, 3, \bullet\bullet\bullet, (n \quad 1)$, we obtain the n different roots of a complex number; for example,

$$k = 0, \quad z_1 = \sqrt[n]{r}\ \ \cos\frac{}{n} + j\sin\frac{}{n}$$

$$k = 1, \quad z_2 = \sqrt[n]{r}\ \ \cos\ \ \frac{}{n} + \frac{2}{n}\ \ + j\sin\ \ \frac{}{n} + \frac{2}{n}$$

$$k = 2 \quad, z_3 = \sqrt[n]{r}\ \ \cos\ \ \frac{}{n} + \frac{4}{n}\ \ + j\sin\ \ \frac{}{n} + \frac{4}{n}$$

and so on. With $k = n$, we would obtain the same value as with $k = 0$; also we would not obtain any new values for $k > n$ or $k = \quad 1, \quad 2, \quad 3, \bullet\bullet\bullet$. The root corresponding to $k = 0$ is called the *principal value*.

Example Calculate the four roots of

$$z^4 = \cos\frac{2}{3} + j\sin\frac{2}{3}$$

In this case $r = 1$ and $n = 4$; hence

$$z^4 = \cos\ \ \frac{}{6} + \frac{2}{4}k\ \ + j\sin\ \ \frac{}{6} + \frac{2}{4}k$$

$$= \cos\ \ \frac{}{6} + \frac{}{2}k\ \ + j\sin\ \ \frac{}{6} + \frac{}{2}k$$

The roots are

$$k = 0, \quad z_1 = \cos\frac{}{6} + j\sin\frac{}{6} = \frac{1}{2}\ \ \overline{3} + \frac{1}{2}j$$

$$k = 1, \quad z_2 = \cos\frac{4}{6} + j\sin\frac{4}{6} = \quad \frac{1}{2} + \frac{\overline{3}}{2}j$$

$$k = 2, \quad z_3 = \cos\frac{7}{6} + j\sin\frac{7}{6} = \quad \frac{\overline{3}}{2} \quad \frac{1}{2}j$$

$$k = 3, \quad z_4 = \cos\frac{10}{6} + j\sin\frac{10}{6} = \frac{1}{2} \quad \frac{\overline{3}}{2}j$$

The roots z_1 and z_3, as well as z_2 and z_4, are opposite to each other; moreover, we can see that the argument, starting from the principal value, is successively increased by $/2$. Figure 9.15 shows all the values on a circle of radius 1. They form a square.

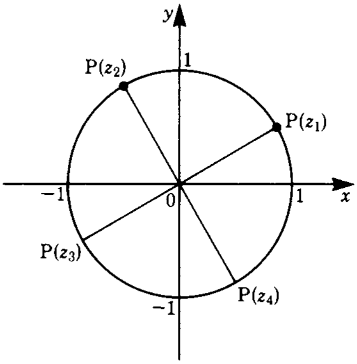

Fig. 9.15

All the nth roots of a complex number of modulus 1 have modulus 1. When depicted in an Argand diagram they form the vertices of a regular n-sided polygon inscribed in a unit circle.

Appendix

Summary of operations with complex numbers

Designation	Formulae
Imaginary unit j Imaginary number	$j^2 = \quad 1$ $\quad = jy \; (y \text{ real})$
Complex number z in arithmetic form	$z = x + jy \quad (x, y \text{ real})$ x = real part y = imaginary part
Complex conjugate	$z \; = x \quad jy$
Complex numbers in polar form	$z = r(\cos \quad + j \sin \quad)$
Transformation $(x, y) \quad (r, \quad)$	$x = r \cos \qquad r = \quad \overline{x^2 + y^2}$ $y = r \sin \qquad \tan \quad = y/x$
Complex number in exponential form Euler s formula	$z = r e^{j}$ $e^{j} \quad = \cos \quad + j \sin$
Exponential form for cosine and sine functions	$\cos \quad = \frac{1}{2}(e^{j} \quad + e^{\; j} \;) = \cosh j$ $\sin \quad = \frac{1}{2j}(e^{j} \qquad e^{\; j} \;) = \frac{1}{j} \sinh j$
Periodicity of complex numbers	$z \; = r e^{j}$ $\quad = r e^{j(\; + 2k \;)} \quad (k = -1, -2, -3, \bullet\bullet\bullet)$
Multiplication and division in exponential form	$z_1 = r_1 e^{j \; 1}, z_2 = r_2 e^{j \; 2}$ $z_1 z_2 = r_1 r_2 e^{j(\; 1 + \; 2)}$ $\frac{z_1}{z_2} = \frac{r_1}{r_2} e^{j(\; 1 \quad 2)}$
Raising to a power and extracting roots in exponential form	$z = r e^{j}$ $z^n = r^n e^{jn}$ ${}^n \overline{z} = {}^n \overline{r} e^{j[(\; + 2 \; k)/n]} (k = 0, -1, -2, \bullet\bullet\bullet)$
Multiplication and division in polar form	$z_1 = r_1(\cos \; {}_1 + j \sin \; {}_1)$ $z_2 = r_2(\cos \; {}_2 + j \sin \; {}_2)$ $z_1 z_2 = r_1 r_2[\cos(\; {}_1 + \; {}_2) + j \sin(\; {}_1 + \; {}_2)]$ $\frac{z_1}{z_2} = \frac{r_1}{r_2}[\cos(\; {}_1 \quad {}_2) + j \sin(\; {}_1 \quad {}_2)]$
Raising to a power and extracting roots in polar form	$z = r(\cos \quad + j \sin \quad)$ $z^n = r^n[\cos n \quad + j \sin n \quad]$ ${}^n \overline{z} = {}^n \overline{r} \quad \cos \quad \frac{}{n} + \frac{2 \; k}{n} \quad + j \sin \quad \frac{}{n} + \frac{2 \; k}{n}$ $(k = 0, -1, -2, \bullet\bullet\bullet)$

Exercises

9.1 Definition and Properties of Complex Numbers

1. Express the following in terms of j:

   (a) $\overline{4\quad 7}$ (b) $\overline{\quad 144}$

   (c) $\frac{\overline{5}}{\overline{\quad 4}}$ (d) $\overline{4(\quad 25)}$

2. Compute

   (a) j^8 (b) j^{15}

   (c) j^{45} (d) $(\quad j)^3$

3. Evaluate

   (a) $\overline{\quad 48} + \overline{\quad 75} \qquad \overline{\quad 27}$ (b) $\overline{\quad 12} \qquad \overline{\quad 8} + \overline{\quad 0.6}$

   (c) $\overline{\quad 3}\ \overline{\quad 3}$ (d) $\overline{\quad a}\ \overline{+b}$

   (e) $5j^3 2j^6$ (f) $(\quad j)^3 j^2$

   (g) $8j/2j$ (h) $1/j\ ^3$

   (i) $6j/j^7 \quad \overline{3}$ (j) $1/j^5 + 1/j^7$

   (k) $\overline{b\quad a}\ \overline{a\quad b}$ (l) $\frac{\overline{\quad 3}\ \overline{12}}{j\quad \overline{\quad a^2}}$

4. Determine the imaginary part of z:

   (a) $z = 3 + 7j$

   (b) $z = 15j \quad 4$

5. Determine the conjugate complex number z of z:

   (a) $z = 5 + 2j$

   (b) $z = \frac{1}{2} \qquad \overline{3}j$

6. Evaluate the (complex) roots of the following quadratic equations:

   (a) $x^2 + 4x + 13 = 0$

   (b) $x^2 + \frac{3}{2}x + \frac{25}{16} = 0$

7. Calculate the sum $z_1 + z_2$:

   (a) $z_1 = 3 \quad 2j$ (b) $z_1 = \frac{3}{4} + \frac{3}{4}j$

   $z_2 = 7 + 5j$ $z_2 = \frac{3}{4} \quad \frac{3}{4}j$

8. Compute $w = z_1 \quad z_2 + z_3$:

   (a) $z_1 = 5 \quad 2j$
   $z_2 = 2 \quad 3j$
   $z_3 = \quad 4 + 6j$

   (b) $z_1 = 4 \quad 3.5j$
   $z_2 = 3 + 2j$
   $z_3 = 7.5j$

9. Compute the product $w = z_1 z_2$:

   (a) $z_1 = 1 + j$
   $z_2 = 1 \quad j$

   (b) $z_1 = 3 \quad 2j$
   $z_2 = 5 + 4j$

10. Determine

   (a) $(16 + j \quad \overline{2})/2 \quad \overline{2}$

   (b) $(4 \quad j \quad \overline{3})/2j$

   (c) $(2 + 3j)/(2 \quad 4j)$

   (d) $1/(1 + j)$

   (e) $\dfrac{1 + j}{1 \quad j} \quad \dfrac{1 \quad j}{1 + j}$

   (f) $\dfrac{(5 + j \quad \overline{3})(5 \quad j \quad \overline{3})}{2 \quad j \quad \overline{3}}$

11. Convert the following sums into products:

   (a) $4x^2 + 9y^2$

   (b) $a + b$

9.2 Graphical Representation of Complex Numbers

12. Plot each point z_i and $\quad z_i$ in the complex number plane:

   (a) $z_1 = \quad 1 \quad j$

   (b) $z_2 = 3 + 2j$

   (c) $z_3 = 5 + 3j$

   (d) $z_4 = \dfrac{3}{2}j$

   (e) $z_5 = \quad 3 + \dfrac{1}{2}j$

   (f) $z_6 = \quad \overline{2}$

13. Using Fig. 9.16, determine the real and imaginary parts of each point $z_1, z_2, \cdots, z_6$.

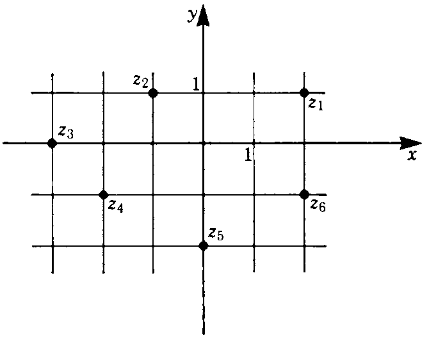

Fig. 9.16

14. Convert the complex number $z = x + jy$ to the polar form $z = r(\cos\ \ + j\sin\ \ )$:

(a) $z = j\ \ 1$

(b) $z = \ \ (1 + j)$

15. Transform the complex number $z = r(\cos\ \ + j\sin\ \ )$ into the form $z = x + jy$:

(a) $z = 5\ \ \cos\frac{\ }{3}\ \ \ j\sin\frac{\ }{3}$

(b) $z = 4(\cos 225\ \ + j\sin 225\ \ )$

16. Compute $z_1 z_2$:

(a) $z_1 = 2(\cos 15\ \ + j\sin 15\ \ )$
$z_2 = 3(\cos 45\ \ + j\sin 45\ \ )$

(b) $z_1 = \ \ \overline{5}(\cos 80\ \ + j\sin 80\ \ )$
$z_2 = \ \ \overline{5}(\cos 40\ \ + j\sin 40\ \ )$

17. Calculate z_1/z_2:

(a) $z_1 = \cos 70\ \ + j\sin 70$
$z_2 = \cos 25\ \ + j\sin 25$

(b) $z_1 = 4$
$z_2 = 4(\cos 30\ \ + j\sin 30\ \ )$
(*Hint:* $4 = 4(\cos 360\ \ + j\sin 360\ \ )$)

18. What is meant geometrically by the multiplication (or division) of a complex number by $\ \ j$?

19. Calculate

(a) $(1\ \ \ j)^5$

(b) $\frac{1}{2}\ \ \ j\frac{1}{2}\ \ \overline{3}\ \ ^{3}$

20. (a) Prove that $(\cos 50\ \ \ \ j\sin 50\ \ )^4 = \cos 200\ \ \ \ j\sin 200\ \ $.
(b) State De Moivre s theorem.

21. Calculate all the roots of

(a) $\overline{\ \ \ 5 + 12j}$

(b) $^4\overline{\cos 60\ \ + j\sin 60\ \ }$

9.3 Exponential Form of Complex Numbers

22. Using Euler s formula, compute cos and sin and convert to the algebraic form:

(a) $e^{j\ \ /2}$

(b) $e^{j\ \ /3}$

23. Let the values for e^{j} and $e^{\ \ j}$ be given. Compute the values of , cos and sin :

(a) $e^{j} = 1$
$e^{\ \ j} = 1$

(b) $e^{j} = \ \ 1$
$e^{\ \ j} = \ \ 1$

(c) $e^{j} = \ \ j$
$e^{\ \ j} = j$

(d) $e^{j} = \frac{1}{2}\ \ \overline{3} + \frac{j}{2}$
$e^{\ \ j} = \frac{1}{2}\ \ \overline{3}\ \ \ \frac{j}{2}$

24. Given the complex number $z = x + jy, w = e^{z}$ is then a new complex number. Put it in the form $w = re^{j}$ and compute r and if

(a) $z = 3 + 2j$ (b) $z = 2 \quad \frac{j}{2}$

25. Transform the complex number $w = e^{z}$ into the form $w = u + jv$ if

(a) $z = \frac{1}{2} + j$ (b) $z = \frac{3}{2} \quad j$

(c) $z = \quad 1 \quad j\frac{3}{2}$ (d) $z = 3 \quad j$

26. Let the complex quantity z be a linear function of the parameter t (for example time), i.e. $z(t) = at + jbt(0 \quad t \quad d)$. Given

(a) $z(t) = \quad t + j2 \quad t$,

(b) $z(t) = 2t \quad j\frac{3}{2}t$,

(i) what is the real part, Re[$w(t)$], of $w(t) = e^{z(t)}$?
(ii) what is the period of Re[$w(t)$]?
(iii) what is the amplitude of the function $w(t)$ at time $t = 2$?

27. Compute the product $z_1 z_2$:

(a) $z_1 = 2e^{j \quad /2}$ (b) $z_1 = \frac{1}{2}e^{j \quad /4}$

$z_2 = \frac{1}{2}e^{j \quad /2}$ $z_2 = \frac{3}{2}e^{\quad j3 \quad /4}$

28. Calculate for the pairs of numbers z_1, z_2 in the previous exercise the quotient $z_1 \quad / z_2$.

29. (a) Given $z = 2e^{j \quad /5}$, calculate z^{5}.
(b) Given $z = \frac{1}{2}e^{j \quad /4}$, calculate z^{3}.

30. (a) Given $z = 32e^{j10}$, calculate $z^{1/5}$.
(b) Given $z = \frac{1}{16}e^{j6}$, calculate $z^{1/4}$.

31. Given $z = re^{j}$, what in each of the following cases is the angle for which $0 \quad 2$?

(a) $z = 3e^{j7}$ (b) $z = \frac{1}{2}e^{j14 \quad /3}$

32. Put the following complex numbers into exponential form:

(a) $5 \quad 5j$ (b) $15 \quad 13j$

33. (a) Put the expression $z = 2.5e^{j43 \quad 30}$ into the form $x + jy$.
(b) Calculate $e^{j146} \quad e^{\quad j82}$ and express the result in the form $z = x + jy$.

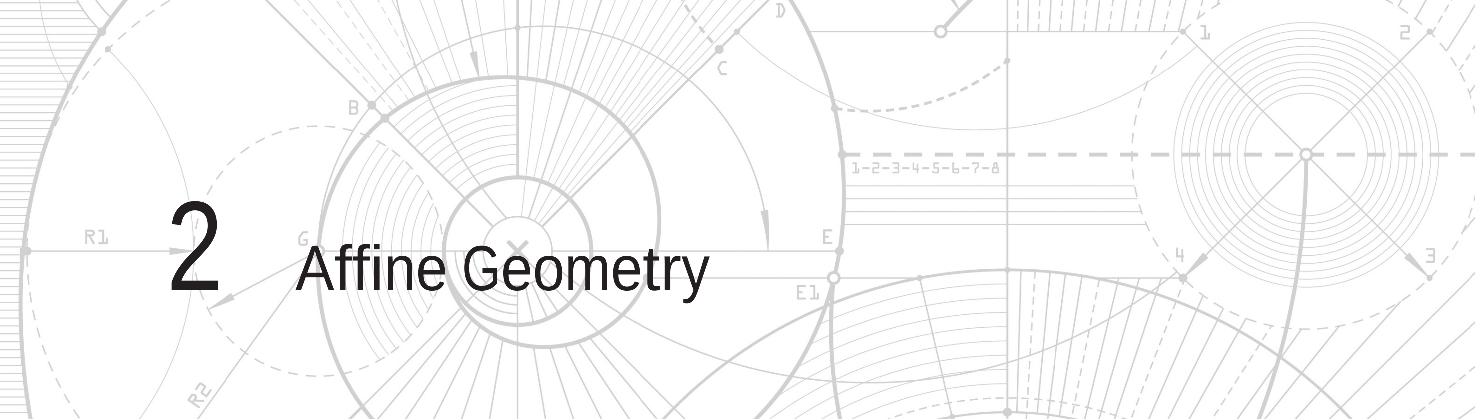
9.4 Operations with Complex Numbers Expressed in Polar Form

34. (a) Determine the real and imaginary parts of $\dfrac{(1 + j)^2}{\overline{2}(1 \quad j)}$

    (b) What is the polar form of this complex number?

35. Put $z = \quad 2(\cos 30 \quad j \sin 30\ )$:

    (a) into the form $x + jy$,
    (b) into exponential form.



2 Affine Geometry

In Chapter 1 we studied conics in Euclidean geometry. In the rest of the book we prove a whole range of results about figures such as lines and conics, in geometries other than Euclidean geometry. In the process of doing this, we meet two particular features of our approach to geometry which may be new to you.

The first feature is the use of transformations in geometry to simplify problems and bring out their essential character. You may have met some of these transformations previously in courses on Group Theory or on Linear Algebra.

In this book, we shall often use matrices to simplify our work.

The second feature arises from the fact that the transformations we introduce form groups. Generally, we restrict our attention to geometry in the plane, $\mathbb{R}^2$, but even in this familiar setting there may be more than one group of transformations at our disposal. This leads to the exciting new idea that there are many different geometries!

Each geometry consists of a space, some properties possessed by figures in that space, and a group of transformations of the space that preserve these properties. For example, Euclidean plane geometry uses the space $\mathbb{R}^2$, and is concerned with those properties of figures that depend on the notion of distance. The group associated with Euclidean geometry is the group of isometries of the plane.

This is because isometries of the plane preserve distances.

This idea, that geometry can be thought of in terms of a space and a group acting on it, is called the *Kleinian view of geometry*, after the 19th-century German mathematician Felix Klein who proposed it first. It has the virtue of enabling us to generate many geometries, while seeing how they are related.

For instance, we can take $\mathbb{R}^2$ as our space and use the group of all transformations of the form $t(\mathbf{x}) = \mathbf{A}\mathbf{x} + \mathbf{a}$, where $\mathbf{a} \in \mathbb{R}^2$ and $\mathbf{A}$ is a 2×2 invertible matrix. These are the so-called *affine transformations* of $\mathbb{R}^2$. But what properties of figures in $\mathbb{R}^2$ are preserved by such transformations, and what is the corresponding geometry? The geometry is called *affine geometry*, and it is the subject of this chapter. As you will see, it has some features in common with Euclidean geometry, but also some very different features.

In Section 2.1 we examine Euclidean geometry from the Kleinian point of view, and explain why geometries other than Euclidean geometry exist.

In Sections 2.2 and 2.3 we introduce affine geometry and consider its properties. In particular, we show that affine transformations map straight lines to straight lines, map parallel lines to parallel lines, and preserve ratios of lengths along a given line. We also discover that in affine geometry all triangles are congruent, in the sense that any triangle can be mapped onto any other triangle by an affine transformation. This result is known as the *Fundamental Theorem of Affine Geometry*.

In Section 2.4 we establish two important theorems, due to Ceva and Menelaus, which involve ratios of lengths along the sides of a triangle.

Finally, in Section 2.5 we investigate the effect of affine transformations on conics, and discover that we can use the methods of affine geometry to obtain very simple proofs of certain types of theorems about conics.

2.1 Geometry and Transformations

Before embarking on a study of various other geometries, it is useful first to look back at our familiar Euclidean geometry.

2.1.1 What is Euclidean Geometry?

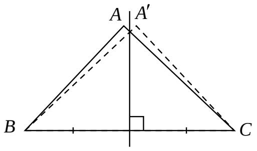
To help us answer this question, we begin by considering the following well-known result.

Example 1 Let $\triangle ABC$ be a triangle in which $\angle ABC = \angle ACB$. Prove that $AB = AC$.

Solution First, reflect the triangle in the perpendicular bisector of BC, so that the points B and C change places and the point A moves to some point A', say. Since reflection preserves angles, it follows that $\angle A'BC = \angle ACB$.

Also, we are given that $\angle ACB = \angle ABC$, so

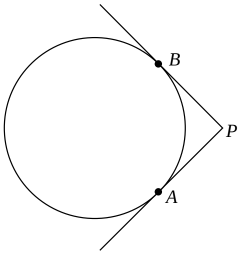
$$\angle A'BC = \angle ABC.$$



But this can happen only if A' lies on the line through A and B. Similarly,

$$\angle A'CB = \angle ABC = \angle ACB,$$

so A' must also lie on the line through A and C. This means that A and A' must coincide. Hence the line segment AB reflects to the line segment AC, and vice versa. Since reflection preserves lengths, it follows that $AB = AC$. □



Problem 1 Let A and B be two points on a circle, and let the tangents to the circle at A and B meet at P. Prove that $AP = BP$.

Hint: Consider a reflection in the line which passes through P and the centre of the circle.

The result in Example 1 is concerned with the properties of length and angle associated with the triangle ABC. To investigate these properties, we introduced a reflection that enabled us to compare various lengths and angles. We were able to do this because reflections leave lengths and angles unchanged.

Of course, reflections are not the only transformations that preserve lengths and angles: other examples include rotations and translations. In general, any transformation that preserves lengths and angles can be used to tackle problems which involve these properties. In fact, we need worry only about leaving distances unchanged, since any transformation from $\mathbb{R}^2$ onto $\mathbb{R}^2$ that changes angles must also change lengths. Transformations that leave distances unchanged are called *isometries.*

This is because, once we know the lengths of the sides of a triangle, the angles are uniquely determined.

Definition An **isometry** of $\mathbb{R}^2$ is a function which maps $\mathbb{R}^2$ onto $\mathbb{R}^2$ and preserves distances.

In fact, every isometry has one of the following forms:

a translation along a line in $\mathbb{R}^2$;
a reflection in a line in $\mathbb{R}^2$;
a rotation about a point in $\mathbb{R}^2$;
a composite of translations, reflections and rotations in $\mathbb{R}^2$.

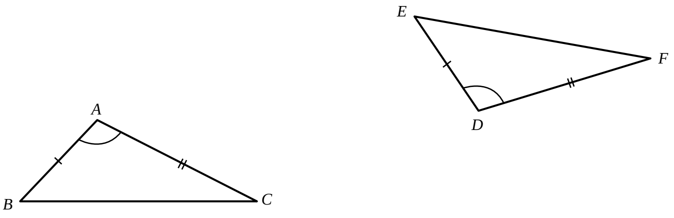
The identity isometry can be regarded as a rotation through an angle that is a multiple of 2 .

The composite of any two isometries is also an isometry, and so it is easy to verify that the set $S(\mathbb{R}^2)$ of isometries of $\mathbb{R}^2$ forms a group under composition of functions. These observations can be used to build up the transformations we need in order to prove Euclidean results.

Example 2 Prove that if ABC and DEF are two triangles such that

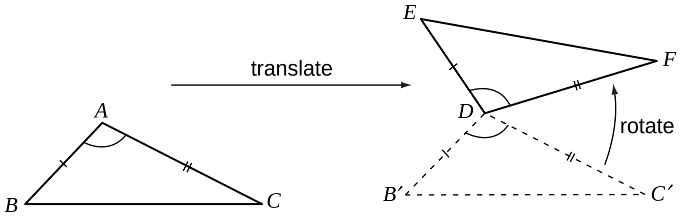
$$AB = DE, \quad AC = DF \quad \text{and} \quad BAC = EDF,$$

then $BC = EF$, $ABC = DEF$ and $ACB = DFE$.



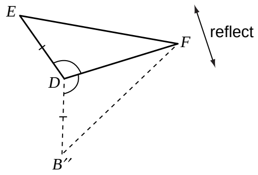
Solution It is sufficient to show that there is an isometry which maps ABC onto DEF. We construct this isometry in stages, starting with the translation which maps A to D. This translation maps $\triangle ABC$ onto $\triangle DB'C'$, where B' and C' are the images of B and C under the translation.

Of course, A and D may already coincide, in which case we omit the translation stage.



Since we are given that $DF = AC$, and since the translation maps AC onto DC', it follows that $DF = DC'$. We can therefore rotate the point C', about D, until it coincides with the point F. This rotation maps $\triangle DB'C'$ onto $\triangle DB''F$, as shown in the margin, where B'' is the image of B' under the rotation.

If C' already coincides with F, then we omit the rotation stage.



Finally, notice that

$$\begin{aligned} \angle FDE &= \angle CAB && \text{(given)} \\ &= \angle C'DB' && \text{(translation)} \\ &= \angle FDB'' && \text{(rotation)}, \end{aligned}$$

so either B'' lies on DE or the reflection of B'' in the line FD lies on DE. Also

$$\begin{aligned} DE &= AB && \text{(given)} \\ &= DB' && \text{(translation)} \\ &= DB'' && \text{(rotation)}. \end{aligned}$$

It follows that either B'' coincides with E or the reflection of B'' in the line FD coincides with E.

So, composing the translation, the rotation, and (if necessary) a reflection, we obtain the required isometry that maps $\triangle ABC$ onto $\triangle DEF$. Since isometries preserve length and angle, it follows that $BC = EF$, $\angle ABC = \angle DEF$ and $\angle ACB = \angle DFE$. □

Problem 2 Prove that if $\triangle ABC$ and $\triangle DEF$ are two triangles such that

$$AC = DF, \quad \angle BAC = \angle EDF \quad \text{and} \quad \angle ACB = \angle DFE,$$

then $BC = EF$, $AB = DE$ and $\angle ABC = \angle DEF$.

We can now answer the question 'What is Euclidean geometry?'. **Euclidean geometry** is the study of those properties of figures that are unchanged by the group of isometries. We call these properties **Euclidean properties**. Roughly speaking, a Euclidean property is one that is preserved by a rigid figure as it moves around the plane. Of course, these properties include distance and angle, but they also include other properties such as collinearity of points and concurrence of lines.

We consider only Euclidean geometry in the plane $\mathbb{R}^2$.

This idea, that geometry can be thought of in terms of a group of transformations acting on a space, is known as the *Kleinian view of geometry*. It enables us to generate many geometries, without losing sight of the relationship between them.

Here a space is simply a collection of points; for example, the plane is $\mathsf{R}^2 = \{(x, y) : x, y \text{ are real}\}$.

When we consider geometries in this way, it is often convenient to have an algebraic representation for the transformations involved. This not only enables us to solve problems in the geometry algebraically, but also provides us with formulas that can be used to compare different geometries.

In the case of Euclidean geometry, perhaps the easiest way to represent isometries algebraically is to use matrices. For example, the function defined by

$$t : \begin{matrix} x \\ y \end{matrix} \qquad \begin{matrix} \cos & \sin \\ \sin & \cos \end{matrix} \quad \begin{matrix} x \\ y \end{matrix} + \begin{matrix} e \\ f \end{matrix} \qquad (x, y) \quad \mathsf{R}^2 \tag{1}$$

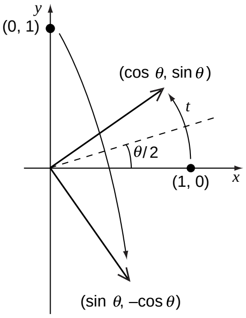
is an isometry because it is the composite of an anticlockwise rotation through an angle about the origin, followed by a translation through the vector (e, f).

Similarly, the function

$$t : \begin{matrix} x \\ y \end{matrix} \qquad \begin{matrix} \cos & \sin \\ \sin & \cos \end{matrix} \quad \begin{matrix} x \\ y \end{matrix} + \begin{matrix} e \\ f \end{matrix} \qquad (x, y) \quad \mathsf{R}^2 \tag{2}$$

is an isometry because it is the composite of a reflection in the line through the origin that makes an angle $/2$ with the x-axis, followed by a translation through the vector (e, f).

Recall that the effect of the matrix multiplication in (1) and (2) can be interpreted geometrically by examining what happens to the vectors (1, 0) and (0, 1). For example, in (2) the matrix multiplication sends (1, 0) and (0, 1) to (cos , sin) and (sin , cos), respectively, so it corresponds to the reflection shown in the figure below.



Remarkably, we can represent *any* isometry by one or other of the forms given in (1) and (2). To see this, notice that any isometry t can be written in the form

$$t(\mathbf{x}) = t_0(\mathbf{x}) + (e, f) \qquad \mathbf{x} \quad \mathsf{R}^2 , \tag{3}$$

where t_0 is an isometry which fixes the origin. Indeed, if we let $(e, f) = t(\mathbf{0})$, then we can let t_0 be the transformation defined by $t_0(\mathbf{x}) = t(\mathbf{x}) \quad (e, f)$. This is an isometry because it is the composite of the isometry t and the translation through the vector $\quad (e, f)$. It fixes the origin since $t_0(\mathbf{0}) = t(\mathbf{0}) \quad (e, f) = \mathbf{0}$.

Now an isometry that fixes the origin must be either a rotation about the origin, or a reflection in a line through the origin. If t_0 is a rotation about the origin, then (3) can be written in the matrix form given in (1), whereas if t_0 is a reflection in a line through the origin, then (3) can be written in the matrix form given in (2).

So together, equations (1) and (2) provide us with an algebraic representation of all possible isometries of the plane. The next problem indicates how we can obtain a more concise description of this algebraic representation by using orthogonal matrices to combine equations (1) and (2).

Recall that a matrix $\mathbf{U}$ is *orthogonal* if $\mathbf{U}^{\ 1} = \mathbf{U}^T$, that is, if $\mathbf{U}^T\mathbf{U} = \mathbf{I}$. This is equivalent to saying that the columns of $\mathbf{U}$ are *orthonormal*.

Problem 3 Show that both the matrices

$$\begin{matrix} \cos & \sin \\ \sin & \cos \end{matrix} \quad \text{and} \quad \begin{matrix} \cos & \sin \\ \sin & \cos \end{matrix} ,$$

which appear in (1) and (2), are orthogonal for each real number .

By applying the solution of Problem 3 to equations (1) and (2), we see that every isometry t has an algebraic representation of the form

$$t(\mathbf{x}) = \mathbf{U}\mathbf{x} + \mathbf{a},$$

where $\mathbf{U}$ is an orthogonal 2×2 matrix, and $\mathbf{a}$ is a vector in R^2.

This equation shows the matrix $\mathbf{U}$ acting on the vector $\mathbf{x} = (x, y)$. Strictly speaking, $\mathbf{U}$ acts on the coordinates $\begin{matrix} x \\ y \end{matrix}$ of $\mathbf{x}$ with respect to the standard basis of the vector space R^2 as in equations (1) and (2). However, since the numbers x and y are the same for the vector and its standard coordinates, no confusion should arise.

Definition A **Euclidean transformation** of R^2 is a function $t : \mathrm{R}^2 \quad \mathrm{R}^2$ of the form

$$t(\mathbf{x}) = \mathbf{U}\mathbf{x} + \mathbf{a},$$

where $\mathbf{U}$ is an orthogonal 2×2 matrix and $\mathbf{a} \quad \mathrm{R}^2$. The set of all Euclidean transformations of R^2 is denoted by $E(2)$.

We may summarize the discussion above by saying that every isometry of the plane is a Euclidean transformation of R^2.

In fact, the converse is also true, for if $\mathbf{U}$ is any orthogonal matrix, then its columns are orthonormal. In particular, its first and second columns have unit length and can therefore be written in the form $\begin{matrix} \cos \\ \sin \end{matrix}$ and $\begin{matrix} \cos \\ \sin \end{matrix}$, respectively, for some real $\ ,\ $. For these to be orthonormal, we must have $\cos \ \bullet \cos \ + \sin \ \bullet \sin \ = 0$, so that $\tan \ \bullet \tan \ = \ 1$ and hence $\ = \ - \frac{}{2}$. It follows that the second column must be

$$\begin{matrix} \cos(\ + \ /2) \\ \sin(\ + \ /2) \end{matrix} = \begin{matrix} \sin \\ \cos \end{matrix} \quad \text{or}$$

$$\begin{matrix} \cos(\quad /2) \\ \sin(\quad /2) \end{matrix} = \begin{matrix} \sin \\ \cos \end{matrix}.$$

So

$$\mathbf{U} = \begin{matrix} \cos & \sin \\ \sin & \cos \end{matrix} \quad \text{or} \quad \mathbf{U} = \begin{matrix} \cos & \sin \\ \sin & \cos \end{matrix}.$$

It follows that every Euclidean transformation $t(\mathbf{x}) = \mathbf{U}\mathbf{x} + \mathbf{a}$ of R^2 has one of the forms given in equations (1) and (2). Since both of these forms represent isometries of the plane,we have the following theorem.

Theorem 1 Every isometry of R^2 is a Euclidean transformation of R^2, and vice versa.

Now the set of all isometries of R^2 forms a group under composition of functions, so it follows from Theorem 1 that the same must be true of the set of all Euclidean transformations of R^2. We therefore have the following theorem.

It is not difficult to prove that this is a group, so we omit the proof.

Theorem 2 The set of Euclidean transformations of R^2 forms a group under the operation of composition of functions.

It is instructive to check the group axioms algebraically, for in the process of doing so we obtain formulas for the composites and inverses of Euclidean transformations.

We start by considering closure. Suppose that t_1 and t_2 are two Euclidean transformations given by

$$t_1(\mathbf{x}) = \mathbf{U}_1\mathbf{x} + \mathbf{a}_1 \quad \text{and} \quad t_2(\mathbf{x}) = \mathbf{U}_2\mathbf{x} + \mathbf{a}_2,$$

where $\mathbf{U}_1$ and $\mathbf{U}_2$ are orthogonal 2 × 2 matrices. Then the composite $t_1 \quad t_2$ is given by

$$\begin{aligned} t_1 \quad t_2(\mathbf{x}) &= t_1(\mathbf{U}_2\mathbf{x} + \mathbf{a}_2) \\ &= \mathbf{U}_1(\mathbf{U}_2\mathbf{x} + \mathbf{a}_2) + \mathbf{a}_1 \\ &= \mathbf{U}_1\mathbf{U}_2\mathbf{x} + (\mathbf{U}_1\mathbf{a}_2 + \mathbf{a}_1). \end{aligned}$$

This is a Euclidean transformation since $\mathbf{U}_1\mathbf{U}_2$ is orthogonal. Indeed,

$$(\mathbf{U}_1\mathbf{U}_2)^T = \mathbf{U}_2^T\mathbf{U}_1^T = \mathbf{U}_2^{\ 1}\mathbf{U}_1^{\ 1} = (\mathbf{U}_1\mathbf{U}_2)^{\ 1}.$$

Here we are using the result that $(\mathbf{AB})^T = \mathbf{B}^T\mathbf{A}^T$.

So the set of Euclidean transformations is closed under composition of functions.

Problem 4 Let the Euclidean transformations t_1 and t_2 of $\mathbb{R}^2$ be given by

$$t_1(\mathbf{x}) = \begin{matrix} \frac{3}{5} & \frac{4}{5} \\ \frac{4}{5} & \frac{3}{5} \end{matrix} \ \mathbf{x} + \begin{matrix} 1 \\ 2 \end{matrix}$$

and

$$t_2(\mathbf{x}) = \begin{matrix} \frac{4}{5} & \frac{3}{5} \\ \frac{3}{5} & \frac{4}{5} \end{matrix} \ \mathbf{x} + \begin{matrix} 2 \\ 1 \end{matrix} \ .$$

Determine $t_1 \quad t_2$ and $t_2 \quad t_1$.

Next recall that under composition of functions the identity is the transformation given by $i(\mathbf{x}) = \mathbf{x}$. This is a Euclidean transformation since it can be written in the form

$$i(\mathbf{x}) = \mathbf{I}\mathbf{x} + \mathbf{0},$$

where $\mathbf{I}$ is the 2 × 2 identity matrix, which is orthogonal.

The next problem asks you to show that inverses exist.

Problem 5 Prove that if t_1 is a Euclidean transformation of $\mathbb{R}^2$ given by

$$t_1(\mathbf{x}) = \mathbf{U}\mathbf{x} + \mathbf{a} \qquad (\mathbf{x} \quad \mathbb{R}^2),$$

then:

(a) the transformation of $\mathbb{R}^2$ given by

$$t_2(\mathbf{x}) = \mathbf{U}^{-1}\mathbf{x} - \mathbf{U}^{-1}\mathbf{a} \qquad (\mathbf{x} \in \mathbb{R}^2)$$

is also a Euclidean transformation;

(b) the transformation t_2 is the inverse of t_1.

The solution of Problem 5 shows that we can calculate the inverse of a Euclidean transformation by using the following result.

> The inverse of the Euclidean transformation $t(\mathbf{x}) = \mathbf{U}\mathbf{x} + \mathbf{a}$ is given by
>
> $$t^{-1}(\mathbf{x}) = \mathbf{U}^{-1}\mathbf{x} - \mathbf{U}^{-1}\mathbf{a}.$$

Problem 6 Determine the inverse of the Euclidean transformation given by

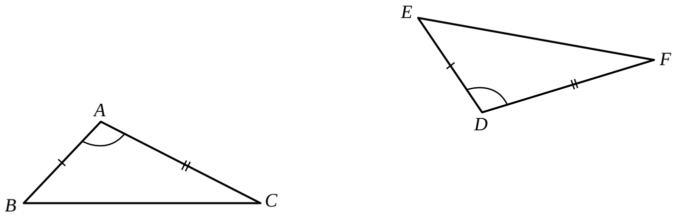
$$t(\mathbf{x}) = \begin{pmatrix} \frac{3}{5} & \frac{4}{5} \\ \frac{4}{5} & \frac{3}{5} \end{pmatrix} \mathbf{x} + \begin{pmatrix} 1 \\ 2 \end{pmatrix}.$$

Finally, composition of functions is always associative. So all four group properties hold, as we expected.

Earlier, we described Euclidean geometry as the study of those properties of figures that are preserved by isometries. Having identified these isometries with the group of Euclidean transformations, we can now give the equivalent algebraic description of Euclidean geometry. **Euclidean geometry** is the study of those properties of figures that are preserved by Euclidean transformations of $\mathbb{R}^2$.

2.1.2 Euclidean-Congruence

In the solution to Example 2 we showed that if two triangles $\triangle ABC$ and $\triangle DEF$ are such that $AB = DE$, $AC = DF$ and $\angle BAC = \angle EDF$, then there is a Euclidean transformation which maps $\triangle ABC$ onto $\triangle DEF$.



The existence of this transformation enabled us to deduce that both triangles have the same Euclidean properties. In particular, we were able to deduce that $BC = EF$, $\angle ABC = \angle DEF$ and $\angle ACB = \angle DFE$.

In order to formalize this way of relating two figures, we say that two figures are *congruent* if one can be moved to fill exactly the position of the other by means of a Euclidean transformation. Loosely speaking, two figures are congruent if they have the same size and shape.

Later we consider congruence with respect to other groups of transformations (that is, congruence in other geometries), so if there is any danger of confusion we sometimes say that two figures are *Euclidean-congruent*.

Definition A figure F_1 is **Euclidean-congruent** to a figure F_2 if there is a Euclidean transformation which maps F_1 onto F_2.

For example, any two circles of unit radius are Euclidean-congruent to each other because we can map one of the circles onto the other by means of a translation that makes their centres coincide.

Of course, there are many other Euclidean transformations which map one of the circles onto the other.

Problem 7 Which of the following sets consist of figures that are Euclidean-congruent to each other?

(a) The set of all ellipses
(b) The set of all line segments of length 1
(c) The set of all triangles
(d) The set of all squares that have sides of length 2

Earlier, we emphasized that the Euclidean transformations form a group. This is important because it ensures that Euclidean-congruence has the kind of properties that we should expect. For example, we should expect every figure to be congruent to itself. Also, if a figure F_1 is congruent to a figure F_2, then we should expect F_2 to be congruent to F_1. We can, in fact, establish the following result.

Theorem 3 Euclidean-congruence is an equivalence relation.

Proof We show that the three equivalence relation axioms E1, E2 and E3 hold.

E1 REFLEXIVE For all figures F in $\mathbb{R}^2$, the identity transformation maps F onto itself; so Euclidean-congruence is reflexive.

This uses the existence of an *identity* transformation.

E2 SYMMETRIC Let a figure F_1 in $\mathbb{R}^2$ be congruent to a figure F_2, and let t be a Euclidean transformation which maps F_1 onto F_2. Then the inverse Euclidean transformation t^{-1} maps F_2 onto F_1, so that F_2 is congruent to F_1. Thus Euclidean-congruence is symmetric.

This uses the existence of *inverse* transformations.

E3 TRANSITIVE Let a figure F_1 in $\mathbb{R}^2$ be congruent to a figure F_2, and let F_2 be congruent to a figure F_3. Then there exist Euclidean transformations t_1 mapping F_1 onto F_2 and t_2 mapping F_2 onto F_3. Thus the Euclidean transformation $t_2 \circ t_1$ maps F_1 onto F_3, so that F_1 is congruent to F_3. Hence Euclidean-congruence is transitive.

This uses the closure axiom for the group of Euclidean transformations.

It follows that Euclidean-congruence is an equivalence relation, because it satisfies the axioms El, E2 and E3.

Problem 8 Prove that if two figures in $\mathbb{R}^2$ are each Euclidean-congruent to a third figure, then they are Euclidean-congruent to each other.

Since Euclidean-congruence is an equivalence relation, it partitions the set of all figures into disjoint equivalence classes. Each class consists of figures which are Euclidean-congruent to each other, and hence share the same Euclidean properties (for example, one class consists of all circles of unit radius, another class consists of all equilateral triangles with sides of length 3, and so on). If we wish to show that two figures have the same Euclidean properties, then it is sufficient to show that they are Euclidean-congruent.

For example, to show that two triangles $\triangle ABC$ and $\triangle DEF$ have the same Euclidean properties, it is sufficient to show that $AB = DE$, $AC = DF$ and $\angle BAC = \angle EDF$, as you saw in Example 2. This congruence condition is frequently used in Euclidean geometry. It is known as the 'side angle side' (SAS) condition for congruence.

Now Euclidean geometry is just one of several different geometries. Each geometry is defined by a group G of transformations that act on a space. In general, we say that two figures are ***G*-congruent** if there is a transformation in G which maps one of the figures onto the other. Since the only properties used in the proof of Theorem 3 are the group properties of Euclidean transformations, the theorem holds also with 'G-congruent' in place of 'Euclidean-congruent'. Thus, like Euclidean-congruence, G-congruence is an equivalence relation that partitions the set of all figures into disjoint equivalence classes.

This idea of partitioning figures into equivalence classes is central to geometry. It enables us to distinguish between figures in different equivalence classes, without having to worry about the differences between figures in the same equivalence class. For example, if we are interested in whether a conic is an ellipse rather than a hyperbola or a parabola, but do not care about its shape (that is, the ratio of the lengths of its axes), we might choose to work with some geometry whose group of transformations makes all ellipses congruent to each other — but not congruent to any hyperbola or parabola. We describe a group of transformations which defines such a geometry in Section 2.2.

2.2 Affine Transformations and Parallel Projections

2.2.1 Affine Transformations

In Section 2.1 you met a new approach to Euclidean geometry in $\mathbb{R}^2$ — namely, the idea that Euclidean geometry of $\mathbb{R}^2$ can be interpreted as a space, $\mathbb{R}^2$, together with the group of Euclidean transformations which act on that space. Recall that a Euclidean transformation is a function $t : \mathbb{R}^2 \to \mathbb{R}^2$ of the form

$$t(\mathbf{x}) = \mathbf{Ux} + \mathbf{a} \quad (\mathbf{x} \in \mathbb{R}^2),$$

where $\mathbf{U}$ is an orthogonal 2×2 matrix. Euclidean properties of figures are those, like distance and angle, that are preserved by these transformations.

In this section we meet the first of our new geometries in $\mathbb{R}^2$ — *affine geometry*. This geometry consists of the space $\mathbb{R}^2$ together with a group of transformations, the *affine transformations*, acting on $\mathbb{R}^2$.

Affine geometry can be defined in $\mathbb{R}^n$, for any $n \geq 2$; we restrict our attention here to the case when $n = 2$.

Definition An **affine transformation** of $\mathbb{R}^2$ is a function $t : \mathbb{R}^2 \to \mathbb{R}^2$ of the form

$$t(\mathbf{x}) = \mathbf{Ax} + \mathbf{b},$$

where $\mathbf{A}$ is an invertible 2×2 matrix and $\mathbf{b} \in \mathbb{R}^2$. The set of all affine transformations of $\mathbb{R}^2$ is denoted by $A(2)$.

Remark

Note that every Euclidean transformation of $\mathbb{R}^2$ is an affine transformation of $\mathbb{R}^2$ since every orthogonal matrix is invertible. (In terms of groups, the group of Euclidean transformations of $\mathbb{R}^2$ is a proper subgroup of the group of affine transformations of $\mathbb{R}^2$.) This means that all properties of figures that are preserved by affine transformations must be preserved also by Euclidean transformations.

Problem 1 Determine whether or not each of the following transformations of $\mathbb{R}^2$ is an affine transformation.

(a) $t_1(\mathbf{x}) = \begin{pmatrix} 1 & 3 \\ 1 & 2 \end{pmatrix} \mathbf{x} + \begin{pmatrix} 4 \\ 2 \end{pmatrix}$ (b) $t_2(\mathbf{x}) = \begin{pmatrix} 6 & 5 \\ 3 & 2 \end{pmatrix} \mathbf{x} + \begin{pmatrix} 2 \\ 1 \end{pmatrix}$

(c) $t_3(\mathbf{x}) = \begin{pmatrix} 2 & 1 \\ 8 & 4 \end{pmatrix} \mathbf{x} + \begin{pmatrix} 1 \\ 3 \end{pmatrix}$ (d) $t_4(\mathbf{x}) = \begin{pmatrix} 5 & 3 \\ 2 & 2 \end{pmatrix} \mathbf{x}$

The algebra required to compose affine transformations is similar to the algebra that we used to compose Euclidean transformations.

Problem 2 For the transformations of $\mathbb{R}^2$ given in Problem 1, determine formulas for the following composites. In each case, state whether or not the composite is an affine transformation.

(a) $t_1 \circ t_2$ (b) $t_2 \circ t_4$

We now verify our assertion above that the set of affine transformations forms a group.

Theorem 1 The set of affine transformations $A(2)$ forms a group under the operation of composition of functions.

Proof We check that the four group axioms hold.

G1 CLOSURE Let t_1 and t_2 be affine transformations given by

$$t_1(\mathbf{x}) = \mathbf{A}_1\mathbf{x} + \mathbf{b}_1 \quad \text{and} \quad t_2(\mathbf{x}) = \mathbf{A}_2\mathbf{x} + \mathbf{b}_2,$$

where $\mathbf{A}_1$ and $\mathbf{A}_2$ are invertible 2 × 2 matrices. Then, for each $\mathbf{x} \in \mathbb{R}^2$,

$$\begin{aligned}(t_1 \circ t_2)(\mathbf{x}) &= t_1(\mathbf{A}_2\mathbf{x} + \mathbf{b}_2)\\ &= \mathbf{A}_1(\mathbf{A}_2\mathbf{x} + \mathbf{b}_2) + \mathbf{b}_1\\ &= (\mathbf{A}_1\mathbf{A}_2)\mathbf{x} + (\mathbf{A}_1\mathbf{b}_2 + \mathbf{b}_1).\end{aligned}$$

Since $\mathbf{A}_1$ and $\mathbf{A}_2$ are invertible, it follows that $\mathbf{A}_1\mathbf{A}_2$ is also invertible. So by definition $t_1 \circ t_2$ is an affine transformation.

G2 IDENTITY Let i be the affine transformation given by

$$i(\mathbf{x}) = \mathbf{I}\mathbf{x} + \mathbf{0} \quad (\mathbf{x} \in \mathbb{R}^2),$$

where $\mathbf{I}$ is the 2 × 2 identity matrix. If t is an affine transformation given by

$$t(\mathbf{x}) = \mathbf{A}\mathbf{x} + \mathbf{b} \quad (\mathbf{x} \in \mathbb{R}^2),$$

then, for each $\mathbf{x} \in \mathbb{R}^2$,

$$(t \circ i)(\mathbf{x}) = \mathbf{A}(\mathbf{I}\mathbf{x} + \mathbf{0}) + \mathbf{b} = \mathbf{A}\mathbf{x} + \mathbf{b} = t(\mathbf{x})$$

and

$$(i \circ t)(\mathbf{x}) = \mathbf{I}(\mathbf{A}\mathbf{x} + \mathbf{b}) + \mathbf{0} = \mathbf{A}\mathbf{x} + \mathbf{b} = t(\mathbf{x}).$$

Thus $t \circ i = i \circ t = t$. Hence i is the identity transformation.

G3 INVERSES If t is an arbitrary affine transformation given by

$$t(\mathbf{x}) = \mathbf{A}\mathbf{x} + \mathbf{b} \quad (\mathbf{x} \in \mathbb{R}^2),$$

then we can define another affine transformation t' by

$$t'(\mathbf{x}) = \mathbf{A}^{-1}\mathbf{x} - \mathbf{A}^{-1}\mathbf{b}.$$

Now for each $\mathbf{x} \in \mathbb{R}^2$, we have

$$\begin{aligned}(t \circ t')(\mathbf{x}) &= t(\mathbf{A}^{-1}\mathbf{x} - \mathbf{A}^{-1}\mathbf{b})\\ &= \mathbf{A}(\mathbf{A}^{-1}\mathbf{x} - \mathbf{A}^{-1}\mathbf{b}) + \mathbf{b}\\ &= (\mathbf{A}\mathbf{A}^{-1}\mathbf{x} - \mathbf{A}\mathbf{A}^{-1}\mathbf{b}) + \mathbf{b}\\ &= (\mathbf{x} - \mathbf{b}) + \mathbf{b}\\ &= \mathbf{x}.\end{aligned}$$

Also,

$$\begin{aligned}(t' \circ t)(\mathbf{x}) &= t'(\mathbf{Ax}+\mathbf{b})\\ &= \mathbf{A}^{-1}(\mathbf{Ax}+\mathbf{b}) - \mathbf{A}^{-1}\mathbf{b}\\ &= (\mathbf{A}^{-1}\mathbf{Ax}+\mathbf{A}^{-1}\mathbf{b}) - \mathbf{A}^{-1}\mathbf{b}\\ &= (\mathbf{x}+\mathbf{A}^{-1}\mathbf{b}) - \mathbf{A}^{-1}\mathbf{b}\\ &= \mathbf{x}.\end{aligned}$$

Thus $t \circ t' = t' \circ t = i$. Hence t' is an inverse for t.

G4 ASSOCIATIVITY Composition of functions is always associative.

It follows that the set of affine transformations $A(2)$ forms a group under composition of functions.

The above proof shows that we can calculate the inverse of an affine transformation by using the following result.

The inverse of the affine transformation $t(\mathbf{x}) = \mathbf{Ax} + \mathbf{b}$ is given by

$$t^{-1}(\mathbf{x}) = \mathbf{A}^{-1}\mathbf{x} - \mathbf{A}^{-1}\mathbf{b}.$$

Problem 3 Find the inverse of the affine transformation

$$t(\mathbf{x}) = \begin{pmatrix}1 & 3\\ 1 & 2\end{pmatrix}\mathbf{x} + \begin{pmatrix}4\\ 2\end{pmatrix}.$$

Having shown that the set of affine transformations forms a group under composition of functions, we now define **affine geometry** to be the study of those properties of figures in the plane $\mathbb{R}^2$ that are preserved by affine transformations. These are the so-called **affine properties** of figures. We begin our investigation of affine geometry by considering the three affine properties listed below.

Basic Properties of Affine Transformations

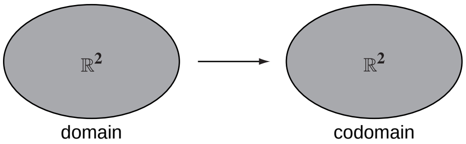
Affine transformations:

1. map straight lines to straight lines;
2. map parallel straight lines to parallel straight lines;
3. preserve ratios of lengths along a given straight line.

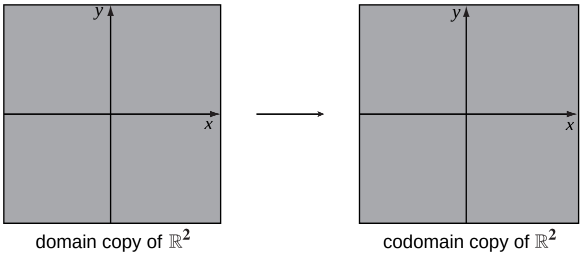
There are two approaches that we shall use to investigate these properties. One approach is to use the definition of an affine transformation to investigate the properties algebraically; we do this in Section 2.3. First, however, we investigate the properties geometrically. We begin to do this in the next subsection by introducing a special type of affine transformation for which there is a simple geometric interpretation.

2.2.2 Parallel Projections

A *parallel projection* is a one–one mapping from $\mathbb{R}^2$ onto itself, defined in the following way. First, we think of its domain and codomain as two separate copies of $\mathbb{R}^2$.



Geometrically, we can represent these copies of $\mathbb{R}^2$ by two separate planes, each equipped with a pair of rectangular axes.

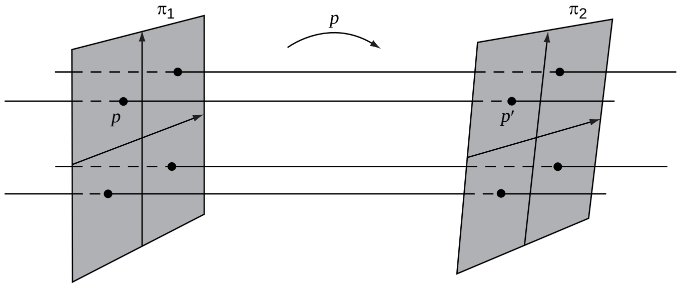


y
x
y
x
domain copy of $\mathbb{R}^2$
codomain copy of $\mathbb{R}^2$

Next we place these planes into three-dimensional space; we denote the domain plane by π_1 and the codomain plane by π_2.

Now imagine parallel rays of light shining through π_1 and π_2. Each point P in the plane π_1 has a (unique) ray passing through it, that also passes through a point P', say, in the plane π_2. This provides us with a one–one correspondence between points in the two planes π_1 and π_2. We call the function p which maps each point P in π_1 to the corresponding point P' in π_2 a **parallel projection from π_1 onto π_2.**

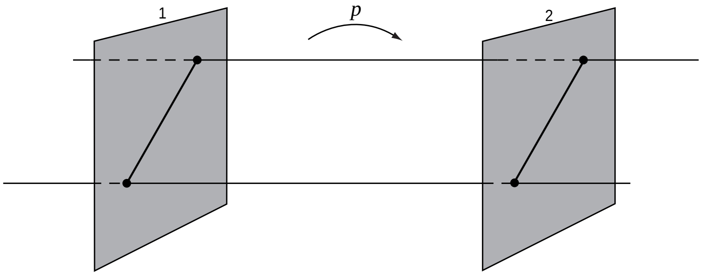
Of course, since π_1 and π_2 represent copies of $\mathbb{R}^2$, a parallel projection is really a function from $\mathbb{R}^2$ onto itself. In Subsection 2.2.3 we show that parallel projections are affine transformations.



If the roles of the planes π_1 and π_2 are reversed, so that π_2 becomes the domain plane and π_1 becomes the codomain plane, then we obtain the inverse function $p\ ^{1}$ which maps points P in $_2$ back to the corresponding points P in $_1$. Clearly, $p\ ^{1}$ is a parallel projection of $_2$ onto $_1$.

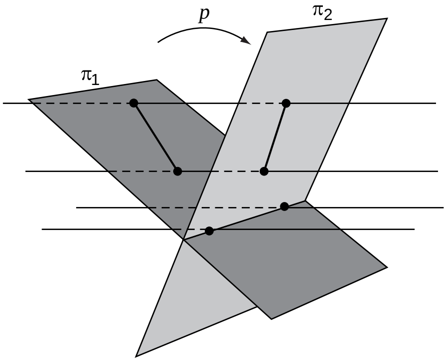
Each choice of location for the domain plane $_1$, and the codomain plane $_2$, and each choice of direction for the rays of light, yields a parallel projection. The only constraint is that the rays of light must not be parallel to either plane.

If the planes $_1$ and $_2$ are parallel to each other, then any parallel projection p from $_1$ onto $_2$ is an isometry, since the distance between any two points is unaltered.



You can envisage the mapping p from $_1$ onto $_2$ as sliding $_1$ parallel to itself along the family of rays .

On the other hand, if the planes are not parallel to each other, then some distances are changed under the projection, and so the parallel projection is not an isometry; notice, however, that distances along the line of intersection of the planes $_1$ and $_2$ do remain unchanged by the parallel projection.



Although distances are not always preserved by a parallel projection, there are some basic properties that are preserved; three of these are listed below. As you will see, these are the same as the basic affine properties that we mentioned at the end of Subsection 2.2.1.

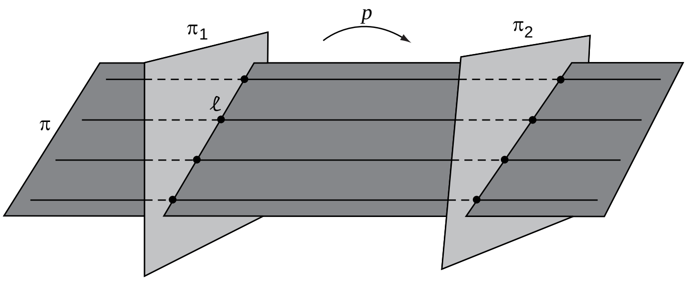
Basic Properties of Parallel Projections
Parallel projections:

1. map straight lines to straight lines;
2. map parallel straight lines to parallel straight lines;
3. preserve ratios of lengths along a given straight line.

Later, we will show that each basic affine property follows directly from the corresponding property for parallel projections. In anticipation of this, we first show that the properties hold for parallel projections.

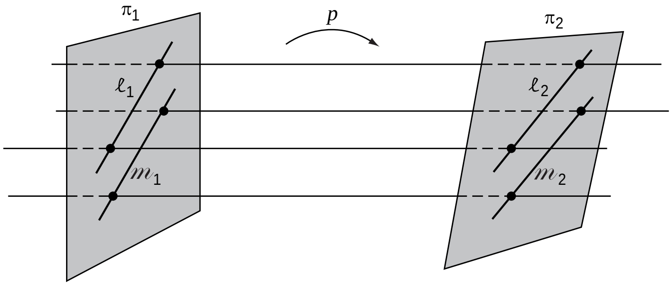
Property 1 A parallel projection maps straight lines to straight lines.

Proof Let ℓ be a line in the plane π_1, and let p be a parallel projection mapping π_1 onto the plane π_2. Now consider all the rays associated with p that pass through ℓ. Since these rays are parallel, they must fill a plane. Call this plane π.



The image of ℓ under p consists of those points where the rays that pass through ℓ meet π_2. But these points are simply the points of intersection of π with π_2. Since any two intersecting planes in $\mathbb{R}^3$ meet in a line, it follows that the image of ℓ under p is a straight line.

Property 2 A parallel projection maps parallel straight lines to parallel straight lines.



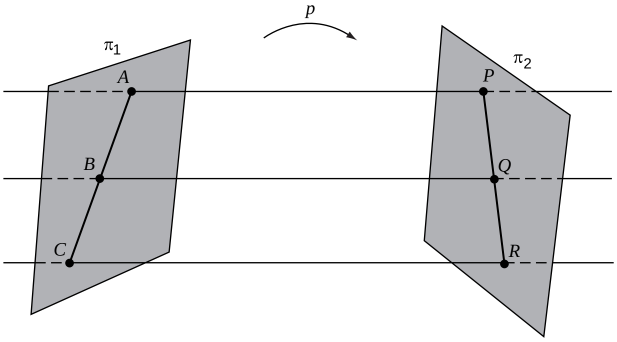
Proof Let ℓ_1 and m_1 be parallel lines in the plane π_1, and let p be a parallel projection mapping π_1 onto the plane π_2. Let ℓ_2 and m_2 be the lines in π_2 that are the images under p of ℓ_1 and m_1.

If ℓ_2 and m_2 are not parallel, they meet at some point, P_2 say. Let P_1 be the point of π_1 which maps to P_2. Then P_1 must lie on both ℓ_1 and m_1. Since ℓ_1 and m_1 are parallel, no such point of intersection can exist, which is a contradiction. It follows that ℓ_2 and m_2 must indeed be parallel.

P_1 is the point $p^{-1}(P_2)$.

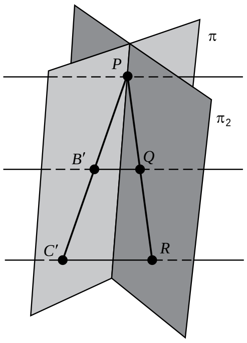
Property 3 A parallel projection preserves ratios of lengths along a given straight line.

We shall give a slightly more general form of this property in Theorem 4 of Subsection 2.3.3.



Proof Let A, B, C be three points on a line in the plane π_1, and let p be a parallel projection mapping π_1 onto the plane π_2. Let P, Q, R be the points in π_2 that are the images under p of A, B, C. We know from Property 1 that P, Q, R lie on a line; we have to show that the ratio $AB : AC$ is equal to the ratio $PQ : PR$.

If the planes π_1 and π_2 are parallel, then the parallel projection p is an isometry, and so the ratios $AB : AC$ and $PQ : PR$ are equal, as required. On the other hand, if π_1 and π_2 are not parallel, then we can construct a plane through the point P which is parallel to π_1, as shown in the margin. This plane intersects the ray through B and Q at some point B', and the ray through C and R at some point C'. So in this case the ratios $AB : AC$ and $PB' : PC'$ are equal.



Now consider $\triangle PC'R$. The lines $B'Q$ and $C'R$ are parallel, since they are rays from the parallel projection. Hence $B'Q$ meets the sides PR and PC' in equal ratios. Thus $PQ : PR = PB' : PC'$. It follows that $PQ : PR = AB : AC$, as required.

Notice, in particular, that if a point is the midpoint of a line segment, then under a parallel projection the image of the point is the midpoint of the image of the line segment.

We make use of this fact in Subsection 2.2.3.

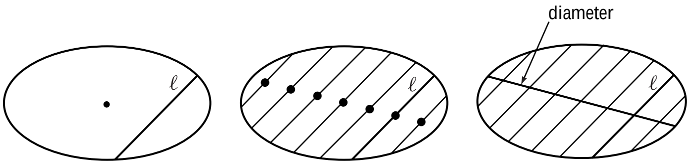
In Subsection 2.2.3 you will see why the basic properties of affine transformations and of parallel projections are the same, and you will meet some further properties of each.

2.2.3 Affine Geometry

In this subsection we explore further the ideas of affine geometry and of parallel projection in order to prove two attractive and unexpected results about ellipses. Also, we examine the relationship between affine transformations and parallel projections.

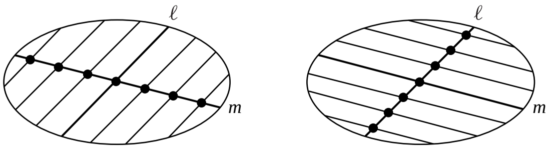
Two Results about Ellipses

First, starting with any chord of an ellipse, draw all the chords parallel to and construct their midpoints. We claim that these midpoints lie on a chord through the centre of the ellipse that is, on a *diameter* of the ellipse.



Theorem 2 Midpoint Theorem
Let be a chord of an ellipse. Then the midpoints of the chords parallel to lie on a diameter of the ellipse.

Next, start with any diameter of an ellipse and construct a second diameter m by following the construction used in Theorem 2, as shown below. Then repeat the construction starting this time with the diameter m; this might reasonably be expected to give us a third diameter of the ellipse but, surprisingly, it gives us the diameter with which we started.



Theorem 3 Conjugate Diameters Theorem
Let be a diameter of an ellipse. Then there is another diameter m of the ellipse such that:

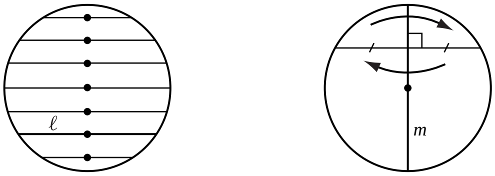
(a) the midpoints of all chords parallel to lie on m;
(b) the midpoints of all chords parallel to m lie on .

The directions of these two diameters are called *conjugate directions*, and the diameters are called *conjugate diameters*.

Proofs for the Special Case of a Circle

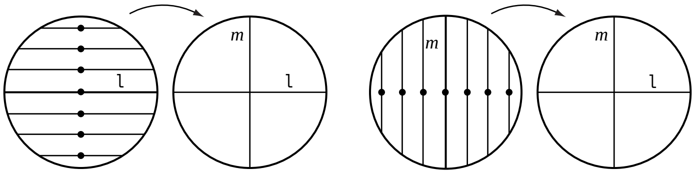
We now investigate these theorems for the special case when the ellipse is a circle. To prove the Midpoint Theorem in this case, start with a chord . If necessary, rotate the circle to ensure that is horizontal. It is then sufficient to prove that every horizontal chord is bisected by the vertical diameter, m.

Recall that a circle is an ellipse with eccentricity zero.



To do this note that the circle is symmetrical about m; so, reflection in m maps that part of every horizontal chord to the left of m exactly onto the part to the right of *m*. Since reflection preserves length, these two parts must be the same length; in other words, *m* bisects each horizontal chord, as required.

What about the Conjugate Diameters Theorem for the special case of the circle?



Start with the horizontal diameter , and carry out the construction of another diameter as in Theorem 2; this yields the vertical diameter m. If we then start with the vertical diameter *m* and repeat the construction, we obtain , the horizontal diameter of the circle. So Theorem 3 certainly holds when the ellipse is a circle.

Generalizing the Proof

We now investigate how the proofs of Theorems 2 and 3 for the circle can be turned into proofs for any kind of ellipse. The crucial fact is as follows.

Theorem 4 Given any ellipse, there is a parallel projection which maps the ellipse onto a circle.

An algebraic proof of a related theorem is given in Theorem 1 of Subsection 2.5.1.

A suitable parallel projection is illustrated below. Here the plane $_1$ (initially parallel to $_2$) has been tilted about the minor axis of the ellipse. Under the projection distances which are parallel to the minor axis remain unchanged, but distances parallel to the major axis are scaled by a factor which depends on the angle of tilt . By choosing just the right amount of tilt we can ensure that the image of the major axis is equal in length to the image of the minor axis, thereby ensuring that the image of the ellipse is a circle.

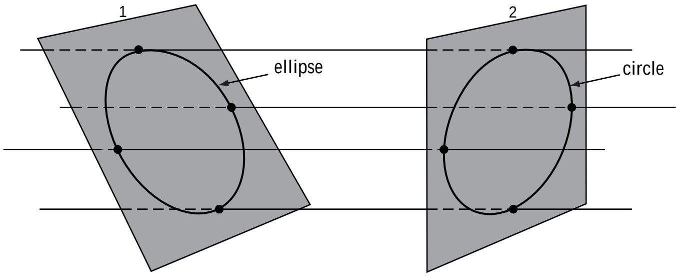
Algebraically, in terms of a suitable coordinate system, the mapping

$$x \qquad \frac{b}{a}x, \quad y \qquad y,$$

maps the ellipse

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1,$$

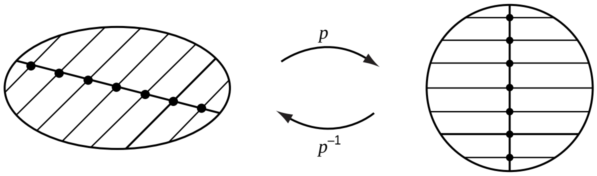
to the circle $x^2 + y^2 = b^2$.



Both Theorems 2 and 3 may now be proved using the following technique. First, map the given ellipse onto a circle, using a suitable parallel projection *p*.

Since we have seen that the theorems hold in the case of the circle, we then map the circle back to the ellipse, using the inverse parallel projection p^{-1}. Now collinearity and parallelism are preserved under a parallel projection, as is the property of being the midpoint of a line segment, so the above two theorems, which hold for a circle, must hold also for the ellipse.

Here we are using Properties 1, 2 and 3 of parallel projections, in a crucial way.



Notice that certain properties of figures, such as length and angle, are not preserved under a parallel projection. This is one difference between Euclidean geometry and affine geometry. The difference arises because the group of affine transformations is larger than the group of Euclidean transformations. In general, the larger the group that is used to define a geometry, the fewer properties the geometry has.

Affine Transformations and Parallel Projections

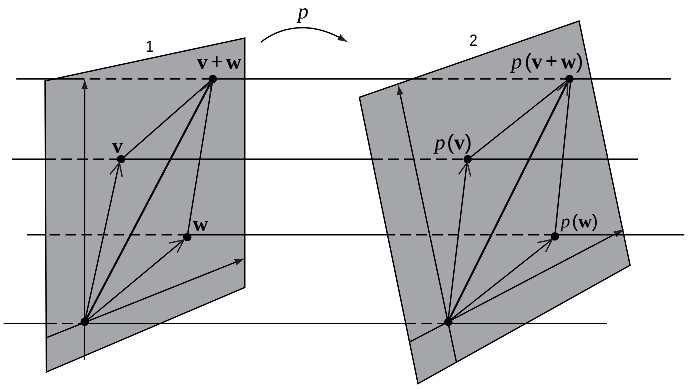
Earlier we mentioned that a parallel projection is a special type of affine transformation. We now show why this is indeed the case.

First, consider a parallel projection p of a plane π_1 onto a plane π_2. For the moment, suppose that the planes are aligned so that the origin in π_1 is mapped to the origin in π_2. Since ratios of lengths are preserved along a straight line, we must have, for any vector $\mathbf{v} \in \mathbb{R}^2$ and any $\lambda \in \mathbb{R}$,

Property 3, Subsection 2.2.2

$$p(\lambda \mathbf{v}) = \lambda p(\mathbf{v}). \qquad (1)$$

Next, let $\mathbf{v}$ and $\mathbf{w}$ be two position vectors in π_1. Their sum, $\mathbf{v} + \mathbf{w}$, is found from the Parallelogram Law for addition of vectors, as shown in the diagram below. The images under p in π_2 are $p(\mathbf{v})$ and $p(\mathbf{w})$, and the sum of these two vectors is $p(\mathbf{v}) + p(\mathbf{w})$.



But a parallel projection maps parallel lines onto parallel lines, so it must map parallelograms onto parallelograms. Hence it must map the parallelogram in $_1$ onto the parallelogram in $_2$, and, in particular, it must map $\mathbf{v} + \mathbf{w}$ to $p(\mathbf{v}) + p(\mathbf{w})$. We may write this as

$$p(\mathbf{v} + \mathbf{w}) = p(\mathbf{v}) + p(\mathbf{w}). \qquad (2)$$

It follows from equations (1) and (2) that p must be a *linear* transformation of $\mathbb{R}^2$ onto itself.

Remember that $_1$ and $_2$ represent copies of $\mathbb{R}^2$.

Hence there exists some matrix $\mathbf{A}$ such that for each $\mathbf{v} \quad \mathbb{R}^2$,

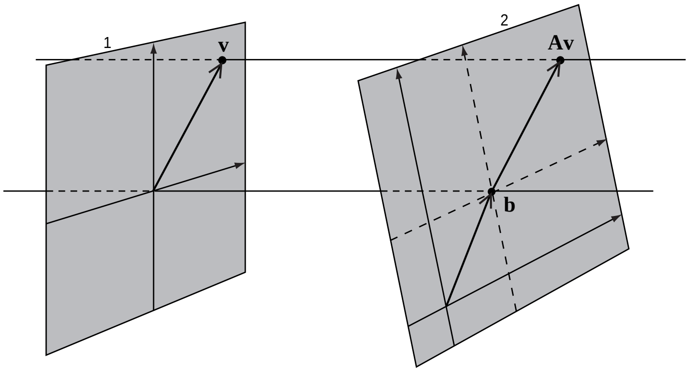
$$p(\mathbf{v}) = \mathbf{A}\mathbf{v}. \qquad (3)$$

Since the linear transformation p is invertible, it follows that $\mathbf{A}$ is invertible.

Now suppose that the parallel projection maps the origin in $_1$ to some point B with position vector $\mathbf{b}$ in $_2$, as shown below. If we temporarily construct a new set of axes in $_2$ that are parallel to the original axes, but which intersect at the point B, then with respect to these new axes $p(\mathbf{v}) = \mathbf{A}\mathbf{v}$ for some invertible matrix $\mathbf{A}$, as before. To express $p(\mathbf{v})$ with respect to the original axes, we simply add on the vector $\mathbf{b}$ to obtain

$$p(\mathbf{v}) = \mathbf{A}\mathbf{v} + \mathbf{b} \qquad (4)$$

for some invertible 2 × 2 matrix $\mathbf{A}$.



It follows from equation (4) that p must be an affine transformation.

Theorem 5 Each parallel projection is an affine transformation.

The converse is false, for it is *not* true that every affine transformation can be represented as a parallel projection.

For example, consider the so-called doubling map of $\mathbb{R}^2$ to itself given by

$$t(\mathbf{v}) = 2\mathbf{v} \quad (\mathbf{v} \quad \mathbb{R}^2). \qquad (5)$$

This is an affine transformation, since it can be written in the form $t(\mathbf{x}) = \mathbf{Ax}+\mathbf{b}$ with $\mathbf{A} = 2\mathbf{I}$ and $\mathbf{b} = \mathbf{0}$. However, a parallel projection is *either* between two parallel planes, in which case all lengths are unchanged, *or* between two intersecting planes, in which case distances along the line of intersection are unchanged. The doubling map has neither of these properties and so is not a parallel projection.

Observation An affine transformation is not necessarily a parallel projection.

Although the doubling map is not a parallel projection, it *is* possible to double lengths in $\mathbb{R}^2$ by following one parallel projection by another: the first doubles all horizontal lengths, and the second doubles all vertical lengths. Thus the doubling map (5) can be represented as the *composition* of two parallel projections.

We end this subsection by showing that *every* affine transformation can be expressed as a composition of two parallel projections.

Recall that any affine transformation $t : \mathbb{R}^2 \to \mathbb{R}^2$ has the form

$$t(\mathbf{x}) = \mathbf{Ax} + \mathbf{b} \quad (\mathbf{x} \in \mathbb{R}^2), \tag{6}$$

where $\mathbf{A}$ is an invertible 2×2 matrix. Now, t is not a linear transformation unless $\mathbf{b} = \mathbf{0}$, but we can use methods similar to those for linear transformations to determine $\mathbf{A}$ and $\mathbf{b}$.

First, it follows from equation (6) that $t(\mathbf{0}) = \mathbf{b}$; so $\mathbf{b}$ is the image of the origin under t. If we let e and f be the coordinates of $t(\mathbf{0})$, then we can write

$$\mathbf{A} = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \quad \text{and} \quad \mathbf{b} = \begin{pmatrix} e \\ f \end{pmatrix},$$

where a, b, c, d are real numbers that have yet to be found. It follows from equation (6) that the images under t of the points (1, 0) and (0, 1) are given by

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix}\begin{pmatrix} 1 \\ 0 \end{pmatrix} + \begin{pmatrix} e \\ f \end{pmatrix} = \begin{pmatrix} a \\ c \end{pmatrix} + \begin{pmatrix} e \\ f \end{pmatrix}$$

and

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix}\begin{pmatrix} 0 \\ 1 \end{pmatrix} + \begin{pmatrix} e \\ f \end{pmatrix} = \begin{pmatrix} b \\ d \end{pmatrix} + \begin{pmatrix} e \\ f \end{pmatrix}.$$

So if, in addition to $t(\mathbf{0}) = (e, f)$, we know the points onto which (1, 0) and (0, 1) are mapped by t, then we can determine the values of a, b, c and d. Indeed, we have

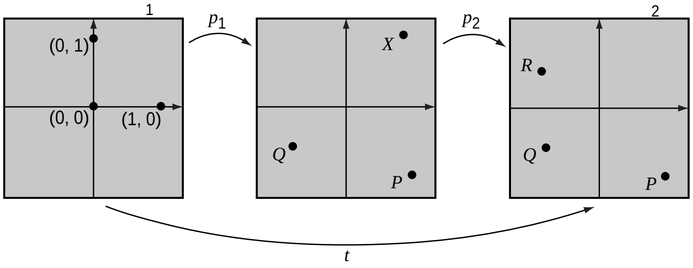
$$(a, c) = t(1, 0) - (e, f) \quad \text{and} \quad (b, d) = t(0, 1) - (e, f).$$

Notice that for an affine transformation t, the images $t(1, 0)$, $t(0, 1)$ and $t(0, 0) = (e, f)$ cannot be collinear, for if they were, then (a, c) and (b, d) would be linearly dependent, and $\mathbf{A}$ would not be invertible.

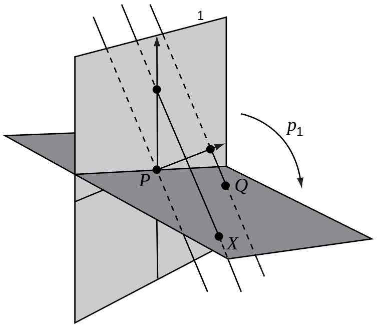
It follows that an affine transformation is *uniquely* determined by its effect on the three non-collinear points (0, 0), (1, 0) and (0, 1). We shall return to this method of determining affine transformations in Section 2.3.

So suppose that a given affine transformation t maps the points (0, 0), (1, 0) and (0, 1) to three non-collinear points P, Q and R, respectively. In order to express t as the composition of two parallel projections p_1 and p_2, we need to define p_1 and p_2 in such a way that $p_2 \circ p_1$ has the same effect as t on (0, 0), (1, 0) and (0, 1). To do this, we first define p_1 so that it maps (0, 0) to P, (1, 0) to Q, and (0, 1) to some point X, say, and then define p_2 so that it maps X to R while leaving P and Q fixed.

Uniqueness then guarantees that $t = p_2 \circ p_1$.



To construct p_1 we embed its domain plane π_1, and its codomain plane π, into $\mathbb{R}^3$ so that the point (0, 0) in π_1 coincides with the point P in π, as shown below. It does not matter how this is done, provided that (1, 0) does not lie in π. We then define p_1 by the family of rays that are parallel to the ray through the point (1, 0) in π_1 and the point Q in π. When defined in this way, p_1 maps (0, 0) to P, (1, 0) to Q, and (0, 1) to some point X, as required.

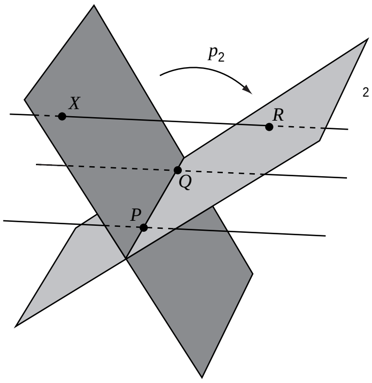


For clarity, we have omitted the axes from the plane π.

To construct p_2 we embed its domain plane π, and its codomain plane π_2, into $\mathbb{R}^3$ so that the points P and Q in π coincide with the points P and Q in π_2, as shown below. Again it does not matter how this is done, provided that X does not lie in π_2. We then define p_2 by the family of rays that are parallel to the ray through the point X in π and the point R in π_2. Then p_2 leaves P and Q fixed and maps X to R.

See the figure below.

Overall, the composite $p_2 \circ p_1$ of the two parallel projections maps (0, 0), (1, 0) and (0, 1) to P, Q and R, respectively. Now p_1 and p_2 are affine transformations, so $p_2 \circ p_1$ is also an affine transformation. Furthermore, $p_2 \circ p_1$ maps



(0, 0), (1, 0) and (0, 1) to the same points as does t. Since such affine transformations are unique, it follows that $t = p_2 \circ p_1$. We have therefore demonstrated the following result.

Theorem 6 An affine transformation can be expressed as the composite of two parallel projections.

An important consequence of this theorem is that all properties of figures that are unchanged by parallel projections must also be unchanged by affine transformations. In particular, the three properties of parallel projections that we met in Subsection 2.2.2 must, in fact, be affine properties.

2.3 Properties of Affine Transformations

In the previous section you saw how parallel projections can be used to explore affine geometry from a visual point of view. In this section we explore some of the same ideas from an algebraic point of view.

2.3.1 Images of Sets Under Affine Transformations

We begin by describing how to find the image of a line under an affine transformation. To do this, recall that an affine transformation is a mapping $t : \mathbb{R}^2 \to \mathbb{R}^2$ given by a formula of the form

$$t(\mathbf{x}) = \mathbf{Ax} + \mathbf{b}, \tag{1}$$

where $\mathbf{A}$ is an invertible 2 × 2 matrix. The set of such transformations forms a group, in which the transformation inverse to t is given by

$$t^{-1}(\mathbf{x}) = \mathbf{A}^{-1}\mathbf{x} - \mathbf{A}^{-1}\mathbf{b}. \tag{2}$$

Subsection 2.2.1

When equations (1) and (2) are used to find images under t, it is easy to confuse points in the domain plane with points in the codomain plane, as both planes are copies of $\mathbb{R}^2$. To avoid such confusion, we often reserve the symbol $\mathbf{x}$ and the coordinates (x, y) for points in the domain of t, and use the symbol $\mathbf{x}'$ and the coordinates (x', y') to denote the image of $\mathbf{x}$ under t.

With this notation, we may rewrite equations (1) and (2) in the form

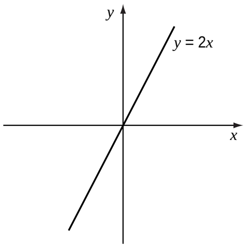
$$\mathbf{x}' = \mathbf{A}\mathbf{x} + \mathbf{b}, \tag{3}$$

$$\mathbf{x} = \mathbf{A}^{-1}\mathbf{x}' - \mathbf{A}^{-1}\mathbf{b}. \tag{4}$$

The next example illustrates how these equations can be used to find the image of a line under an affine transformation.

Example 1 Determine the image of the line $y = 2x$ under the affine transformation

$$t(\mathbf{x}) = \begin{pmatrix} 4 & 1 \\ 2 & 1 \end{pmatrix}\mathbf{x} + \begin{pmatrix} 2 \\ -1 \end{pmatrix} \quad (\mathbf{x} \in \mathbb{R}^2). \tag{5}$$



Solution Let (x, y) be an arbitrary point on the line $y = 2x$, and let (x', y') be the image of (x, y) under t. Then

$$\begin{pmatrix} x' \\ y' \end{pmatrix} = \begin{pmatrix} 4 & 1 \\ 2 & 1 \end{pmatrix}\begin{pmatrix} x \\ y \end{pmatrix} + \begin{pmatrix} 2 \\ -1 \end{pmatrix}.$$

Next we use equation (4) to express (x, y) in terms of (x', y'). We have

$$\begin{pmatrix} 4 & 1 \\ 2 & 1 \end{pmatrix}^{-1} = \begin{pmatrix} \frac{1}{2} & -\frac{1}{2} \\ -1 & 2 \end{pmatrix} \quad \text{and} \quad \begin{pmatrix} \frac{1}{2} & -\frac{1}{2} \\ -1 & 2 \end{pmatrix}\begin{pmatrix} 2 \\ -1 \end{pmatrix} = \begin{pmatrix} \frac{3}{2} \\ -4 \end{pmatrix},$$

Recall that the inverse of the invertible matrix $\mathbf{A} = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$ is

$$\mathbf{A}^{-1} = \frac{1}{ad - bc} \times \begin{pmatrix} d & -b \\ -c & a \end{pmatrix}.$$

so

$$\begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} \frac{1}{2} & -\frac{1}{2} \\ -1 & 2 \end{pmatrix}\begin{pmatrix} x' \\ y' \end{pmatrix} + \begin{pmatrix} -\frac{3}{2} \\ 4 \end{pmatrix}.$$

It follows that under the inverse mapping t^{-1} we have

$$x = \tfrac{1}{2}x' - \tfrac{1}{2}y' - \tfrac{3}{2} \quad \text{and} \quad y = -x' + 2y' + 4.$$

Since x and y are related by the equation $y = 2x$, it follows that x' and y' are related by the equation

$$-x' + 2y' + 4 = 2\left(\tfrac{1}{2}x' - \tfrac{1}{2}y' - \tfrac{3}{2}\right),$$

which simplifies to

$$2x' - 3y' = 7.$$

Dropping the dashes, we see that the image of the line $y = 2x$ under t is the line

$$2x - 3y = 7.$$ □

Problem 1 Determine the image of the line $3x \quad y + 1 = 0$ under the affine transformation

$$t(\mathbf{x}) = \begin{pmatrix} \frac{1}{2} & \frac{1}{2} \\ 1 & 2 \end{pmatrix} \mathbf{x} + \begin{pmatrix} \frac{3}{2} \\ 4 \end{pmatrix} \qquad \mathbf{x} \quad \mathrm{R}^2 .$$

Problem 2 Determine the image of the circle $x^2 + y^2 = 1$ under the affine transformation

$$t(\mathbf{x}) = \begin{pmatrix} \frac{1}{2} & \frac{1}{2} \\ 1 & 2 \end{pmatrix} \mathbf{x} + \begin{pmatrix} \frac{3}{2} \\ 4 \end{pmatrix} \qquad \mathbf{x} \quad \mathrm{R}^2 .$$

The same technique can be used to find the images of other types of figures, such as other conics. You will meet some examples of this in Section 2.5.

2.3.2 The Fundamental Theorem of Affine Geometry

The algebraic approach can also be used to investigate whether there is an affine transformation which maps one given figure onto another. Recall that if there is such a transformation, then the two figures are said to be **affine-congruent**. This concept of congruence is important because, as we explained in Section 2.1, figures that are affine-congruent to each other share the same affine properties.

In this subsection we prove the remarkable result that *all* triangles are affine-congruent and therefore share the same affine properties. In fact, since a triangle is completely determined by its three vertices, the congruence of triangles follows from the so-called *Fundamental Theorem of Affine Geometry* which states that any three non-collinear points can be mapped to any other three non-collinear points by an affine transformation.

This is very different to Euclidean geometry, where two triangles are congruent only if they have the same shape and size.

First, recall that in Subsection 2.2.3 we described how the points (0, 0), (1, 0) and (0, 1) in R^2 can be mapped to any three non-collinear points P, Q and R by an affine transformation. This transformation is unique in the sense that it is completely determined by the choice of P, Q and R. The following example should remind you of how such transformations are constructed.

There the mapping was constructed in a geometric manner. In this subsection we construct the mapping algebraically.

Example 2 Determine the affine transformation which maps the points (0, 0), (1, 0) and (0, 1) to the points (3, 2), (5, 8) and (7, 3), respectively.

Solution Let t be the affine transformation given by

$$t : \begin{pmatrix} x \\ y \end{pmatrix} \qquad \begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} + \begin{pmatrix} e \\ f \end{pmatrix} . \tag{6}$$

Since $t(0, 0) = (3, 2)$, it follows from (6) that $e = 3$ and $f = 2$.

Next, $t(1, 0) = (5, 8)$, so it follows from (6) that

$$\begin{pmatrix} 5 \\ 8 \end{pmatrix} = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} 1 \\ 0 \end{pmatrix} + \begin{pmatrix} 3 \\ 2 \end{pmatrix} = \begin{pmatrix} a \\ c \end{pmatrix} + \begin{pmatrix} 3 \\ 2 \end{pmatrix} .$$

The first column of the matrix for t is therefore

$$\begin{pmatrix} a \\ c \end{pmatrix} = \begin{pmatrix} 5 \\ 8 \end{pmatrix} - \begin{pmatrix} 3 \\ 2 \end{pmatrix} = \begin{pmatrix} 2 \\ 6 \end{pmatrix}.$$

Finally, $t(0,1) = (7,3)$, so that

$$\begin{pmatrix} 7 \\ 3 \end{pmatrix} = \begin{pmatrix} a & b \\ c & d \end{pmatrix}\begin{pmatrix} 0 \\ 1 \end{pmatrix} + \begin{pmatrix} 3 \\ 2 \end{pmatrix} = \begin{pmatrix} b \\ d \end{pmatrix} + \begin{pmatrix} 3 \\ 2 \end{pmatrix}.$$

The second column of the matrix for t is therefore

$$\begin{pmatrix} b \\ d \end{pmatrix} = \begin{pmatrix} 7 \\ 3 \end{pmatrix} - \begin{pmatrix} 3 \\ 2 \end{pmatrix} = \begin{pmatrix} 4 \\ 1 \end{pmatrix}.$$

Hence the desired affine transformation is given by

$$t : \begin{pmatrix} x \\ y \end{pmatrix} \mapsto \begin{pmatrix} 2 & 4 \\ 6 & 1 \end{pmatrix}\begin{pmatrix} x \\ y \end{pmatrix} + \begin{pmatrix} 3 \\ 2 \end{pmatrix}. \qquad \square$$

In general, if we want to find an affine transformation t of the form

$$t : \begin{pmatrix} x \\ y \end{pmatrix} \mapsto \begin{pmatrix} a & b \\ c & d \end{pmatrix}\begin{pmatrix} x \\ y \end{pmatrix} + \begin{pmatrix} e \\ f \end{pmatrix} \qquad (7)$$

which maps (0, 0) to **p**, (1, 0) to **q** and (0, 1) to **r**, then we must choose a, b, c, d, e and f so that

$$\begin{aligned} \mathbf{p} &= t(0,0) = (e, f), && \text{so } (e, f) = \mathbf{p}; \\ \mathbf{q} &= t(1,0) = (a,c) + (e, f), && \text{so } (a,c) = \mathbf{q} - \mathbf{p}; \\ \mathbf{r} &= t(0,1) = (b,d) + (e, f), && \text{so } (b,d) = \mathbf{r} - \mathbf{p}. \end{aligned}$$

Notice that any three points **p**, **q** and **r** uniquely determine a transformation t of the form (7), but t is *affine* only if the matrix

$$\mathbf{A} = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$$

is invertible. Since the columns of **A** correspond to the vectors **q** − **p** and **r** − **p**, it follows that **A** is invertible only if the vectors **q** − **p** and **r** − **p** are linearly independent. That is, provided that **p**, **q** and **r** are *not* collinear.

So if **p**, **q** and **r** are *not* collinear, then we can use the following strategy to find an affine transformation which maps (0, 0) to **p**, (1, 0) to **q** and (0, 1) to **r**.

Strategy To determine the unique affine transformation $t(\mathbf{x}) = \mathbf{A}\mathbf{x} + \mathbf{b}$ which maps (0, 0), (1, 0) and (0, 1) to the three non-collinear points **p, q** and **r**, respectively:

1. take $\mathbf{b} = \mathbf{p}$;
2. take **A** to be the matrix with columns given by **q** − **p** and **r** − **p**.

Problem 3 Use the strategy to determine the affine transformation which maps the points (0, 0), (1, 0) and (0, 1) to the points (2, 3), (1, 6) and (3, −1), respectively.

Problem 4 Use the strategy to determine the affine transformation which maps the points (0, 0), (1, 0) and (0, 1) to the points (1, −2), (2, 1) and (−3, 5), respectively.

We shall use the results of these two problems shortly, in Example 3.

Notice that the inverse of the transformation in Problem 3 is an affine transformation which maps the points (2, 3), (1, 6) and (3, −1) to the points (0, 0), (1, 0) and (0, 1), respectively. So if, after applying this inverse, we apply the affine transformation in Problem 4, then the overall effect is that of a composite affine transformation which sends the points (2, 3), (1, 6) and (3, −1) to the points (1, −2), (2, 1) and (−3, 5), respectively.

In a similar way, we can find an affine transformation which sends any three non-collinear points to any other three non-collinear points.

$(2,3)$	$(0,0)$	$(1,-2)$
$(1,6)$	$(1,0)$	$(2,1)$
$(3,-1)$	$(0,1)$	$(-3,5)$

Theorem 1 Fundamental Theorem of Affine Geometry

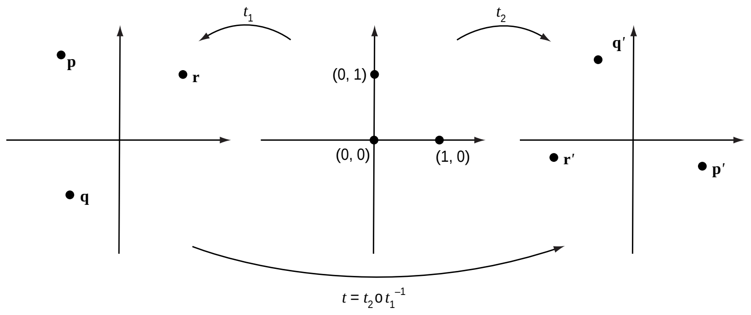
Let **p**, **q**, **r** and **p′**, **q′**, **r′** be two sets of three non-collinear points in $\mathbb{R}^2$. Then:

(a) there is an affine transformation t which maps **p**, **q** and **r** to **p′**, **q′** and **r′**, respectively;

(b) the affine transformation t is unique.

Proof

(a) Let t_1 be the affine transformation which maps (0, 0), (1, 0) and (0, 1) to the points **p**, **q** and **r**, respectively, and let t_2 be the affine transformation which maps (0, 0), (1, 0) and (0, 1) to the points **p′**, **q′** and **r′**, respectively. Then the composite $t = t_2 \circ t_1^{-1}$ is an affine transformation, and it maps **p**, **q** and **r** to **p′**, **q′** and **r′**, respectively.



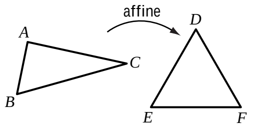
$$\mathbf{p} \xrightarrow{t_1^{-1}} (0,0) \xrightarrow{t_2} \mathbf{p}'$$
$$\mathbf{q} \quad (1,0) \quad \mathbf{q}'$$
$$\mathbf{r} \quad (0,1) \quad \mathbf{r}'$$

(b) Suppose that t and s are both affine transformations which map $\mathbf{p}$, $\mathbf{q}$ and $\mathbf{r}$ to $\mathbf{p}'$, $\mathbf{q}'$ and $\mathbf{r}'$, respectively, and let t_1 be the affine transformation defined in part (a). Then the composites $t \circ t_1$ and $s \circ t_1$ are both affine transformations which map (0, 0), (1, 0) and (0, 1) to $\mathbf{p}'$, $\mathbf{q}'$ and $\mathbf{r}'$, respectively. Since an affine transformation is uniquely determined by its effect on the points (0, 0), (1, 0) and (0, 1), it follows that $t \circ t_1 = s \circ t_1$.

If we then compose both $t \circ t_1$ and $s \circ t_1$ on the right with t_1^{-1}, it follows that $t = s$. Thus the mapping t constructed in part (a) is unique.

$$\begin{array}{lcccc} (0,0) & \xrightarrow{t_1} & \mathbf{p} & \xrightarrow{t \text{ or } s} & \mathbf{p}' \\ (1,0) & \to & \mathbf{q} & \to & \mathbf{q}' \\ (0,1) & \to & \mathbf{r} & \to & \mathbf{r}' \end{array}$$

Now suppose that we are given two arbitrary triangles $\triangle ABC$ and $\triangle DEF$. By the Fundamental Theorem there is an affine transformation which maps the vertices A, B, C to the vertices D, E, F, respectively. Since this transformation maps straight lines to straight lines, it must map the sides of $\triangle ABC$ to the sides of $\triangle DEF$, so we have the following important corollary. This will be used extensively in Section 2.4.



Corollary All triangles are affine-congruent.

In order to find the affine transformation which maps one triangle, vertex to vertex, onto another triangle, we follow the strategy used in part (a) of the proof of the Fundamental Theorem.

Strategy To determine the affine transformation t which maps three non-collinear points $\mathbf{p}$, $\mathbf{q}$ and $\mathbf{r}$ to another three non-collinear points $\mathbf{p}'$, $\mathbf{q}'$ and $\mathbf{r}'$, respectively:

1. determine the affine transformation t_1 which maps (0, 0), (1, 0) and (0, 1) to the points $\mathbf{p}$, $\mathbf{q}$ and $\mathbf{r}$, respectively;
2. determine the affine transformation t_2 which maps (0, 0), (1, 0) and (0, 1) to the points $\mathbf{p}'$, $\mathbf{q}'$ and $\mathbf{r}'$, respectively;
3. calculate the composite $t = t_2 \circ t_1^{-1}$.

Recall that the previous strategy explained how t_1 and t_2 can be determined.

Example 3 Determine the affine transformation which maps the points (2, 3), (1, 6) and (3, −1) to the points (1, −2), (2, 1) and (−3, 5), respectively.

Solution You have already seen in Problem 3 that the affine transformation t_1 which maps the points (0, 0), (1, 0) and (0, 1) to the points (2, 3), (1, 6) and (3, −1), respectively, is given by

$$t_1(\mathbf{x}) = \begin{pmatrix} -1 & 1 \\ 3 & -4 \end{pmatrix} \mathbf{x} + \begin{pmatrix} 2 \\ 3 \end{pmatrix}.$$

Also, in Problem 4 you saw that the affine transformation t_2 which maps the points (0, 0), (1, 0) and (0, 1) to the points (1, 2), (2, 1) and (3, 5), respectively, is given by

$$t_2(\mathbf{x}) = \begin{matrix} 1 & 4 \\ 3 & 7 \end{matrix} \mathbf{x} + \begin{matrix} 1 \\ 2 \end{matrix} .$$

Following the strategy, we need to find the inverse of t_1. We have

$$\begin{matrix} 1 & 1 \\ 3 & 4 \end{matrix}^{1} = \begin{matrix} 4 & 1 \\ 3 & 1 \end{matrix}$$

and

$$\begin{matrix} 4 & 1 \\ 3 & 1 \end{matrix} \begin{matrix} 2 \\ 3 \end{matrix} = \begin{matrix} 11 \\ 9 \end{matrix} ,$$

so that the inverse of t_1 is given by

$$t_1^{\;1}(\mathbf{x}) = \begin{matrix} 4 & 1 \\ 3 & 1 \end{matrix} \mathbf{x} + \begin{matrix} 11 \\ 9 \end{matrix} .$$

Thus the affine transformation which maps the points (2, 3), (1, 6) and (3, 1) to the points (1, 2), (2, 1) and (3, 5), respectively, is given by

$$\begin{aligned} t(\mathbf{x}) &= t_2 \quad t_1^{\;1}(\mathbf{x}) \\ &= t_2 \quad \begin{matrix} 4 & 1 \\ 3 & 1 \end{matrix} \mathbf{x} + \begin{matrix} 11 \\ 9 \end{matrix} \\ &= \begin{matrix} 1 & 4 \\ 3 & 7 \end{matrix} \quad \begin{matrix} 4 & 1 \\ 3 & 1 \end{matrix} \mathbf{x} + \begin{matrix} 11 \\ 9 \end{matrix} \quad + \begin{matrix} 1 \\ 2 \end{matrix} \\ &= \quad \begin{matrix} 8 & 3 \\ 33 & 10 \end{matrix} \mathbf{x} + \begin{matrix} 25 \\ 96 \end{matrix} \quad + \begin{matrix} 1 \\ 2 \end{matrix} \\ &= \quad \begin{matrix} 8 & 3 \\ 33 & 10 \end{matrix} \mathbf{x} + \begin{matrix} 24 \\ 94 \end{matrix} . \end{aligned}$$

□

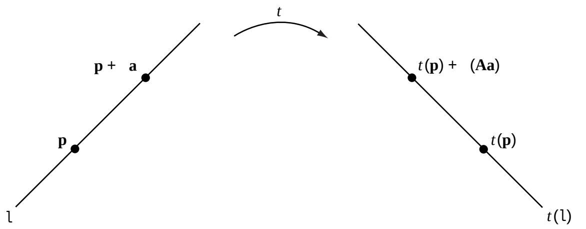
Problem 5 Determine the affine transformation which maps the points (1, 1), (2, 2) and (3, 4) to the points (8, 13), (3, 4) and (0, 1), respectively.

2.3.3 Proofs of the Basic Properties of Affine Transformations

In Subsection 2.2.2 we used parallel projections to demonstrate that affine transformations have the following basic properties: they map straight lines to straight lines, they map parallel lines to parallel lines, and they preserve ratios of lengths along a given straight line. We now give algebraic proofs of these assertions.

Theorem 2 An affine transformation maps straight lines to straight lines.

Proof



t
$\mathbf{p} + \lambda\mathbf{a}$
$\mathbf{p}$
ℓ
$t(\mathbf{p}) + \lambda(\mathbf{Aa})$
$t(\mathbf{p})$
$t(\ell)$

Let ℓ be a line through a point with position vector $\mathbf{p}$, and let the direction of ℓ be that of some vector $\mathbf{a}$. Then

$$\ell = \{\mathbf{p} + \lambda\mathbf{a} : \lambda \in \mathbb{R}\}.$$

Now let $t : \mathbb{R}^2 \to \mathbb{R}^2$ be an affine transformation given by

$$t(\mathbf{x}) = \mathbf{Ax} + \mathbf{b}.$$

We can find the image under t of an arbitrary point $\mathbf{p} + \lambda\mathbf{a}$ on ℓ as follows:

$$\begin{aligned} t(\mathbf{p} + \lambda\mathbf{a}) &= \mathbf{A}(\mathbf{p} + \lambda\mathbf{a}) + \mathbf{b} \\ &= (\mathbf{Ap} + \mathbf{b}) + \lambda\mathbf{Aa} \\ &= t(\mathbf{p}) + \lambda\mathbf{Aa}. \end{aligned}$$

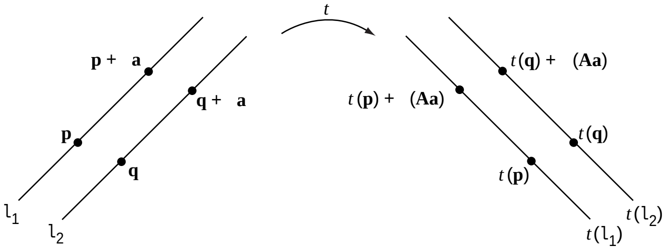
So the image of ℓ is the set

$$t(\ell) = \{t(\mathbf{p}) + \lambda\mathbf{Aa} : \lambda \in \mathbb{R}\},$$

which is a line through $t(\mathbf{p})$ in the direction of the vector $\mathbf{Aa}$.

Theorem 3 An affine transformation maps parallel straight lines to parallel straight lines.

Proof



t
$\mathbf{p} + \lambda\mathbf{a}$
$\mathbf{q} + \lambda\mathbf{a}$
$\mathbf{p}$
$\mathbf{q}$
ℓ_1
ℓ_2
$t(\mathbf{q}) + \lambda(\mathbf{Aa})$
$t(\mathbf{p}) + \lambda(\mathbf{Aa})$
$t(\mathbf{q})$
$t(\mathbf{p})$
$t(\ell_2)$
$t(\ell_1)$

Let ℓ_1 and ℓ_2 be parallel lines through the points with position vectors $\mathbf{p}$ and $\mathbf{q}$, respectively, and let the direction of the lines be that of the vector $\mathbf{a}$. Then

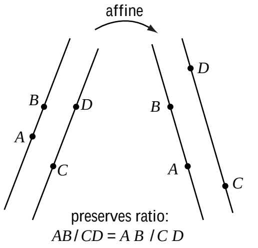
$$\ell_1 = \{\mathbf{p} + \lambda\mathbf{a} : \lambda \in \mathbb{R}\} \quad \text{and} \quad \ell_2 = \{\mathbf{q} + \lambda\mathbf{a} : \lambda \in \mathbb{R}\}.$$

As in the proof of Theorem 2, the images of ℓ_1 and ℓ_2 under the affine transformation $t(\mathbf{x}) = \mathbf{Ax} + \mathbf{b}$ are the sets

$$t(\ell_1) = \{t(\mathbf{p}) + \lambda\mathbf{Aa} : \lambda \in \mathbb{R}\} \quad \text{and} \quad t(\ell_2) = \{t(\mathbf{q}) + \lambda\mathbf{Aa} : \lambda \in \mathbb{R}\}.$$

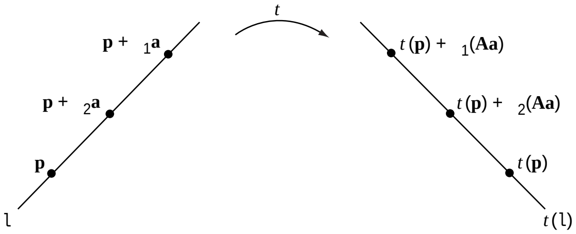
These sets are straight lines which pass through the image points $t(\mathbf{p})$ and $t(\mathbf{q})$, both in the same direction as that of the vector $\mathbf{Aa}$. Hence the two image lines under t are parallel, as claimed.

Rather than prove that affine transformations preserve ratios of lengths along a given straight line, as in Property 3 of Subsection 2.2.2, we prove the following more general result illustrated in the margin. The original result follows because any line is parallel to itself.



Theorem 4 An affine transformation preserves ratios of lengths along parallel straight lines.

Proof We begin by examining what happens to the length of a line segment under an affine transformation.



Let ℓ be a line through a point with position vector $\mathbf{p}$, and let the direction of ℓ be that of some *unit* vector $\mathbf{a}$. Then

$$\ell = \{\mathbf{p} + \lambda\mathbf{a} : \lambda \in \mathbb{R}\}.$$

As in the proof of Theorem 2, the image of ℓ under the affine transformation $t(\mathbf{x}) = \mathbf{Ax} + \mathbf{b}$ is the line

$$t(\ell) = \{t(\mathbf{p}) + \lambda\mathbf{Aa} : \lambda \in \mathbb{R}\}.$$

Now consider a segment of ℓ with endpoints $\mathbf{p} + \lambda_1\mathbf{a}$ and $\mathbf{p} + \lambda_2\mathbf{a}$. Since $\mathbf{a}$ is a unit vector, the length of the segment is

$$\|(\mathbf{p} + \lambda_2\mathbf{a}) - (\mathbf{p} + \lambda_1\mathbf{a})\| = |\lambda_2 - \lambda_1| \bullet \|\mathbf{a}\| = |\lambda_2 - \lambda_1|.$$

Recall that $\|\mathbf{a}\|$ means the length of $\mathbf{a}$.

The image of the segment has endpoints $t(\mathbf{p}) + \lambda_1\mathbf{Aa}$ and $t(\mathbf{p}) + \lambda_2\mathbf{Aa}$, so the image of the segment has length

$$\|(t(\mathbf{p}) + \lambda_2\mathbf{Aa}) - (t(\mathbf{p}) + \lambda_1\mathbf{Aa})\| = |\lambda_2 - \lambda_1| \bullet \|\mathbf{Aa}\|.$$

So, in the process of mapping segments along ℓ to segments along $t(\ell)$, lengths are stretched by the factor $\|\mathbf{Aa}\|$. Since this factor is the same for all segments which lie along lines parallel to $\mathbf{a}$, it follows that the *ratios* of lengths along parallel lines are unchanged by t.

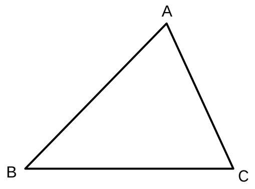
2.4 Using the Fundamental Theorem of Affine Geometry

In this section we explain how the Fundamental Theorem of Affine Geometry can be used to deduce the fact that the medians of any triangle are concurrent from the special case that the medians of an equilateral triangle are concurrent. We then use similar methods to prove the classical theorems of Ceva and Menelaus.

These results are named after Giovanni Ceva (Italian mathematician, 1647/48–1734) and Menelaus of Alexandria (Greek geometer, 1st Century AD).

2.4.1 The Median Theorem

Let $\triangle ABC$ be an arbitrary triangle in the plane. If you join the midpoint of each side of the triangle to the opposite vertex (these lines are called the *medians* of the triangle), these three lines appear to pass through a single point. In fact, no matter what triangle you choose, you find that its medians meet in a single point.

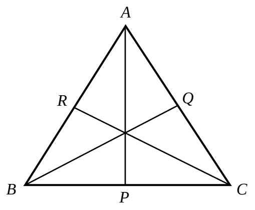


Theorem 1 Median Theorem
The medians of any triangle are concurrent.

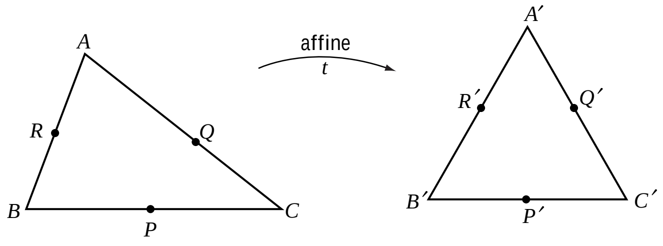
We can get some evidence that this theorem holds in general by looking first at a special case where a proof of the theorem is straight-forward — namely, when the triangle is an equilateral triangle.

This technique of looking first to see whether a result holds in a special case is often useful.

To do this, consider an equilateral triangle $\triangle ABC$, with medians AP, BQ and CR. Since $\triangle ABC$ has sides of equal length, it must be symmetric about the line AP. Thus the point at which BQ meets CR must be symmetrically placed with respect to this line — that is, it must actually lie on the line AP. In other words, the lines AP, BQ and CR are concurrent if the triangle is equilateral.

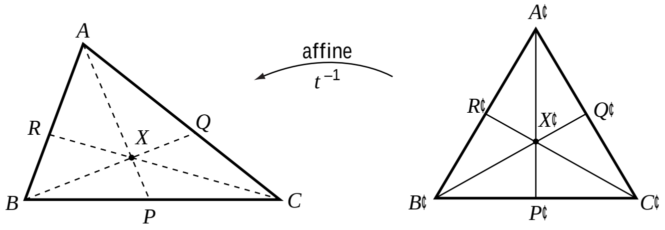


In order to show that the medians of an arbitrary triangle meet at a point, consider an arbitrary triangle $\triangle ABC$, and let P, Q and R be the midpoints of the sides BC, CA and AB, respectively. Next, choose a particular *equilateral* triangle $\triangle A'B'C'$, and let P', Q' and R' be the midpoints of the sides $B'C'$, $C'A'$ and $A'B'$, respectively.



According to the Fundamental Theorem of Affine Geometry there is an affine transformation t which maps $\triangle ABC$ onto $\triangle A'B'C'$. Moreover, since affine transformations preserve ratios of lengths along lines it follows that t maps the mid-points P, Q and R to the mid-points P', Q' and R', respectively.

From the above discussion we know that the medians of any *equilateral* triangle meet at a point, so in particular we know that $A'P'$, $B'Q'$ and $C'R'$ meet at some point X', say, as shown on the right below.



The trick now is to observe that t has an inverse t^{-1} which is also an affine transformation. This inverse maps the medians $A'P'$, $B'Q'$ and $C'R'$ back to the medians AP, BQ and CR of the original triangle $\triangle ABC$. Since X' lies on all three of the lines $A'P'$, $B'Q'$ and $C'R'$ it follows that t^{-1} maps X' to some point X which lies on all three of the lines AP, BQ and CR. In other words, the medians of $\triangle ABC$ are concurrent.

Since $\triangle ABC$ is an arbitrary triangle we have proved the Median Theorem.

The essence of the above proof is the fact that all triangles are affine-congruent. That powerful result enables us to prove theorems concerning the affine properties of triangles (such as collinearity, lines being parallel, and ratios of lengths along a given line) following a standard pattern. First, we choose a particular type of triangle for which it is easy to prove the result. Then, by asserting the existence of an affine transformation from that triangle to an arbitrary triangle, we deduce that the result holds for all triangles.

The basic affine properties were listed in Subsection 2.2.1.

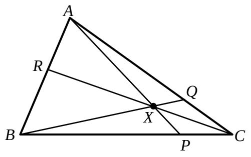
This is the approach we shall use to prove the theorems of Ceva and Menelaus later in the section.

2.4.2 Ceva's Theorem

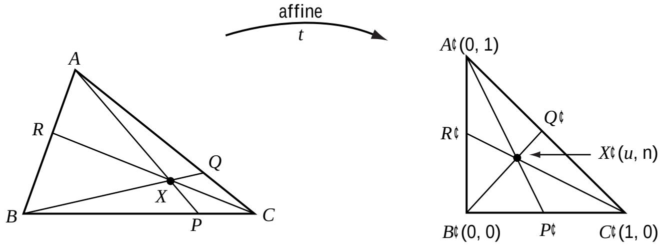
We now prove the following theorem due to Ceva.

Theorem 2 Ceva's Theorem
Let $\triangle ABC$ be a triangle, and let X be a point which does not lie on any of its (extended) sides. If AX meets BC at P, BX meets CA at Q and CX meets BA at R, then

$$\frac{AR}{RB} \cdot \frac{BP}{PC} \cdot \frac{CQ}{QA} = 1.$$



Proof According to the Fundamental Theorem of Affine Geometry there is an affine transformation t which maps the points A, B, C to the points $A' = (0,1)$, $B' = (0,0)$, $C' = (1,0)$, respectively. This transformation maps the triangle $\triangle ABC$ onto the right-angled triangle $\triangle A'B'C'$, and it maps the point X to some point $X' = (u, v)$.



Using coordinate geometry we can calculate the equations of the lines $A\ X$, $B\ X$, $C\ X$ and hence find the coordinates of the point P where $A\ X$ meets $B\ C$, of the point Q where $B\ X$ meets $A\ C$, and of the point R where $C\ X$ meets $A\ B$.

Starting with the point P, we note that the line $B\ C$ has equation $y = 0$.

Also, the line $A\ X$ has slope $\frac{1}{0\quad u}$, so its equation is $y \quad 1 = \frac{1}{0\quad u}(x \quad 0)$. Hence, at the point P where the two lines meet, we must have $y = 0$ and $y \quad 1 = \frac{1}{0\quad u}(x \quad 0)$, so

$$P = \frac{u}{1}, 0 \quad .$$

Similarly, at the point R we have $x = 0$, and $y \quad 0 = \frac{0}{1\quad u}(x \quad 1)$, so

$$R = 0, \frac{}{1 \quad u} \quad .$$

Finally, at Q we have $x + y = 1$ and $y = \frac{}{u}x$, so $x = \frac{u}{u+}$ and $y = \frac{}{u+}$. Hence

$$Q = \frac{u}{u+}, \frac{}{u+} \quad .$$

Thus, using the coordinate formulas for calculating ratios we obtain

These formulas are given at the beginning of Appendix 2 just above the Section Formula.

$$\frac{A\ R}{R\ B} = \frac{y_R \quad y_A}{y_B \quad y_R} = \frac{\frac{}{1\ u} \quad 1}{0 \quad \frac{}{1\ u}} = \frac{u + \quad 1}{},$$

$$\frac{B\ P}{P\ C} = \frac{x_P \quad x_B}{x_C \quad x_P} = \frac{\frac{u}{1} \quad 0}{1 \quad \frac{u}{1}} = \frac{u}{1 \quad u},$$

and

$$\frac{C\ Q}{Q\ A} = \frac{y_Q \quad y_C}{y_A \quad y_Q} = \frac{\frac{}{u+} \quad 0}{1 \quad \frac{}{u+}} = \frac{}{u}.$$

Hence

$$\frac{A\ R}{R\ B} \bullet \frac{B\ P}{P\ C} \bullet \frac{C\ Q}{Q\ A} = 1.$$

Since $t\ ^{1}$ is an affine transformation, it preserves ratios along a line. It must therefore map P, Q, R back to the points P, Q, R in such a way that

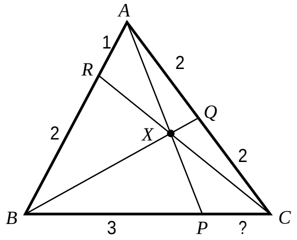
$$\frac{AR}{RB} \bullet \frac{BP}{PC} \bullet \frac{CQ}{QA} = 1,$$

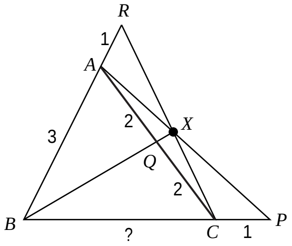
as required.

The next example illustrates how we can use Ceva's Theorem to calculate certain unknown distances along the sides of a triangle. For the method to work correctly, it is important to remember that all the ratios in Ceva's Theorem are *signed* ratios. Thus, if X lies inside the triangle, as in part (a) of the example, then all the ratios are positive. But if X lies outside the triangle, as in part (b), then two of the ratios will be negative.

Example 1

(a) In the figure on the left below, $AR = 1$, $RB = 2$, $BP = 3$, $CQ = 2$ and $QA = 2$. Calculate the distance PC.
(b) For the figure on the right, $AR = 1$, $AB = 3$, $PC = 1$, $CQ = 2$ and $QA = 2$. Calculate the distance BC.





Solution

(a) By Ceva's Theorem, we have

$$\frac{AR}{RB} \cdot \frac{BP}{PC} \cdot \frac{CQ}{QA} = 1;$$

so,

$$\frac{1}{2} \cdot \frac{3}{PC} \cdot \frac{2}{2} = 1.$$

It follows that $PC = \frac{3}{2}$.

(b) By Ceva's Theorem, we have

$$\frac{AR}{RB} \cdot \frac{BP}{PC} \cdot \frac{CQ}{QA} = 1;$$

so,

$$\frac{1}{4} \cdot \quad \frac{BC + 1}{1} \quad \cdot \frac{2}{2} = 1.$$

It follows that $BC = 3$. □

Problem 1

(a) Determine the ratio $\frac{BP}{PC}$ in the left diagram below, given that

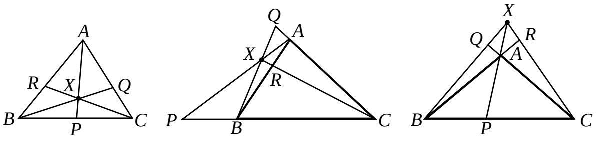
$$\frac{AR}{RB} = \frac{AQ}{QC} = \frac{3}{2}.$$

(b) Determine the ratio $\frac{CQ}{QA}$ in the middle diagram below, given that

$$\frac{AR}{RB} = \frac{1}{2} \quad \text{and} \quad \frac{BP}{PC} = \frac{2}{7}.$$

(c) Determine the ratio $\frac{AR}{RB}$ in the right diagram below, given that

$$\frac{BP}{PC} = \frac{5}{7} \quad \text{and} \quad \frac{CQ}{QA} = 7.$$



Ceva's Theorem has the following converse, which can be regarded as a generalization of the Median Theorem to configurations where P, Q, R are not all midpoints of sides.

Theorem 3 Converse to Ceva's Theorem
Let P, Q and R be points, other than vertices, on the (possibly extended) sides BC, CA and AB of a triangle $\triangle ABC$, such that

$$\frac{AR}{RB} \cdot \frac{BP}{PC} \cdot \frac{CQ}{QA} = 1. \tag{1}$$

Then the lines AP, BQ and CR are concurrent.

In the Median Theorem,

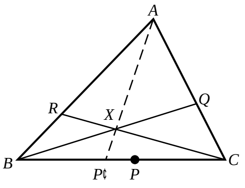
$$\frac{AR}{RB} = 1, \quad \frac{BP}{PC} = 1, \quad \frac{CQ}{QA} = 1,$$

so Theorem 3 generalizes the Median Theorem.

Proof Let the lines BQ and CR intersect at a point X, and let the line AX meet BC at some point P'. It is sufficient to prove that $P = P'$.

It follows from Ceva's Theorem that

$$\frac{AR}{RB} \cdot \frac{BP'}{P'C} \cdot \frac{CQ}{QA} = 1. \tag{2}$$



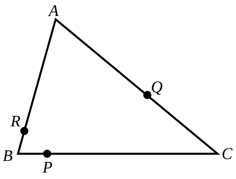
Hence, from equations (1) and (2), we have

$$\frac{BP}{PC} = \frac{BP'}{P'C},$$

so that P and P' must indeed be the same point.

Example 2 The triangle $\triangle ABC$ has vertices $A(1,3)$, $B(-1,0)$ and $C(4,0)$, and the points $P(0,0)$, $Q\left(\frac{8}{3}, \frac{4}{3}\right)$ and $R\left(-\frac{2}{3}, \frac{1}{2}\right)$ lie on BC, CA and AB, respectively.

(a) Determine the ratios in which P, Q and R divide the sides of the triangle.
(b) Determine whether the lines AP, BQ and CR are concurrent.



Solution

(a) Using the coordinate formulas for calculating ratios, we obtain

$$\frac{AR}{RB} = \frac{x_R - x_A}{x_B - x_R} = \frac{\frac{2}{3} - 1}{1 + \frac{2}{3}} = 5, \quad \frac{BP}{PC} = \frac{x_P - x_B}{x_C - x_P} = \frac{0 + 1}{4 - 0} = \frac{1}{4},$$

$$\frac{CQ}{QA} = \frac{x_Q - x_C}{x_A - x_Q} = \frac{\frac{8}{3} - 4}{1 - \frac{8}{3}} = \frac{4}{5}, \tag{3}$$

so that P divides BC in the ratio $1:4$, Q divides CA in the ratio $4:5$ and R divides AB in the ratio $5:1$.

(b) It follows from (3) that the product

$$\frac{AR}{RB} \cdot \frac{BP}{PC} \cdot \frac{CQ}{QA} = 5 \cdot \frac{1}{4} \cdot \frac{4}{5} = 1;$$

so by the converse to Ceva's Theorem the lines AP, BQ and CR must be concurrent. □

Problem 2 The triangle △ABC has vertices $A(-1,1)$, $B(2,-1)$ and $C(3,2)$, and the points $P\left(\frac{8}{3},1\right)$, $Q\left(2,\frac{7}{4}\right)$ and $R\left(\frac{4}{5},-\frac{1}{5}\right)$ lie on BC, CA and AB, respectively.

(a) Determine the ratios in which P, Q and R divide the sides of the triangle.

(b) Determine whether the lines AP, BQ and CR are concurrent.

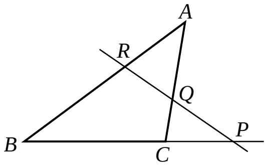
2.4.3 Menelaus' Theorem

Ceva's theorem is concerned with lines through the vertices of a triangle that meet at a point. We now use the Fundamental Theorem of Affine Geometry to prove an analogous theorem due to Menelaus which is concerned with points on the sides of a triangle that are collinear.

Theorem 4 Menelaus' Theorem

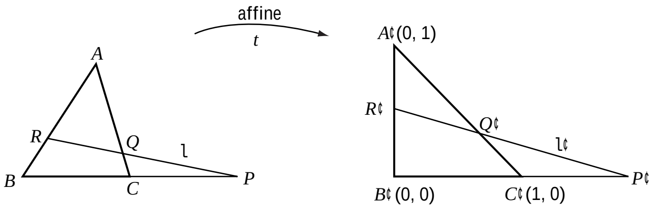
Let △ABC be a triangle, and let ℓ be a line that crosses the sides BC, CA, AB at three distinct points P, Q, R, respectively. Then

$$\frac{AR}{RB} \cdot \frac{BP}{PC} \cdot \frac{CQ}{QA} = -1.$$



Proof According to the Fundamental Theorem of Affine Geometry there is an affine transformation t which maps the points A, B, C to the points $A'(0,1)$, $B'(0,0)$, $C'(1,0)$, respectively. This transformation maps the triangle △ABC

onto the right-angled triangle $A'B'C'$, and it maps the line ℓ to some line ℓ'. Let the equation of ℓ' be $y = mx + c$.



We now calculate the coordinates of the points P', Q' and R' where ℓ' meets the sides $B'C'$, $C'A'$ and $A'B'$, respectively.

At P' we have $y = 0$ and $y = mx + c$. This implies that $x = -\frac{c}{m}$, and hence

$$P' = \left(-\frac{c}{m}, 0\right).$$

At R' we have $x = 0$ and $y = mx + c$. This implies that $y = c$, and hence

$$R' = (0, c).$$

At Q' we have $x + y = 1$ and $y = mx + c$. This implies that $1 - x = mx + c$ so that $x = \frac{1-c}{m+1}$; also $y = m(1 - y) + c$, so that $y = \frac{m+c}{m+1}$; and hence

$$Q' = \left(\frac{1-c}{m+1}, \frac{m+c}{m+1}\right).$$

Using the coordinate formulas for calculating ratios we obtain

$$\frac{A'R'}{R'B'} = \frac{y_{R'} - y_{A'}}{y_{B'} - y_{R'}} = \frac{c-1}{0-c} = -\frac{c-1}{c},$$

$$\frac{B'P'}{P'C'} = \frac{x_{P'} - x_{B'}}{x_{C'} - x_{P'}} = \frac{-\frac{c}{m} - 0}{1 + \frac{c}{m}} = -\frac{c}{m+c},$$

and

$$\frac{C'Q'}{Q'A'} = \frac{x_{Q'} - x_{C'}}{x_{A'} - x_{Q'}} = \frac{\frac{1-c}{m+1} - 1}{0 - \frac{1-c}{m+1}} = \frac{-(m+c)}{c-1}.$$

Hence,

$$\frac{A'R'}{R'B'} \cdot \frac{B'P'}{P'C'} \cdot \frac{C'Q'}{Q'A'} = -1.$$

Since t^{-1} is an affine transformation, it preserves ratios along a line. It must therefore map P', Q', R' back to the points P, Q, R in such a way that

$$\frac{AR}{RB} \cdot \frac{BP}{PC} \cdot \frac{CQ}{QA} = -1,$$

as required.

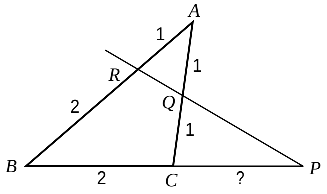
Remark

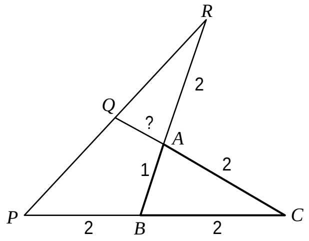
As for Ceva's Theorem, it is important to remember that all the ratios in Menelaus' Theorem are *signed* ratios. In fact if ℓ passes through the interior of the triangle, then precisely one of the ratios is negative; otherwise all the ratios are negative.

Example 3

(a) In the figure on the left below: $AR = 1$, $RB = 2$, $BC = 2$, $CQ = 1$ and $QA = 1$. Calculate the distance PC.

(b) In the figure on the right below: $AR = 2$, $AB = 1$, $BC = 2$, $CA = 2$ and $BP = 2$. Calculate the distance QA.





Solution

(a) By Menelaus' Theorem, we have

$$\frac{AR}{RB} \bullet \frac{BP}{PC} \bullet \frac{CQ}{QA} = 1.$$

So

$$\frac{1}{2} \bullet \frac{2+PC}{PC} \bullet \frac{1}{1} = 1.$$

It follows that $2 + PC = 2PC$, and hence $PC = 2$.

(b) By Menelaus' Theorem, we have

$$\frac{AR}{RB} \bullet \frac{BP}{PC} \bullet \frac{CQ}{QA} = 1.$$

So

$$\frac{2}{3} \cdot \frac{2}{4} \cdot \frac{2+QA}{QA} = 1.$$

It follows that $2 + QA = 3QA$, and hence $QA = 1$. □

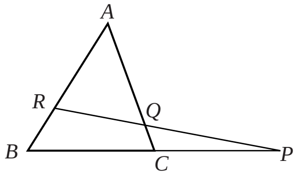
Problem 3

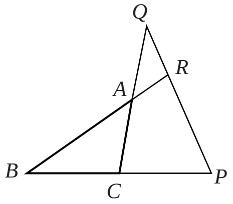
(a) Determine the ratio $\frac{CQ}{QA}$ in the left diagram below, given that

$$\frac{AR}{RB} = 2 \quad \text{and} \quad \frac{BP}{PC} = 2.$$

(b) Determine the ratio $\frac{CQ}{QA}$ in the right diagram below, given that

$$\frac{AR}{RB} = \frac{1}{4} \quad \text{and} \quad \frac{BP}{PC} = 2.$$





Menelaus Theorem has a converse that enables us to check whether points on the three sides of a triangle are collinear.

Theorem 5 Converse to Menelaus' Theorem
Let *P*, *Q* and *R* be points other than vertices on the (possibly extended) sides *BC*, *CA* and *AB* of a triangle *ABC*, such that

$$\frac{AR}{RB}\bullet\frac{BP}{PC}\bullet\frac{CQ}{QA} = 1. \tag{3}$$

Then the points *P*, *Q* and *R* are collinear.

Proof Let the line that passes through *Q* and *R* meet *BC* at some point *P* . It is sufficient to prove that $P = P$.

It follows from Menelaus Theorem that

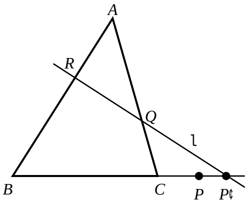
$$\frac{AR}{RB}\bullet\frac{BP}{P\ C}\bullet\frac{CQ}{QA} = 1. \tag{4}$$

Hence, from equations (3) and (4) we deduce that

$$\frac{BP}{PC} = \frac{BP}{P\ C}.$$

It follows that *P* and *P* must indeed be the same point.

The strategy of the proof is the same as that of Theorem 3.



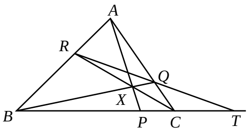
Problem 4 The triangle *ABC* has vertices $A(2,4)$, $B(\ 2,0)$ and $C(1,0)$, and the points $P\ \frac{5}{2},0$, $Q\ \frac{3}{2},2$ and $R(1,3)$ lie on *BC*, *CA* and *AB*, respectively.

(a) Determine the ratios in which *P*, *Q* and *R* divide the sides of the triangle.
(b) Hence determine whether the points *P*, *Q* and *R* are collinear.

We end this subsection with two revision problems.

Problem 5 Let *ABC* be a triangle, and let *X* be a point which does not lie on any of its (extended) sides. Also, let *AX* meet *BC* at *P*, *BX* meet *CA* at *Q* and *CX* meet *BA* at *R*; and let *QR* and *BC* meet at *T*.

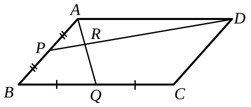
Given that $\frac{BP}{PC} = k$, determine $\frac{BT}{TC}$ in terms of *k*.



Problem 6 Suppose that P and Q are the midpoints of the sides AB and BC of a parallelogram $ABCD$, and that the lines DP and AQ meet at R.

(a) Determine the image of B under the affine transformation t which maps A, D and C to (0, 1), (0, 0) and (1, 0), respectively.

(b) By considering the image of $ABCD$ under t, determine the ratios $PR : RD$ and $AR : RQ$.



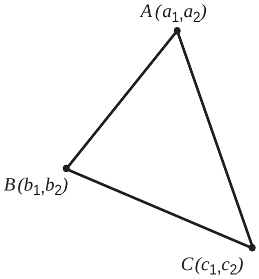
2.4.4 Barycentric Coordinates

In this subsection we introduce a new coordinate system, of *barycentric coordinates* with respect to a *triangle of reference*, for points in the plane, which can simplify some calculations. Rather than use two perpendicular axes to determine the coordinates of an arbitrary point in the plane, we use a weighted sum of the coordinates of three non-collinear points the vertices of the triangle of reference.

Barycentric coordinates were introduced by Möbius in 1827.

Definitions Let $A = (a_1, a_2)$, $B = (b_1, b_2)$ and $C = (c_1, c_2)$ be three non-collinear points in the plane $\mathbb{R}^2$; we will call ABC the **triangle of reference**. Then a point (x, y) in the plane has **barycentric coordinates** $(\ , \ , \ )$ with respect to ABC if

$$\begin{aligned} x &= \ a_1 + \ b_1 + \ c_1, \\ y &= \ a_2 + \ b_2 + \ c_2, \text{ and} \\ 1 &= \quad + \quad + \quad . \end{aligned} \tag{5}$$



Remark

In particular, notice that the barycentric coordinates of the vertices A, B and C of the triangle of reference ABC are (1,0,0), (0,1,0) and (0,0,1), respectively.

Thus, for example, if the triangle of reference ABC has vertices $A = (1, 2)$, $B = (\ 3, 0)$ and $C = (\ 2, 4)$, then the point with barycentric coordinates $\frac{1}{2}, \frac{3}{4}, \ \frac{1}{4}$ has cartesian coordinates

Cartesian coordinates are the standard Euclidean coordinates in the plane.

$$\begin{aligned} &\tfrac{1}{2} \bullet (1) + \tfrac{3}{4} \bullet (\ 3) \quad \tfrac{1}{4} \bullet (\ 2), \tfrac{1}{2} \bullet (2) + \tfrac{3}{4} \bullet (0) \quad \tfrac{1}{4} \bullet 4 \\ &= \frac{2 \quad 9 + 2}{4}, \frac{4 + 0 \quad 4}{4} \\ &= \ \tfrac{5}{4}, 0 \ . \end{aligned}$$

We may express the formula (5) for barycentric coordinates in terms of matrices in the form

$$\begin{matrix} x \\ y \\ 1 \end{matrix} = \mathbf{M} \qquad , \quad \text{where } \mathbf{M} = \begin{matrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ 1 & 1 & 1 \end{matrix} . \tag{6}$$

Since $A = (a_1, a_2)$, $B = (b_1, b_2)$ and $C = (c_1, c_2)$ are non-collinear, the determinant $\det \mathbf{M}$ is non-zero. Then, since $\mathbf{M}$ is non-singular, we can reformulate the representation (6) as

We do not prove that $\det \mathbf{M} = 0$ here.

$$= \mathbf{M}^{\ 1} \begin{matrix} x \\ y \\ 1 \end{matrix} . \tag{7}$$

Example 4 Determine barycentric coordinates for the point (2,1) with respect to the triangle of reference ABC where $A = (1, 0)$, $B = (1,\ \ 1)$ and $C = (\ \ 1, 1)$.

Solution The matrix $\mathbf{M}$ for the triangle of reference ABC is

$$\mathbf{M} = \begin{matrix} 1 & 1 & 1 \\ 0 & 1 & 1 \\ 1 & 1 & 1 \end{matrix} ,$$

whose inverse is

We omit the details of the calculation of this inverse.

$$\begin{matrix} 1 & 1 & 0 \\ \frac{1}{2} & 1 & \frac{1}{2} \\ \frac{1}{2} & 0 & \frac{1}{2} \end{matrix} .$$

It follows from the representation (7) that the point (2,1) has barycentric coordinates with respect to the triangle of reference ABC given by

$$\begin{matrix} 1 & 1 & 0 \\ \frac{1}{2} & 1 & \frac{1}{2} \\ \frac{1}{2} & 0 & \frac{1}{2} \end{matrix} \begin{matrix} 2 \\ 1 \\ 1 \end{matrix} = \begin{matrix} 3 \\ \frac{3}{2} \\ \frac{1}{2} \end{matrix} ;$$

namely, barycentric coordinates $3,\ \ \frac{3}{2},\ \ \frac{1}{2}$. □

Problem 7 Determine barycentric coordinates for the point $(\ \ 1, 1)$ with respect to the triangle of reference ABC where $A = (1, 1)$, $B = (2, 2)$ and $C = (1, 2)$.

Next, we give barycentric versions of the condition for collinearity of three points in the plane and of the equation of a line in the plane.

Theorem 6 The points P, Q and R with barycentric coordinates $({}_1, {}_1, {}_1)$, $({}_2, {}_2, {}_2)$ and $({}_3, {}_3, {}_3)$ are collinear if and only if

$$\begin{matrix} {}_1 & {}_2 & {}_3 \\ {}_1 & {}_2 & {}_2 \\ {}_1 & {}_2 & {}_3 \end{matrix} = 0.$$

Proof Let the points P, Q and R have cartesian coordinates (x_1, y_1), (x_2, y_2) and (x_3, y_3), respectively. It follows that, if the triangle of reference ABC has vertices $A = (a_1, a_2)$, $B = (b_1, b_2)$ and $C = (c_1, c_2)$, then we may apply the formula (5) to each of P, Q and R in turn to obtain

$$x_1 = a_1 {}_1 + b_1 {}_1 + c_1 {}_1 \text{ and } y_1 = a_2 {}_1 + b_2 {}_1 + c_2 {}_1,$$

$$x_2 = a_1 {}_2 + b_1 {}_2 + c_1 {}_2 \text{ and } y_2 = a_2 {}_2 + b_2 {}_2 + c_2 {}_2,$$

$$x_3 = a_1 {}_3 + b_1 {}_3 + c_1 {}_3 \text{ and } y_3 = a_2 {}_3 + b_2 {}_3 + c_2 {}_3.$$

We may write these simultaneous equations in matrix form as

$$\begin{matrix} x_1 & x_2 & x_3 \\ y_1 & y_2 & y_3 \\ 1 & 1 & 1 \end{matrix} = \begin{matrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ 1 & 1 & 1 \end{matrix} \begin{matrix} {}_1 & {}_2 & {}_3 \\ {}_1 & {}_2 & {}_3 \\ {}_1 & {}_2 & {}_3 \end{matrix}$$

$$= \mathbf{M} \begin{matrix} {}_1 & {}_2 & {}_3 \\ {}_1 & {}_2 & {}_3 \\ {}_1 & {}_2 & {}_3 \end{matrix}, \qquad (8)$$

The results for P, Q and R are set out as columns 1, 2 and 3, respectively, of the left-hand matrix.

where $\mathbf{M} = \begin{matrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ 1 & 1 & 1 \end{matrix}$.

Now, **M** is non-singular since the points A, B and C are non-collinear. Then it follows from equation (8) that

$$\begin{matrix} {}_1 & {}_2 & {}_3 \\ {}_1 & {}_2 & {}_3 \\ {}_1 & {}_2 & {}_3 \end{matrix} = 0 \text{ if and only if } \begin{matrix} x_1 & x_2 & x_3 \\ y_1 & y_2 & y_3 \\ 1 & 1 & 1 \end{matrix} = 0.$$

But the second determinant equation here is the condition for P, Q and R to be collinear. The desired result then follows immediately.

Corollary The line through the points with barycentric coordinates $({}_1, {}_1, {}_1)$ and $({}_2, {}_2, {}_2)$ has equation

$$\begin{matrix} {}_1 & {}_2 \\ {}_1 & {}_2 \\ {}_1 & {}_2 \end{matrix} = 0.$$

That is, an equation in terms of barycentric coordinates.

For example, if the triangle of reference is *ABC*, the equation of the line *AB* in terms of barycentric coordinates is

$$\begin{matrix} 1 & 0 & \\ 0 & 1 & \\ 0 & 0 & \end{matrix} \quad = 0;$$

which simplifies to the equation $= 0$.

Similarly, *BC* and CA have equations $= 0$ and $= 0$.

Problem 8 Determine which of the following sets of points, described by their barycentric coordinates with respect to an unspecified triangle of reference, are collinear; for those that are collinear, determine the equation of the line on which they lie.

(a) $(1, 1, \quad 1), (4, \quad 2, \quad 1), \quad \frac{1}{2}, 2, \quad \frac{3}{2}$

(b) $(1, 1, \quad 1), (2, \quad 2, 1), (\quad 1, 7, \quad 5)$

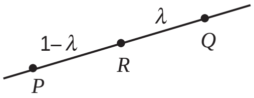
Next, we meet a version of the Section Formula in terms of barycentric coordinates.

The Section Formula is given in Appendix 2.

Theorem 7 Section Formula

The point *R* that divides the line joining the points *P* and *Q* with barycentric coordinates $({}_1, {}_1, {}_1)$ and $({}_2, {}_2, {}_2)$ in the ratio $(1 \quad) : \quad$ has barycentric coordinates

$$(\ , \ , \ ) = \ ({}_1, {}_1, {}_1) + (1 \quad)({}_2, {}_2, {}_2).$$



Proof Let *P*, *Q* and *R* have cartesian coordinates (x_1, y_1), (x_2, y_2) and (x, y), respectively. It follows from the cartesian form of the Section Formula that

$$(x, y) = \ (x_1, y_1) + (1 \quad)(x_2, y_2), \quad \text{for some real number} \quad ;$$

we can rewrite this equation in matrix form as

$$\begin{matrix} x \\ y \\ 1 \end{matrix} = \ \begin{matrix} x_1 \\ y_1 \\ 1 \end{matrix} + (1 \quad) \begin{matrix} x_2 \\ y_2 \\ 1 \end{matrix} .$$

Multiplying both sides of this equation on the left by the matrix $\mathbf{M}^{\ 1}$ and using the formula (8), it follows that

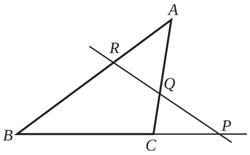
$$= \ \begin{matrix} {}_1 \\ {}_1 \\ {}_1 \end{matrix} + (1 \quad) \begin{matrix} {}_2 \\ {}_2 \\ {}_2 \end{matrix} .$$

This is the desired result.

We can now use barycentric coordinate methods to give further proofs of Menelaus s Theorem and Ceva s Theorem.

Theorem 8 Menelaus' Theorem
Let ABC be a triangle, and let be a line that crosses the sides *BC*, *CA* and *AB* at three distinct points *P*, *Q*, *R*, respectively. Then

$$\frac{AR}{RB} \cdot \frac{BP}{PC} \cdot \frac{CQ}{QA} = \quad 1.$$



Proof Define , μ and as follows:

$$\frac{BP}{PC} = \frac{1 \quad}{\quad}, \quad \frac{CQ}{QA} = \frac{1 \quad \mu}{\mu}, \quad \frac{AR}{RB} = \frac{1 \quad}{\quad}.$$

Hence, by the Section Formula, P has barycentric coordinates

$$\begin{aligned} P &= \quad (0,1,0) + (1 \quad\ )(0,0,1) \\ &= (0, \ , 1 \quad\ ). \end{aligned}$$

For, P divides BC in the ratio (1) : .

Similarly, Q and R have barycentric coordinates $(1 \quad \mu, 0, \mu)$ and $(\ , 1 \ , 0)$, respectively.

Then, by Theorem 6 the points P, Q and R are collinear if and only if

We omit the details of these calculations.

$$\begin{matrix} 0 & 1 \quad \mu & \\ & 0 & 1 \\ 1 & \mu & 0 \end{matrix} = 0.$$

Expanding this determinant, we have that P, Q and R are collinear if and only if

$$(1 \quad \mu) \begin{matrix} & 1 \\ 1 & 0 \end{matrix} + \begin{matrix} & 0 \\ 1 & \mu \end{matrix} = 0;$$

that is, if and only if

$$(1 \quad\ )(1 \quad \mu)(1 \quad\ ) + \quad \mu \quad = 0,$$

or

$$\frac{1 \quad}{\quad} \cdot \frac{1 \quad \mu}{\mu} \cdot \frac{1 \quad}{\quad} = \quad 1.$$

From the original definition of , μ and , it follows that P, Q and R are collinear if and only if

$$\frac{AR}{RB} \cdot \frac{BP}{PC} \cdot \frac{CQ}{QA} = \quad 1.$$

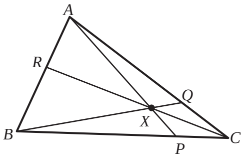
From our assumption that P, Q and R are collinear, the desired result follows.

Notice that we have also obtained a proof of the converse of Menelaus Theorem, since this equality is an if and only if result!

Theorem 9 Ceva's Theorem

Let *ABC* be a triangle, and let *X* be a point which does not lie on any of its (extended) sides. If *AX* meets *BC* at *P*, *BX* meets *CA* at Q and *CX* meets *BA* at *R*, then

$$\frac{AR}{RB} \bullet \frac{BP}{PC} \bullet \frac{CQ}{QA} = 1.$$



Proof We use the same notation , μ and as in the previous proof, so that again *P*, *Q* and *R* have homogeneous coordinates $(0,\ ,1\quad)$, $(1\quad\mu,0,\mu)$ and $(\ ,1\quad,0)$, respectively.

Then, using the Corollary to Theorem 6 the equation of *AP* is

$$\begin{matrix} 1 & & 0 \\ 0 & & \\ 0 & 1 & \end{matrix} = 0,$$

which simplifies to

$$\frac{\quad}{1\quad} = 0.$$

This gives that the equation of *AP* is $\ (1\quad)\ = 0$, or

$$= \frac{1}{\quad}.$$

Similarly, we find that the equation of *BQ* is $= \frac{1\ \ \mu}{\mu}$.

Since *AP* and *BQ* meet at *X*, it follows that the barycentric coordinates $(\ ,\ ,\ )$ of *X* must satisfy the equations $= \frac{1}{\quad}$ and $= \frac{1\ \ \mu}{\mu}$; hence its barycentric coordinates are

We omit the details of this calculation.

$$\frac{1}{\quad} \bullet \frac{1\quad\mu}{\mu}\ ,\ ,\ \frac{1}{\quad}\ ,\quad \text{for some}\ = 0.$$

Then *C*, *X* and *R* are collinear if and only if

$$\begin{matrix} 0 & \frac{1}{\quad} \bullet \frac{1\quad\mu}{\mu} & \\ 0 & & 1 \\ 1 & \frac{1}{\quad} & 0 \end{matrix} = 0;$$

this simplifies to

$$\frac{1}{\quad} \bullet \frac{1\quad\mu}{\mu} \bullet \frac{1}{\quad} = 1.$$

It follows that C, X and R are collinear — that is, that AP, BQ and CR are concurrent — if and only if

$$\frac{AR}{RB} \cdot \frac{BP}{PC} \cdot \frac{CQ}{QA} = 1.$$

From our assumption that AP, BQ and CR are concurrent, the desired result follows.

Notice that we have also obtained a proof of the converse of Ceva's Theorem, since this equality is an 'if and only if' result!

2.5 Affine Transformations and Conics

2.5.1 Classifying Non-Degenerate Conics in Affine Geometry

In Section 2.2 you saw that under an affine transformation a straight line maps to a straight line. Indeed, it follows from the Fundamental Theorem of Affine Geometry that any straight line can be mapped to any other straight line by some affine transformation. We now explore the corresponding situation for conics.

We discussed conics in Chapter 1.

Recall that a conic is a set in $\mathbb{R}^2$ given by an equation of the form

$$Ax^2 + Bxy + Cy^2 + Fx + Gy + H = 0, \qquad (1)$$

where A, B, C, F, G and H are real numbers, and A, B and C are not all zero. The three types of non-degenerate conic are ellipses, parabolas and hyperbolas. A non-degenerate conic is an ellipse if $B^2 - 4AC < 0$, a parabola if $B^2 - 4AC = 0$, and a hyperbola if $B^2 - 4AC > 0$.

You met the $B^2 - 4AC$ test for conics in Theorem 3 of Section 1.3.

First, consider the case where equation (1) represents an ellipse, as illustrated on the left of the figure below. We can apply a translation to move the centre of the ellipse to the origin, and then a rotation to align its major and minor axes with the directions of the x-axis and y-axis, respectively. After we have applied these two Euclidean transformations, the equation of the ellipse becomes

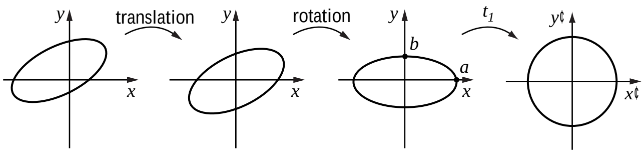
$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1, \quad a \geq b > 0. \qquad (2)$$

If we now apply the affine transformation $t_1 : (x, y) \mapsto (x', y')$, where

$$\begin{pmatrix} x' \\ y' \end{pmatrix} = \begin{pmatrix} 1/a & 0 \\ 0 & 1/b \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix},$$

then $x' = x/a$ and $y' = y/b$, so equation (2) becomes

$$(x')^2 + (y')^2 = 1.$$



Since the translation, the rotation and the transformation t_1 are all affine, their composite must also be affine. Overall, this shows that each ellipse can be mapped onto the unit circle by an affine transformation. We therefore have the following theorem.

Theorem 1 Every ellipse is affine-congruent to the unit circle with equation $x^2 + y^2 = 1$.

Secondly, consider the case where equation (1) represents a hyperbola, as illustrated on the left of the figure below. Again, we can apply a translation to move the centre of the hyperbola to the origin, and then a rotation to align its major and minor axes with the directions of the x-axis and y-axis, respectively. After we have applied these two transformations, the equation of the hyperbola becomes

$$\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1. \tag{3}$$

Under the affine transformation t_1 defined above, equation (3) becomes

$$(x')^2 - (y')^2 = 1,$$

that is,

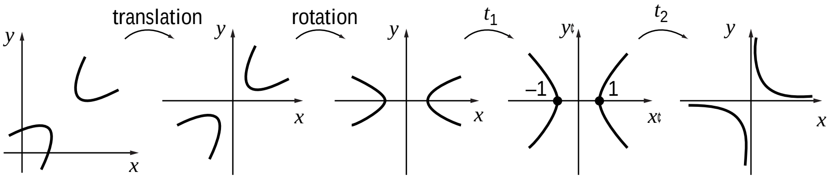
$$(x' - y')(x' + y') = 1. \tag{4}$$

Finally, if we apply the affine transformation $t_2 : (x', y') \mapsto (x'', y'')$, where

$$\begin{pmatrix} x'' \\ y'' \end{pmatrix} = \begin{pmatrix} 1 & -1 \\ 1 & 1 \end{pmatrix} \begin{pmatrix} x' \\ y' \end{pmatrix},$$

then equation (4) becomes

$$x''y'' = 1.$$



Dropping the dashes from the equation $x''y'' = 1$, we obtain the following theorem.

Theorem 2 Every hyperbola is affine-congruent to the rectangular hyperbola with equation $xy = 1$.

Recall that 'rectangular' means that the asymptotes of the hyperbola are at right angles to each other.

Finally, consider the case where equation (1) represents a parabola, as illustrated on the left of the figure below. We can apply a translation to move the vertex of the parabola to the origin, and then a rotation to align its axis with the (positive) x-axis. After we have applied these two Euclidean transformations, the equation of the parabola becomes

$$y^2 = ax, \tag{5}$$

where a is some positive number which depends on the coefficients in equation (1).

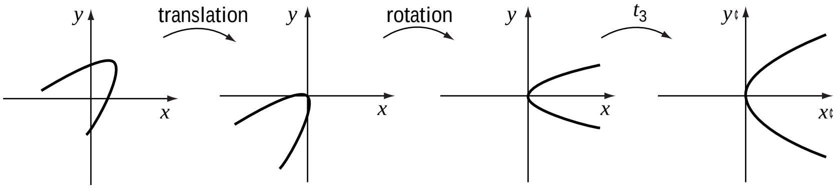
Here we omit the details of the particular transformations involved, and concentrate instead on the principles underlying the successive mappings which are used.

Next, if we apply the affine transformation $t_3 : (x, y) \mapsto (x', y')$, where

$$\begin{pmatrix} x' \\ y' \end{pmatrix} = \begin{pmatrix} 1/a & 0 \\ 0 & 1/a \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix},$$

then $x' = x/a$ and $y' = y/a$, so equation (5) becomes $(y'a)^2 = a(x'a)$, or

$$(y')^2 = x'.$$



Dropping the dashes, we obtain the following theorem.

Theorem 3 Every parabola is affine-congruent to the parabola with equation $y^2 = x$.

Since all parabolas are affine-congruent to $y^2 = x$, they must be affine-congruent to each other. Similarly, by Theorem 1, all ellipses must be affine-congruent to each other; and, by Theorem 2, all hyperbolas must be affine-congruent to each other.

This raises the question as to whether it is possible for one type of conic (such as an ellipse) to be affine-congruent to another type of conic (such as a hyperbola). The next theorem shows that this cannot happen. In fact, since an affine transformation can be expressed as the composite of two parallel projections, this should not surprise you. After all, no parallel projection can change a bounded curve (such as an ellipse) into an unbounded one (such as a parabola or a hyperbola); nor can it change a curve with two branches (a hyperbola) into a curve with just one branch (an ellipse or a parabola).

Theorem 4 Affine transformations map ellipses to ellipses, parabolas to parabolas, and hyperbolas to hyperbolas.

Remember that a circle is a special type of ellipse.

Proof Consider the non-degenerate conic with equation

$$Ax^2 + Bxy + Cy^2 + Fx + Gy + H = 0, \tag{6}$$

and its image under an affine transformation $t : \mathbf{x} \mapsto \mathbf{x}'$ given by

$$\mathbf{x}' = \mathbf{A}\mathbf{x} + \mathbf{b},$$

where $\mathbf{A}$ is an invertible 2 × 2 matrix.

The inverse affine transformation $t^{-1} : \mathbf{x}' \mapsto \mathbf{x}$ is given by

$$\mathbf{x} = \mathbf{A}^{-1}\mathbf{x}' - \mathbf{A}^{-1}\mathbf{b},$$

You met this formula for the inverse in Subsection 2.2.1.

which we may write in the form

$$\begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} p & q \\ r & s \end{pmatrix} \begin{pmatrix} x' \\ y' \end{pmatrix} + \begin{pmatrix} u \\ v \end{pmatrix},$$

for some real numbers p, q, r, s, u and v. It follows that

$$x = px' + qy' + u \quad \text{and} \quad y = rx' + sy' + v. \tag{7}$$

If we now substitute these expressions for x and y into equation (6), then the resulting equation is a second-degree equation in x' and y', so the image of the conic under the affine transformation t must be another conic.

We omit the details of these calculations, as they are complicated and uninformative.

Next we show that this image conic cannot be degenerate. A degenerate image would consist of a pair of lines, a single line, a point, or the empty set. Since the affine transformation t^{-1} maps lines to lines, it would map the degenerate image to another degenerate conic. But this cannot happen since t^{-1} maps the image back to the original non-degenerate conic (6). It follows that the image of (6) cannot be degenerate.

Theorem 2 of Section 2.3

Finally, if we substitute for x and y from equations (7) into equation (6), and keep careful track of the algebra involved, it turns out that the discriminant of the image conic is just

$$(ps - rq)^2(B^2 - 4AC).$$

Recall that the sign of the discriminant of a non-degenerate conic determines the type of the conic.

Here $B^2 - 4AC$ is the discriminant of the original conic. Since $(ps - rq)^2 > 0$, the sign of the discriminant is not changed by an affine transformation of a conic. Hence the type of the conic is also unchanged.

Here $ps - rq = 0$ since $\mathbf{A}$ is invertible.

We can combine the results of Theorems 1–4 to obtain the following corollary.

Corollary In affine geometry:

(a) all ellipses are congruent to each other;
(b) all hyperbolas are congruent to each other;
(c) all parabolas are congruent to each other.

Non-degenerate conics are congruent only to non-degenerate conics of the same type.

The corollary shows that affine-congruence partitions the set of non-degenerate conics into three disjoint equivalence classes. One class consists of all the ellipses, another class consists of all the hyperbolas, and the third consists of all the parabolas. Each class contains one of the so-called *standard* conics $x^2 + y^2 = 1$, $xy = 1$ and $y^2 = x$.

Just as the Fundamental Theorem of Affine Geometry enables us to deduce a given result about an arbitrary triangle by showing that the result holds for an equilateral triangle, so the corollary enables us to deduce a given result about an arbitrary ellipse, hyperbola or parabola by showing that the result holds for the corresponding standard conic. Of course, this works only if the result is concerned with the affine properties of the conic, so we need to be able to recognize such properties.

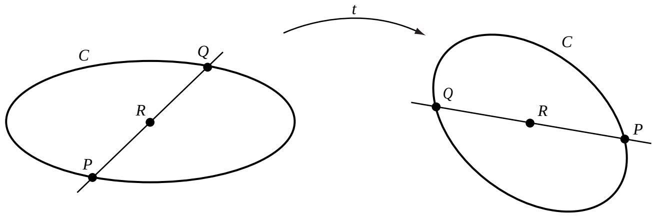
The following theorem shows that one such property is the property of being the centre of an ellipse or hyperbola.

Theorem 5 Let t be an affine transformation, and let C be an ellipse or hyperbola with centre R. Then $t(C)$ has centre $t(R)$.

Recall that a parabola does not have a centre.

Proof Let C' and R' be the images of C and R under t. If P' is any point on C', then it must be the image of some point P on C. Since R is the centre of C, we can rotate P about R through an angle π to a point Q which must also lie on C. Hence $Q' = t(Q)$ is a point on C'.

This uses the definition of centre given in Chapter 1.



This figure illustrates the proof for an ellipse C, but the proof works equally well for a hyperbola.

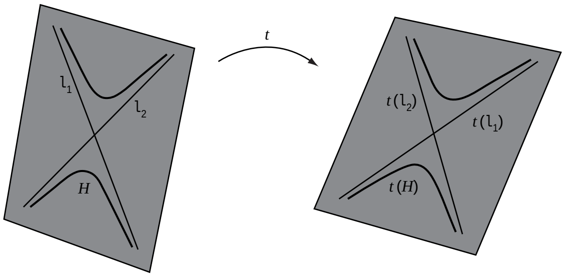
Now t preserves ratios of lengths along lines, so the line segment PRQ maps onto the line segment $P'R'Q'$ with $P'R' = R'Q'$. Thus if we rotate P' about R' through an angle π, it must go to Q' on C'. Now, as our choice for P' as a point on C' varies, so do $P = t^{-1}(P')$ and Q, but the point R is always the same point. It follows that the midpoint of $P'Q'$ is always the same point $R' = t(R)$. Hence $R' = t(R)$ is the centre of C', as required.

For since $PR/RQ = 1$ it follows that $P'R'/R'Q' = 1$.

Another affine property is the property of being an asymptote of a hyperbola.

Theorem 6 Let t be an affine transformation, and let H be a hyperbola with asymptotes ℓ_1 and ℓ_2. Then $t(H)$ has asymptotes $t(\ell_1)$ and $t(\ell_2)$.

The figure below illustrates that this theorem is plausible for parallel projections.



Proof The hyperbola H possesses exactly two (distinct) families of parallel lines each of which fills the plane, with each member of each family meeting H exactly once apart from one line in each family that is an asymptote of H, and so does not meet H.

The image of H under the affine transformation t is also a hyperbola, $t(H)$. The images under t of the two families of parallel lines are also (distinct) families of parallel lines; within each family, a line that meets H once is mapped onto a line that meets $t(H)$ once, and the single line that does not meet H maps onto a line that does not meet $t(H)$. So the two exceptional lines in the image families must be the asymptotes of the hyperbola $t(H)$.

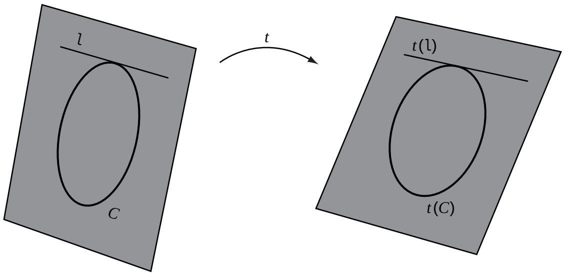
It follows that the asymptotes of H are mapped by t to the asymptotes of $t(H)$, as required.

Many of the problems concerning conics which are particularly amenable to solution using the methods of affine geometry involve tangents.

This is due to the following theorem, which asserts that tangency is an affine property.

Theorem 7 Let t be an affine transformation, and let be a tangent to a conic C. Then $t(\ )$ is a tangent to the conic $t(C)$.

The figure below illustrates the theorem for parallel projections.



Solution We shall use the fact that a tangent to a conic (whether it is an ellipse, a hyperbola or a parabola) intersects the conic at exactly one point.

However we have to be a little careful. For example, any line parallel to its axis meets a parabola in exactly one point.

First, the image of an ellipse E under an affine transformation t is an ellipse. A tangent to E is a line that intersects E in exactly one point. These properties remain unchanged under an affine projection; hence the image of a tangent to E under an affine transformation t must be a tangent to $t(E)$.

This characterizes tangents to ellipses.

Next, the image of a hyperbola H under an affine transformation t is a hyperbola. A tangent to H is a member of a family of parallel lines that fill the plane such that there are lines in the family that meet H twice, once and not at all; there are exactly two lines in the family that meet H exactly once, and these are tangents to H. The image of the family of lines under t is again a family of parallel lines that fill the plane; it contains lines that meet the parabola $t(H)$ twice and not at all, and exactly two lines that meet H exactly once. These lines are the images of the original tangents to H, and must themselves be tangents to $t(H)$. Hence, the image of a tangent to H under an affine transformation t must be a tangent to $t(H)$.

This characterizes tangents to hyperbolas.

Finally, the image of a parabola P under an affine transformation t is a parabola. A tangent to P is a member of a family of parallel lines that fill the plane such that there are lines in the family that meet P twice, once and not at all; the tangent is the unique member of the family that meets P exactly once. The image of the family of lines under t is again a family of parallel lines that fill the plane; it contains lines that meet the parabola $t(P)$ twice and not at all, and a single line that meets P exactly once. This line is the image of the original tangent to P, and must itself be a tangent to $t(P)$. Hence, the image of a tangent to P under an affine transformation t must be a tangent to $t(P)$.

This characterizes tangents to parabolas.

This completes the proof.

In applications we often use the following facts that you met earlier.

Theorem 2, Subsection 1.2.1.

Tangents to Conics in Standard Form The equation of the tangent to a standard conic at the point (x_1, y_1) is as follows.

Conic	*Tangent*
Unit circle $x^2 + y^2 = 1$	$xx_1 + yy_1 = 1$
Rectangular hyperbola $xy = 1$	$xy_1 + yx_1 = 2$
Parabola $y^2 = x$	$2yy_1 = x + x_1$

2.5.2 Applying Affine Geometry to Conics

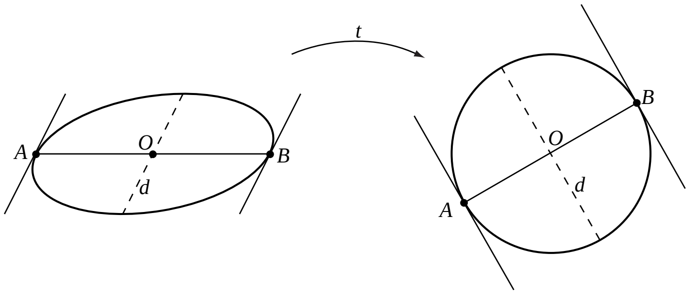
We are now in a position to apply the methods of affine geometry to the solution of problems involving conics. Of course, affine geometry can be helpful in this task only if the property being investigated is one which is preserved under affine transformations. The underlying idea is that we use an affine transformation to map the original conic onto one of our standard conics, tackle the problem in hand there, and then map back to the original conic.

We used these techniques in Subsection 2.2.3 to prove the Conjugate Diameters Theorem for the ellipse.

Example 1 *AB* is a diameter of an ellipse. Prove that the tangents to the ellipse at *A* and *B* are parallel to the diameter conjugate to *AB*.

Recall that the diameter conjugate to *AB* is the set of midpoints of all the chords parallel to *AB* (see Subsection 2.2.3).

Solution First, map the ellipse onto the unit circle, by an affine transformation *t*. Since the centre *O* of the ellipse maps to the centre O' of the circle, the image of the diameter *AB* is a diameter $A'B'$ of the unit circle.

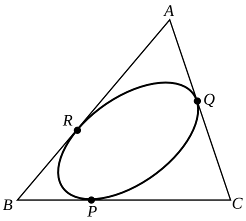


All chords of the circle that are parallel to the tangents at A' and B' are bisected by $A'B'$, and so the diameter through O' is the diameter conjugate to $A'B'$. Since parallel lines map to parallel lines and ratios along parallel lines are preserved under the inverse affine transformation t^{-1}, it follows that all chords of the ellipse that are parallel to the tangents at *A* and *B* are bisected by *AB*, and so the diameter through *O* that is parallel to the tangents at *A* and *B* is the diameter conjugate to *AB*. □

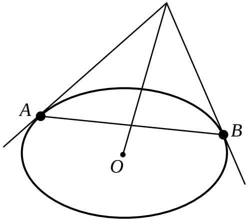
Problem 1 An ellipse touches the sides *BC*, *CA* and *AB* of $\triangle ABC$ at the points *P*, *Q* and *R*, respectively. Prove that

$$\frac{AR}{RB} \cdot \frac{BP}{PC} \cdot \frac{CQ}{QA} = 1,$$

and deduce that the lines *AP*, *BQ* and *CR* are concurrent.



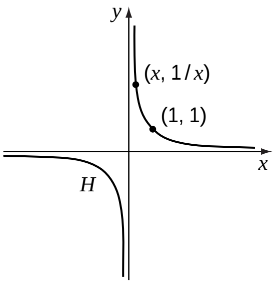
Problem 2 The tangents to an ellipse at two points *A* and *B* meet at a point *T*. Prove that the line joining *T* to the centre *O* of the ellipse bisects the chord *AB*.



The rectangular hyperbola $H = \{(x, y) : xy = 1\}$ does not possess as much symmetry as does the unit circle; so the fact that every hyperbola is affine-congruent to *H* may not be sufficient to simplify a given problem. Fortunately, however, we can also arrange for any given point on the original hyperbola to map to the point (1, 1) on *H*.

To see this, note that for any non-zero number a, the affine transformation

$$t_a : \begin{pmatrix} x \\ y \end{pmatrix} \mapsto \begin{pmatrix} a & 0 \\ 0 & 1/a \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix}$$

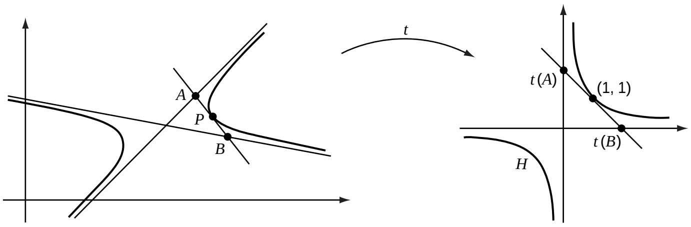


maps H to itself. For, an arbitrary point on H has coordinates of the form $(x, 1/x)$, $x \neq 0$, and under t_a this is mapped to the point $(ax, 1/ax)$, which also lies on H. As x varies through $\mathbb{R} - \{0\}$, its image $(ax, 1/ax)$ varies over the whole of H, so the image of H under t_a is the whole of H.

So if we start with a given hyperbola and a point P on it, we can map the hyperbola to H by some affine transformation s. The point $s(P)$ will then have coordinates $(b, 1/b)$ for some number $b \in \mathbb{R} - \{0\}$; so if we choose $a = 1/b$, then the affine transformation t_a will map $s(P)$ to (1,1). Overall, the composite $t = t_a \circ s$ is an affine transformation which maps the given hyperbola to H, and maps P to (1, 1). We now state this as a corollary to Theorem 2.

Corollary Given any hyperbola and a point P on it, there is an affine transformation which maps the hyperbola onto the rectangular hyperbola $xy = 1$, and the point P to (1, 1).

Example 2 The tangent at the point P on a hyperbola meets the asymptotes at the points A and B. Prove that $PA = PB$.



Solution Let t be an affine transformation which maps the hyperbola onto the rectangular hyperbola $H = \{(x, y) : xy = 1\}$ in such a way that $t(P) = (1, 1)$. Then, by Theorem 6 of Subsection 2.5.1, the asymptotes of the hyperbola map to the asymptotes of H; and, by Theorem 7 of Subsection 2.5.1, the tangent at P maps to the tangent at (1,1).

By symmetry, (1, 1) is the midpoint of the line segment from $t(A)$ to $t(B)$. Since midpoints are preserved under the affine transformation t^{-1}, it follows that P is the midpoint of AB. □

Problem 3 P is a point on a hyperbola H with centre O. Prove that there exists a line ℓ through O such that all chords of the hyperbola which are parallel to ℓ are bisected by OP.

This result is an analogue for the hyperbola of the Conjugate Diameters Theorem for the ellipse (Theorem 3 of Subsection 2.2.3).

2.6 Exercises

Section 2.1

1. Let ABC be a triangle in which $AB = AC$. Prove that

$$ABC = \quad ACB.$$

Hint: Consider a reflection in the bisector of BAC.

2. Determine which of the following transformations $t : \mathbb{R}^2 \quad \mathbb{R}^2$ are Euclidean transformations.

(a) $t(\mathbf{x}) = \begin{matrix} \frac{1}{2} & \frac{\sqrt{3}}{2} \\ \frac{\sqrt{3}}{2} & \frac{1}{2} \end{matrix} \mathbf{x} + \begin{matrix} 3 \\ 1 \end{matrix}$

(b) $t(\mathbf{x}) = \begin{matrix} \frac{2}{3} & \frac{1}{3} \\ \frac{1}{3} & \frac{2}{3} \end{matrix} \mathbf{x} + \begin{matrix} 3 \\ 2 \end{matrix}$

(c) $t(\mathbf{x}) = \begin{matrix} \frac{1}{\sqrt{5}} & \frac{2}{\sqrt{5}} \\ \frac{2}{\sqrt{5}} & \frac{1}{\sqrt{5}} \end{matrix} \mathbf{x} + \begin{matrix} 2 \\ 3 \end{matrix}$

3. The Euclidean transformations t_1 and t_2 are given by

$$t_1(\mathbf{x}) = \begin{matrix} \frac{1}{\sqrt{5}} & \frac{2}{\sqrt{5}} \\ \frac{2}{\sqrt{5}} & \frac{1}{\sqrt{5}} \end{matrix} \mathbf{x} + \begin{matrix} 1 \\ 1 \end{matrix}$$

and

$$t_2(\mathbf{x}) = \begin{matrix} \frac{1}{\sqrt{5}} & \frac{2}{\sqrt{5}} \\ \frac{2}{\sqrt{5}} & \frac{1}{\sqrt{5}} \end{matrix} \mathbf{x} + \begin{matrix} 2 \\ 1 \end{matrix}.$$

Determine the composites $t_1 \quad t_2$ and $t_2 \quad t_1$.

4. Determine the inverse of each of the following Euclidean transformations.

(a) $t(\mathbf{x}) = \begin{matrix} \frac{5}{13} & \frac{12}{13} \\ \frac{12}{13} & \frac{5}{13} \end{matrix} \mathbf{x} + \begin{matrix} 4 \\ 5 \end{matrix}$

(b) $t(\mathbf{x}) = \begin{matrix} \frac{12}{13} & \frac{5}{13} \\ \frac{5}{13} & \frac{12}{13} \end{matrix} \mathbf{x} + \begin{matrix} 1 \\ 1 \end{matrix}$

5. The Euclidean transformations t_1 and t_2 are given by

$$t_1(\mathbf{x}) = \begin{matrix} \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \\ \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \end{matrix} \mathbf{x} + \begin{matrix} 1 \\ 1 \end{matrix}$$

and

$$t_2(\mathbf{x}) = \begin{matrix} \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \\ \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \end{matrix} \mathbf{x} + \begin{matrix} 1 \\ 1 \end{matrix}.$$

Determine the composite $t_2{}^{1} \quad t_1$.

Section 2.2

1. Determine whether or not each of the following transformations $t : \mathbb{R}^2$ $\mathbb{R}^2$ is an affine transformation.
   (a) $t(\mathbf{x}) = \begin{matrix} 2 & 2 \\ 3 & 3 \end{matrix} \mathbf{x} + \begin{matrix} 2 \\ 1 \end{matrix}$
   (b) $t(\mathbf{x}) = \begin{matrix} 5 & 2 \\ 2 & 5 \end{matrix} \mathbf{x} + \begin{matrix} 3 \\ 1 \end{matrix}$
   (c) $t(\mathbf{x}) = \begin{matrix} 1 & 1 \\ 1 & 2 \end{matrix} \mathbf{x}$
2. Write down an example (if one exists) of each type of transformation $t : \mathbb{R}^2 \quad \mathbb{R}^2$ described below. In each case, justify your answer.
   (a) An affine transformation t which is not a Euclidean transformation
   (b) A Euclidean transformation t which is not an affine transformation
   (c) A transformation t which is both Euclidean and affine
   (d) A transformation t which is one one, but is neither Euclidean nor affine
3. The affine transformations t_1 and t_2 are given by

$$t_1(\mathbf{x}) = \begin{matrix} 2 & 3 \\ 1 & 1 \end{matrix} \mathbf{x} + \begin{matrix} 1 \\ 1 \end{matrix}$$

   and

$$t_2(\mathbf{x}) = \begin{matrix} 1 & 2 \\ 1 & 1 \end{matrix} \mathbf{x} + \begin{matrix} 1 \\ 1 \end{matrix}.$$

   Determine the following composites.
   (a) $t_1 \quad t_2$ (b) $t_2 \quad t_1$ (c) $t_1 \quad t_1$
4. Determine the inverse of each of the following affine transformations.
   (a) $t(\mathbf{x}) = \begin{matrix} 2 & 3 \\ 3 & 5 \end{matrix} \mathbf{x} + \begin{matrix} 2 \\ 4 \end{matrix}$ (b) $t(\mathbf{x}) = \begin{matrix} 3 & 2 \\ 4 & 2 \end{matrix} \mathbf{x} + \begin{matrix} 1 \\ 2 \end{matrix}$
5. Prove that the transformation

$$t(\mathbf{x}) = 3\mathbf{x} \ (\mathbf{x} \quad \mathbb{R}^2)$$

   is an affine transformation, but not a parallel projection.
6. Which of the following are affine properties?
   (a) distance (b) collinearity (c) circularity
   (d) magnitude of angle (e) midpoint of line segment

Section 2.3

1. The affine transformation $t : \mathbb{R}^2 \quad \mathbb{R}^2$ is given by

$$t(\mathbf{x}) = \begin{matrix} 1 & 1 \\ 2 & 3 \end{matrix} \mathbf{x} + \begin{matrix} 2 \\ 4 \end{matrix}.$$

   Determine the image under t of each of the following lines.
   (a) $y = \quad 2x$ (b) $2y = 3x \quad 1$
2. The affine transformation $t : \mathbb{R}^2 \quad \mathbb{R}^2$ is given by

$$t(\mathbf{x}) = \begin{matrix} 4 & 5 \\ 1 & 1 \end{matrix} \mathbf{x} + \begin{matrix} 1 \\ 1 \end{matrix}.$$

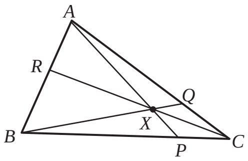
Determine the image under t of each of the following lines.
(a) $2x - 5y + 3 = 0$ (b) $3x + y - 4 = 0$

3. Determine the affine transformation which maps the points (0, 0), (1, 0) and (0, 1) to the points:
   (a) (0, −1), (1, 1) and (−1, 1), respectively;
   (b) (−4, −5), (1, 7) and (2, −9), respectively.
4. Determine the affine transformation which maps the points (1, 1), (3, 2) and (4, 1) to the points (0, 1), (1, 2) and (3, 7), respectively.
5. Determine the affine transformation which maps the points (1, −1), (5, −4) and (−2, 1) to the points (1, 1), (4, 0) and (0, 2), respectively.
6. Prove that the affine transformation t for which
$$t(\mathbf{x}) = \begin{pmatrix} -1 & 2 \\ 3 & -2 \end{pmatrix} \mathbf{x}$$
maps each point of the line $y = x$ in $\mathbb{R}^2$ onto itself.
7. Determine the matrices **A** and **b** for the affine transformation
$$t(\mathbf{x}) = \mathbf{A}\mathbf{x} + \mathbf{b},$$
where **A** and **b** are 2 × 2 and 2 × 1 matrices, respectively, given that t maps each point of the line $y = 0$ onto itself and (0,1) onto (2,3). Prove also that t is a parallel projection of $\mathbb{R}^2$ onto itself.

Section 2.4

1. The points P, Q, R and S lie on a line, in that order; the distances between them are 4 units, 2 units and 3 units, respectively. Determine the ratios *PR* : *RS* and *PS* : *SQ*.
2. A point X lies inside a triangle $\triangle ABC$, and the lines *AX*, *BX* and *CX* meet the opposite sides of the triangle at P, Q and R, respectively. The ratios *AR* : *AB* and *BP* : *BC* are 1 : 5 and 3 : 7, respectively. Determine the ratio *AC* : *AQ*.
3. Let be a line that crosses the sides *BC*, *CA* and *AB* of a triangle $\triangle ABC$ at three distinct points *P*, *Q* and *R*, respectively. The ratios *BC* : *CP* and *CQ* : *QA* are 3 : 2 and 1 : 3, respectively. Determine the ratio *AR* : *RB*.
4. *ABCD* is a parallelogram, and the point P divides *AB* in the ratio 2 : 1; the lines *AC* and *DP* meet at *Q*, and the lines *BQ* and *AD* meet at *R*.
   (a) Determine the images of P, Q and R under the affine transformation t which maps *A*, *D* and *C* to (0, 1), (0, 0) and (1, 0), respectively.
   (b) By considering the image of *ABCD* under t, determine the ratios *BQ* : *QR* and *AR* : *RD*.
5. The triangle $\triangle ABC$ has vertices $A(-1,2)$, $B(-3,-1)$ and $C(3,1)$, and the points $P\left(1,\frac{1}{3}\right)$, $Q\left(1,\frac{3}{2}\right)$ and $R\left(-\frac{5}{3},1\right)$ lie on *BC*, *CA* and *AB*, respectively.
   (a) Determine the ratios in which P, Q and R divide the sides of the triangle.
   (b) Determine whether or not the lines *AP*, *BQ* and *CR* are concurrent.

6. The triangle ABC has vertices $A(2,0)$, $B(\;3,0)$ and $C(3,\;3)$, and the points $P(\;1,\;1)$, $Q(1,3)$ and $R\;\frac{1}{4},0$ lie on BC, CA and AB, respectively.
   (a) Determine the ratios in which P, Q and R divide the sides of the triangle.
   (b) Determine whether or not the points P, Q and R are collinear.
7. ABC is a triangle, and X a point which does not lie on any of its (extended) sides. Also, AX meets BC at P, BX meets CA at Q and CX meets BA at R. Prove that
$$\frac{AX}{XP} = \frac{AR}{RB} + \frac{AQ}{QC}.$$
   (This result is often known as van Aubel s Theorem.)



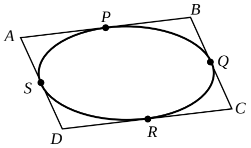
8. ABC is a triangle, and X a point which does not lie on any of its (extended) sides. Next, AX meets BC at P, BX meets CA at Q and CX meets BA at R. Also, RQ meets BC at L, PR meets CA at M and PQ meets BA at N. Prove that L, M and N are collinear.
   Hint: Apply the result of Problem 5 in Subsection 2.4.3 to ABC and points L, M and N in turn. Then evaluate the product $\frac{BL}{LC} \bullet \frac{CM}{MA} \bullet \frac{AN}{NB}$.

Direct calculation using coordinates is also possible, but very tedious!

9. Three disjoint circles of unequal radii lie in the plane, their centres being non-collinear. Pairs of tangents are drawn to each pair of circles such that the point of intersection of the two tangents to each pair of circles lies beyond the two circles. Prove that the three intersection points are collinear.

Section 2.5

1. An ellipse touches the sides AB, BC, CD, DA of a parallelogram $ABCD$ at the points P, Q, R, S, respectively. Prove that the lengths CQ, QB, BP and CR satisfy the equation
$$\frac{CQ}{QB} = \frac{CR}{BP}.$$



2. Determine the equation of the image of the parabola P with equation $y = x^2$ under the affine transformation $t : \mathbb{R}^2 \quad \mathbb{R}^2$ given by
$$t(\mathbf{x}) = \begin{matrix} 1 & 0 \\ 2 & 1 \end{matrix} \mathbf{x}.$$
   Show that the image of the vertex of P is not the vertex of $t(P)$.

This proves that the property of being a vertex of a parabola is not an affine property.

3. Prove that for any triangle ABC there exists an ellipse that touches the sides AB, BC and CA at their midpoints.
4. Let $P(a\cos\;, b\sin\;)$, where is not a multiple of $/2$, be a point on the ellipse $C : \frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$, where $a \quad b > 0$; and $P\,(a\cos\;, a\sin\;)$ the corresponding point on the auxiliary circle $C : x^2 + y^2 = a^2$. Prove that the tangents at P to C and at P to C meet on the x-axis.
   Hint: Write down an affine transformation that maps C to C and P to P, and that maps each point of the x-axis to itself.
5. Given any two points P and P on ellipses E and E, respectively, show that there exists an affine transformation that maps E to E and P to P.

This result is analogous to that for hyperbolas in the Corollary in Subsection 2.5.2.

6. Find the endpoints of the chord AB of the hyperbola H with equation $xy = 1$ that is bisected by the point $P(2,1)$.

7. E is the ellipse with equation $\frac{x^2}{9} + \frac{y^2}{4} = 1$, and $P \quad \frac{3}{5}, \frac{2}{5}$ is a point inside E. AB is a chord of E through P, and O is the centre of E. Find the maximum value of $\frac{AP}{PB}$ as A varies on E.

Summary of Chapter 2

Section 2.1: Geometry and transformations

1. An **isometry** of $\mathbb{R}^2$ is a function which maps $\mathbb{R}^2$ onto $\mathbb{R}^2$ and preserves distances.
   Every isometry of $\mathbb{R}^2$ has one of the following forms:
   a translation along a line in $\mathbb{R}^2$;
   a reflection in a line in $\mathbb{R}^2$;
   a rotation about a point in $\mathbb{R}^2$;
   a composite of translations, reflections and rotations in $\mathbb{R}^2$.
   The set of all isometries of $\mathbb{R}^2$ forms a group under composition of functions; in particular, the composite of two isometries is an isometry.
2. **Euclidean geometry** is the study of those properties of figures that are unchanged by the group of isometries.
   These properties are called **Euclidean properties**, and include distance, angle, collinearity of points and concurrence of lines.
3. The **Kleinian view of geometry** is the idea that geometry can be thought of in terms of a group of transformations acting on a space.
4. The transformations of $\mathbb{R}^2$ given by

$$\begin{array}{c} x \\ y \end{array} \quad \begin{array}{cc} \cos & \sin \\ \sin & \cos \end{array} \quad \begin{array}{c} x \\ y \end{array} + \begin{array}{c} e \\ f \end{array}, \text{ and}$$

$$\begin{array}{c} x \\ y \end{array} \quad \begin{array}{cc} \cos & \sin \\ \sin & \cos \end{array} \quad \begin{array}{c} x \\ y \end{array} + \begin{array}{c} e \\ f \end{array}$$

   are isometries; they represent, respectively, anticlockwise rotation about the origin through an angle followed by a translation by (e, f), and reflection in a line through the origin that makes an angle $/2$ with the x-axis followed by a translation by (e, f).
   Every isometry of $\mathbb{R}^2$ is of one or other of these two forms
5. A **Euclidean transformation** of $\mathbb{R}^2$ is a function $t : \mathbb{R}^2 \quad \mathbb{R}^2$ of the form $t(\mathbf{x}) = \mathbf{Ux} + \mathbf{a}$, where $\mathbf{U}$ is an orthogonal 2×2 matrix and $\mathbf{a} \quad \mathbb{R}^2$. The set of all Euclidean transformations of $\mathbb{R}^2$ is denoted by $E(2)$.
6. Every isometry of $\mathbb{R}^2$ is a Euclidean transformation of $\mathbb{R}^2$, and vice versa.
7. The set of Euclidean transformations of $\mathbb{R}^2$ forms a group under the operation of composition of functions.
8. The inverse of the Euclidean transformation $t(\mathbf{x}) = \mathbf{Ux} + \mathbf{a}$ is given by $t^{\ 1}(\mathbf{x}) = \mathbf{U}^{\ 1}\mathbf{x} \quad \mathbf{U}^{\ 1}\mathbf{a}$.

9. **Euclidean geometry** is the study of those properties of figures that are preserved by Euclidean transformations of $\mathbb{R}^2$.
10. A figure F_1 is **Euclidean-congruent** to a figure F_2 if there is a Euclidean transformation which maps F_1 onto F_2. Loosely speaking, two figures are congruent if they have the same size and shape.

    Euclidean congruence is an equivalence relation.

    A figure F_1 is ***G*-congruent** to a figure F_2 in some geometry defined by a group G of transformations acting on the space of the geometry if there is a transformation in G which maps F_1 onto F_2. G-congruence is an equivalence relation.

Section 2.2: Affine Transformations and Parallel Projections

1. An **affine transformation** of $\mathbb{R}^2$ is a function $t : \mathbb{R}^2 \to \mathbb{R}^2$ of the form $t(\mathbf{x}) = \mathbf{Ax} + \mathbf{b}$, where $\mathbf{A}$ is an invertible 2×2 matrix and $\mathbf{b} \in \mathbb{R}^2$. The set of all affine transformations of $\mathbb{R}^2$ is denoted by $A(2)$.

    Every Euclidean transformation of $\mathbb{R}^2$ is an affine transformation.
2. The set of affine transformations $A(2)$ forms a group under the operation of composition of functions.

    The inverse of the affine transformation $t(\mathbf{x}) = \mathbf{Ax} + \mathbf{b}$ is $t^{-1}(\mathbf{x}) = \mathbf{A}^{-1}\mathbf{x} - \mathbf{A}^{-1}\mathbf{b}$.
3. **Affine geometry** is the study of those properties (called **affine properties**) of figures in the plane $\mathbb{R}^2$ that are preserved by affine transformations.

    Basic properties of affine transformations

    Affine transformations:

    1. map straight lines to straight lines;
    2. map parallel straight lines to parallel straight lines;
    3. preserve ratios of lengths along a given straight line.
4. A **parallel projection** is a one-one mapping of $\mathbb{R}^2$ to itself defined in the following way. Let π_1 and π_2 be planes in $\mathbb{R}^3$, with parallel rays of light shining through them; then the function p which maps each point P in π_1 to the corresponding point P' in π_2 is a parallel projection from π_1 onto π_2.

    If π_1 and π_2 are parallel, then the parallel projection from π_1 onto π_2 is an isometry.
5. **Basic properties of parallel projections**

    Parallel projections:

    1. map straight lines to straight lines;
    2. map parallel straight lines to parallel straight lines;
    3. preserve ratios of lengths along a given straight line.
6. A **diameter** of an ellipse is a chord of the ellipse that passes through its centre.

    Midpoint Theorem Let ℓ be a chord of an ellipse. Then the midpoints of the chords parallel to ℓ lie on a diameter of the ellipse.
7. **Conjugate Diameters Theorem** Let ℓ be a diameter of an ellipse. Then there is another diameter m of the ellipse such that

(a) the midpoints of all chords parallel to ℓ lie on m;
(b) the midpoints of all chords parallel to m lie on ℓ.

The directions of these two diameters are called **conjugate directions**, and the diameters are called **conjugate diameters**.

8. Given any ellipse, there is a parallel projection which maps the ellipse onto a circle.
9. Under parallel projection certain properties of figures, such as length and angle, are not necessarily preserved. This is one difference between Euclidean geometry and affine geometry.
10. Each parallel projection is an affine transformation.

    However, an affine transformation is not necessarily a parallel projection. For example, the **doubling map** of $\mathbb{R}^2$ to itself given by $t(\mathbf{v}) = 2\mathbf{v}$ is an affine transformation but cannot be modelled by a parallel projection.
11. An affine transformation t is **completely determined** by its effect on the three non-collinear points (0,0), (1,0) and (0,1).

    Hence if we know the points onto which (0,0), (1,0) and (0,1) are mapped by t, we can determine $\mathbf{A}$ and $\mathbf{b}$ in the formula $t(\mathbf{x}) = \mathbf{Ax} + \mathbf{b}$, $\mathbf{x} \in \mathbb{R}^2$.
12. An affine transformation can be expressed as the composite of two parallel projections.

Section 2.3: Properties of Affine Transformations

1. **Strategy** To determine the image of a line or conic in $\mathbb{R}^2$ under an affine transformation $t : \mathbb{R}^2 \to \mathbb{R}^2$ given by $t(\mathbf{x}) = \mathbf{Ax} + \mathbf{b}$, let $\mathbf{x}$ and coordinates (x, y) denote points in the domain copy of $\mathbb{R}^2$, and $\mathbf{x}'$ and coordinates (x', y') denote points in the codomain copy. Then:
    1. express the relationship between $\mathbf{x}$ and $\mathbf{x}'$ in the form $\mathbf{x} = \mathbf{A}^{-1}\mathbf{x}' - \mathbf{A}^{-1}\mathbf{b}$;
    2. determine formulas for x and y in terms of x' and y';
    3. substitute for x and y in the equation of the line or conic;
    4. drop the dashes from x' and y'.

    The resulting equation describes the image under t.
2. **Strategy** To determine the unique affine transformation $t(\mathbf{x}) = \mathbf{Ax} + \mathbf{b}$ which maps (0,0), (1,0) and (0,1) to the three non-collinear points $\mathbf{p}$, $\mathbf{q}$ and $\mathbf{r}$, respectively:
    1. take $\mathbf{b} = \mathbf{p}$;
    2. take $\mathbf{A}$ to be the matrix with columns given by $\mathbf{q} - \mathbf{p}$ and $\mathbf{r} - \mathbf{p}$.

    Warning This Strategy requires that $\mathbf{p}$, $\mathbf{q}$ and $\mathbf{r}$ are non-collinear. If they are collinear, the matrix $\mathbf{A}$ described in the Strategy is non-invertible, and hence the transformation given by the procedure in the Strategy is not an affine transformation.
3. **Fundamental Theorem of Affine Geometry** Let $\mathbf{p}, \mathbf{q}, \mathbf{r}$ and $\mathbf{p}', \mathbf{q}', \mathbf{r}'$ be two sets of three non-collinear points in $\mathbb{R}^2$. Then:
    (a) there is an affine transformation t which maps $\mathbf{p}, \mathbf{q}$ and $\mathbf{r}$ to $\mathbf{p}', \mathbf{q}'$ and $\mathbf{r}'$, respectively;
    (b) the affine transformation t is unique.

Strategy To determine the affine transformation t which maps three non-collinear points **p, q** and **r** to another three non-collinear points **p** , **q** and **r** , respectively:

1. determine the affine transformation t_1 which maps (0,0), (1,0) and (0,1) to the points **p, q** and **r**, respectively;
2. determine the affine transformation t_2 which maps (0,0), (1,0) and (0,1) to the points **p** , **q** and **r** , respectively;
3. calculate the composite $t = t_2 \quad t_1^{\ 1}$.

4. Two figures are **affine-congruent** if there is an affine transformation which maps one onto the other.

   All triangles are affine-congruent.

5. An affine transformation preserves ratios of lengths along parallel straight lines.

Section 2.4: Using the Fundamental Theorem of Affine Geometry

1. **Median Theorem** The medians of any triangle are concurrent.
2. If a point R divides a line segment PQ in the **ratio** $(1 \quad) : \quad$, then $\frac{PR}{RQ} = \frac{1}{\quad}$. The **magnitude** of the ratio equals the length of PR divided by the length of RQ, and the ratio is **positive** if $0 < \quad < 1$ (when PR and RQ lie in the same direction) and **negative** if $\quad < 0$ or $\quad > 1$ (when PR and RQ lie in opposite directions).

   If P, Q and R have coordinates (x_P, y_P), (x_Q, y_Q) and (x_R, y_R), respectively, then $\frac{PR}{RQ} = \frac{x_R \quad x_P}{x_Q \quad x_R}$ and $\frac{PR}{RQ} = \frac{y_R \quad y_P}{y_Q \quad y_R}$. (If the denominator of one of these fractions vanishes, then use the other to determine the ratio.)
3. **Ceva's Theorem** Let ABC be a triangle, and let X be a point which does not lie on any of its (extended) sides. If AX meets BC at P, BX meets CA at Q and CX meets BA at R, then

$$\frac{AR}{RB} \cdot \frac{BP}{PC} \cdot \frac{CQ}{QA} = 1.$$

4. **Converse to Ceva's Theorem** Let P, Q and R be points other than vertices on the (possibly extended) sides BC, CA and AB of a triangle ABC, such that $\frac{AR}{RB} \cdot \frac{BP}{PC} \cdot \frac{CQ}{QA} = 1$. Then the lines AP, BQ and CR are concurrent.
5. **Menelaus's Theorem** Let ABC be a triangle, and let be a line that crosses the sides BC, CA and AB at three distinct points P, Q and R, respectively. Then $\frac{AR}{RB} \cdot \frac{BP}{PC} \cdot \frac{CQ}{QA} = \quad 1$.
6. **Converse to Menelaus' Theorem** Let P, Q and R be points other than vertices on the (possibly extended) sides BC, CA and AB of a triangle ABC, such that $\frac{AR}{RB} \cdot \frac{BP}{PC} \cdot \frac{CQ}{QA} = \quad 1$. Then the points P, Q and R are collinear.

7. Many results about properties of triangles (such as collinearity, lines being parallel, and ratios of lengths along a given line) are preserved under affine transformations, are proved following a standard pattern.

   First, we choose a particular type of triangle for which it is easy to prove the result. Then, by asserting the existence of an affine transformation from that triangle to an arbitrary triangle, we may deduce that the result holds for all triangles.
8. Let $A = (a_1, a_2)$, $B = (b_1, b_2)$ and $C = (c_1, c_2)$ be three non-collinear points in the plane $\mathbb{R}^2$; we call ABC the **triangle of reference**. Then a point (x, y) in the plane has **barycentric coordinates** $(\; , \; , \;)$ with respect to ABC if

$$x = \; a_1 + \; b_1 + \; c_1,$$
$$y = \; a_2 + \; b_2 + \; c_2, \text{ and}$$
$$1 = \; + \; + \; .$$

   If we set $\mathbf{M} = \begin{pmatrix} a_1 & b_1 & c_1 \\ a_2 & b_2 & c_2 \\ 1 & 1 & 1 \end{pmatrix}$, then $\mathbf{M}$ is invertible. Also $\begin{pmatrix} x \\ y \\ 1 \end{pmatrix} = \mathbf{M}$ and $= \mathbf{M}^{1} \begin{pmatrix} x \\ y \\ 1 \end{pmatrix}$.
9. The points P, Q and R with barycentric coodinates $({}_1, {}_1, {}_1)$, $({}_2, {}_2, {}_2)$ and $({}_3, {}_3, {}_3)$ are collinear if and only if $\begin{vmatrix} {}_1 & {}_2 & {}_3 \\ {}_1 & {}_2 & {}_3 \\ {}_1 & {}_2 & {}_3 \end{vmatrix} = 0$.

   The line through the points with barycentric coordinates $({}_1, {}_1, {}_1)$ and $({}_2, {}_2, {}_2)$ has equation $\begin{vmatrix} {}_1 & {}_2 & \\ {}_1 & {}_2 & \\ {}_1 & {}_2 & \end{vmatrix} = 0$.
10. **Section Formula** The point R that divides the line joining the points P and Q with barycentric coordinates $({}_1, {}_1, {}_1)$ and $({}_2, {}_2, {}_2)$ in the ratio $(1 \quad) : \;$ has barycentric coordinates

$$(\; , \; , \;) = \; ({}_1, {}_1, {}_1) + (1 \quad)({}_2, {}_2, {}_2).$$

Section 2.5: Affine Transformations and Conics

1. Every ellipse is affine-congruent to the unit circle with equation $x^2 + y^2 = 1$.

   Every hyperbola is affine-congruent to the rectangular hyperbola with equation $xy = 1$.

   Every parabola is affine-congruent to the parabola with equation $y^2 = x$.
2. Affine transformations map ellipses to ellipses, parabolas to parabolas, and hyperbolas to hyperbolas.

   In Affine Geometry:

   (a) all ellipses are congruent to each other;

(b) all hyperbolas are congruent to each other;
(c) all parabolas are congruent to each other.

Non-degenerate conics are congruent only to non-degenerate conics of the same type.

3. Let t be an affine transformation, and let C be an ellipse or hyperbola with centre R. Then $t(C)$ has centre $t(R)$.
4. Let t be an affine transformation, and let H be a hyperbola with asymptotes $_1$ and $_2$. Then $t(H)$ has asymptotes $t(\ _1)$ and $t(\ _2)$.
5. Let t be an affine transformation, and let be a tangent to a conic C. Then $t(\ )$ is a tangent to the conic $t(C)$.
6. Affine geometry can be used to tackle problems involving conics when the property being investigated is an affine property. We first use an affine transformation to map the original conic onto one of our standard conics, tackle the problem in hand there, and then map back to the original conic.
7. Given any hyperbola and a point P on it, there is an affine transformation which maps the hyperbola onto the rectangular hyperbola $xy = 1$, and the point P to (1,1).

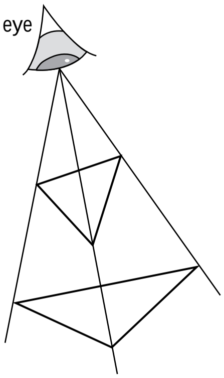
3 Projective Geometry: Lines

Geometry is one branch of mathematics that has an obvious relevance to the 'real world'. Earlier, we studied some results in Euclidean geometry and we described the group of Euclidean transformations, the isometries. We saw that the Euclidean transformations preserve distances and angles, and have a definite physical significance.

Chapters 1 and 2.

In this chapter we study *projective geometry*, a very different type of geometry, that has important but less obvious applications. It was discovered through artists' attempts over many centuries to paint realistic-looking pictures of scenes composed of objects situated at differing distances from the eye. How can three-dimensional scenes be represented on a two-dimensional canvas? Projective geometry explains how an eye perceives 'the real world', and so explains how artists can achieve realism in their work.

For example, in Computer Graphics and in Art.



In Section 3.1, we look at the development of perspective in Art and explain the concept of a *perspectivity*. We describe Desargues' Theorem, which concerns a curious property of two triangles whose vertices are in perspective from a single point, and so explain that perspective can play a key role in the statement and the proof of theorems in mathematics.

In Section 3.2, we define the term *projective point* (or *Point*) and call the set of all such Points the *projective plane*, which we denote by RP^2. We also define a *projective line* (or *Line*). To enable us to tackle problems in projective geometry algebraically, we introduce *homogeneous coordinates* to specify the Points in RP^2.

In Section 3.3, we define the projective transformations of RP^2 and use them to define projective geometry. We also prove the *Fundamental Theorem of Projective Geometry*, which states that given two sets of four Points there is a unique projective transformation of RP^2 that maps the Points in one set to the corresponding Points in the other set. This crucial result enables us to apply a preliminary transformation to many geometric problems, thereby simplifying their solution by reducing the arithmetic involved. It turns out that there is a close connection between the idea of perspective in R^3 and projective transformations.

We also require that no three Points in either set lie on a Line.

In Section 3.4, we use the Fundamental Theorem of Projective Geometry to prove several results, including Desargues' Theorem. We also introduce the concept of *duality*, which involves a remarkable relationship between Points and Lines.

Finally, in Section 3.5, we note that the ideas of distance and ratio of distances along a line have no immediate analogues in RP^2; nevertheless, we are able to define a related quantity called the *cross-ratio* of four collinear Points in RP^2. This quantity is very useful in proving various mathematical results, and it has real life applications such as in aerial photography.

3.1 Perspective

3.1.1 Perspective in Art

The first pictures were probably Cave Art wall paintings: for example, depictions of animals and hunters. Up to the Middle Ages, most pictures were drawn on walls, floors or ceilings of buildings and were intended to convey messages rather than to be accurate illustrations of what an eye might see. For example, Christian religious art portrayed Christ and the Saints, the Bayeux tapestry outlined events such as the Norman Conquest and the Battle of Hastings, and so on.

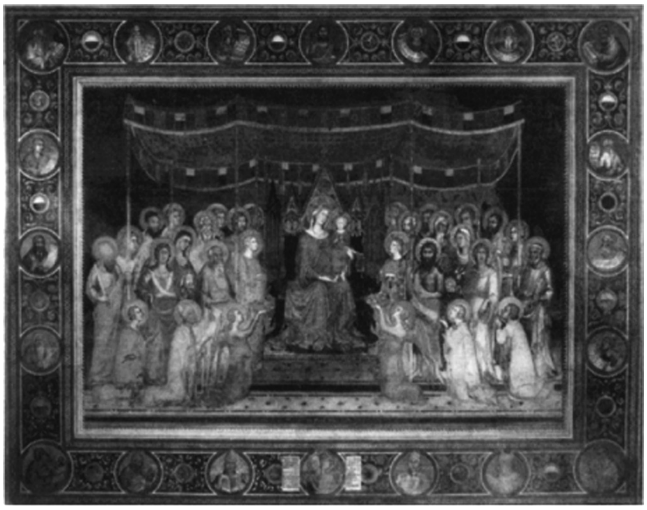
These prints are reproduced by kind permission of A.A. & A. Ancient Art and Architecture Collection.

To the modern eye, the people and animals in these pictures appear to be rather stylized, and the whole scene seems very two-dimensional. The events illustrated do not appear to be properly integrated into the background, even if this is included.

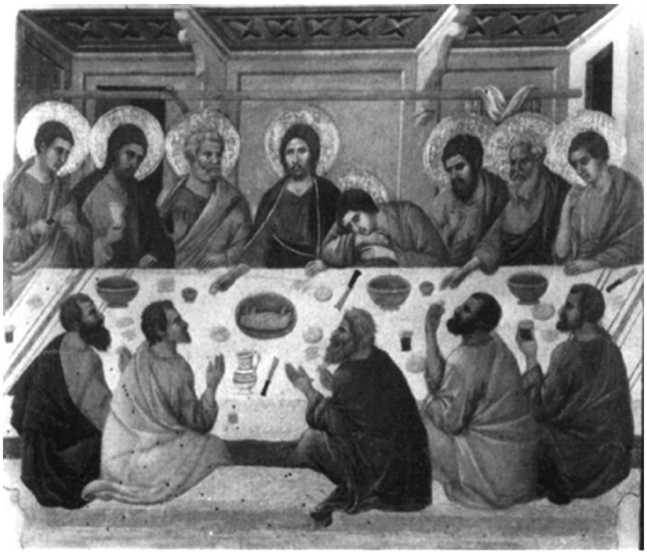
Towards the end of the 13th century, early Renaissance artists began to attempt to portray real situations in a realistic way. For example, people at the back of a group would be drawn higher up than those at the front a technique known as *terraced perspective.*



Simone Martini Maestà Palazzo Pubblico, Sala del Mappamodo, Siena (su concessione del commune di Siena). Foto LENSINI Siena.

As artists struggled to find better techniques to improve the realism of their work, the idea of *vertical perspective* was developed by the Italian school of artists (including Duccio (1255–1318) and Giotto (1266–1337)). To create an impression of depth in a scene, the artist would represent pairs of parallel lines that are symmetrically placed either side of the scene by lines that meet on the centre line of the picture. The method is not totally realistic, since objects do not appear to recede into the distance in the way that might be expected. The problem of depicting 'distant objects looking smaller', with a properly integrated foreground and background, was tackled by many artists, including notably Ambrogio Lorenzetti (c. 1290–1348).

Giotto is sometimes called the 'Father of Modern Painting'.

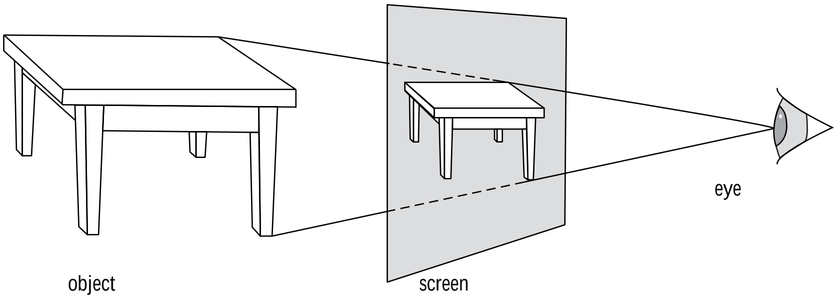


'Last Supper' painted by Duccio; Opera del Duomo, Siena. Foto LENSINI Siena.

The modern system of *focused perspective* was discovered around 1425 by the sculptor and architect Brunelleschi (1377–1446), developed by the painter and architect Leone Battista Alberti (1404 1472), and finally perfected by Leonardo da Vinci (1452 1519).

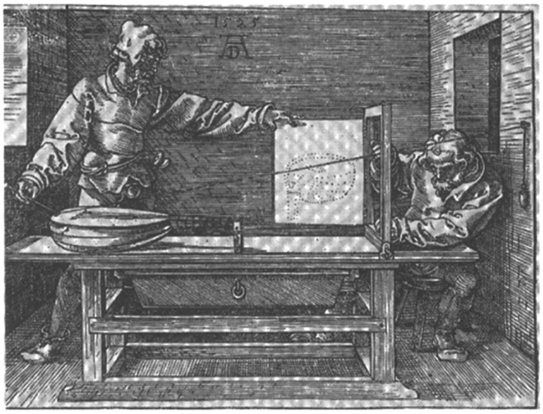
Alberti wrote that the first necessity for a painter is to know geometry .

These artists realized that what the eye actually sees of a scene are the various rays of light travelling from each point in the scene to the eye. An effective way of deciding how to depict a three-dimensional scene on a two-dimensional canvas so as to create a realistic impression is therefore as follows. Imagine a glass screen placed between the eye and the three-dimensional scene. Each line joining the eye to a point of the scene pierces the glass screen at some point. The set of all such points forms an image on the screen known as a *cross-section*. Since the eye cannot distinguish between light rays coming from the points of the actual scene and light rays coming from the corresponding points of the cross-section (since these are in exactly the same direction), the cross-section produces the same impression as the original scene. In other words, the cross-section gives a realistic two-dimensional representation of the three-dimensional scene.



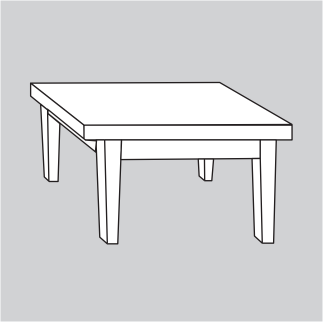
The German artist Albrecht Dürer (1471 1528) introduced the term *perspective* (from the Latin verb meaning to see through) to describe this technique, and illustrated it by a series of well-known woodcuts in his book *Underweysung der Messung mit dem Zyrkel und Rychtsscheyed* (1525). The Dürer woodcut below shows an artist peering through a grid on a glass screen to study perspective and the effect of foreshortening.

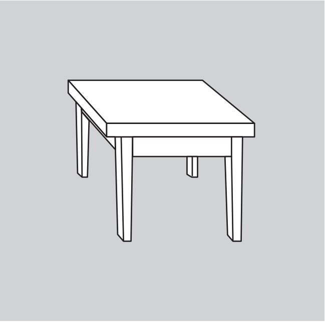
In English: *Instruction on measuring with compass and straight edge.*
We discuss foreshortening in Subsection 3.1.2.



By permission of The British Library. c The British Library Board C.119.h.7(l).

Of course, the picture displayed on the screen is just one representation of the scene. If the screen is placed closer to, or further away from, the eye, the size of the cross-section changes. Also, the screen may be placed at a different angle for a given position of the eye, or the eye itself may be moved to a different position. In each case, a different cross-section is obtained, though they are all related to each other.



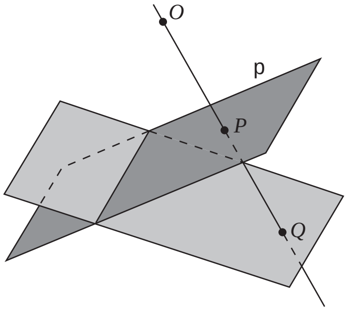


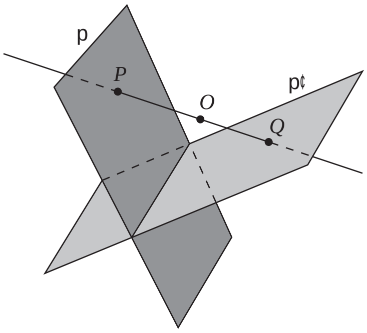
3.1.2 Mathematical Perspective

To help us understand the relationship between different representations of a scene, we now look at perspective from a mathematical point of view. In place of an eye and light rays travelling to it, we use the family of all lines in $\mathbb{R}^3$ through a given point. For convenience, this point will often be the origin O. The glass screen is replaced by a plane in $\mathbb{R}^3$ that does not pass through the origin.

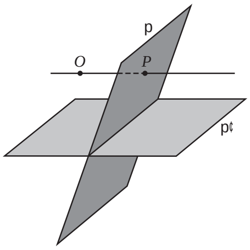
In order to compare the cross-sections that appear on different screens, we consider two planes and that do not pass through O. A point P in and a point Q in are said to be *in perspective from O* if there is a straight line through O, P and Q. A *perspectivity from to* centred at O is a function that maps a point P of to a point Q of whenever P and Q are in perspective from O. Notice that the planes and may lie on the same side of O as shown on the left below, or they may lie on opposite sides of O as shown on the right.

In terms of O representing an eye, the figure on the right corresponds to the observer having the ability to look simultaneously both forwards and backwards!

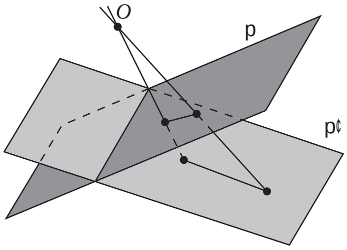


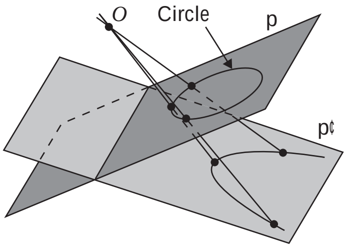


One complication with the above definition of a perspectivity is that the domain of the perspectivity is not necessarily the whole of . Indeed, if *P* is any point of such that *OP* is parallel to , as shown in the margin, then *P* cannot have an image in , and cannot therefore belong to the domain of the perspectivity. From a mathematical point of view, this need to exclude such exceptional points from the domain of a perspectivity turns out to be rather a nuisance. In Subsection 3.2.3 we shall therefore reformulate the definition of a perspectivity in such a way that these exceptional points can be included in the domain.



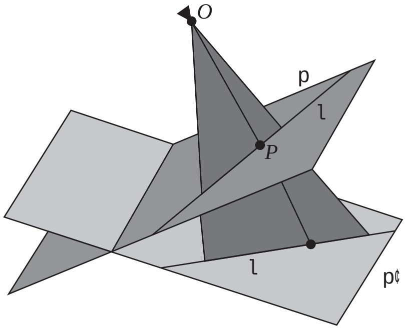
Even with only the preliminary definition of perspectivity given above, it is clear that some features of figures are preserved under a perspectivity, while others are not. For example, the figure on the left below illustrates a particular perspectivity in which a line segment in one plane maps onto a line segment in another plane. This suggests that collinearity is preserved by a perspectivity. On the other hand, the figure on the right illustrates a perspectivity in which a circle in one plane appears to map to a parabolic shape in another plane, which suggests that circularity is not preserved.



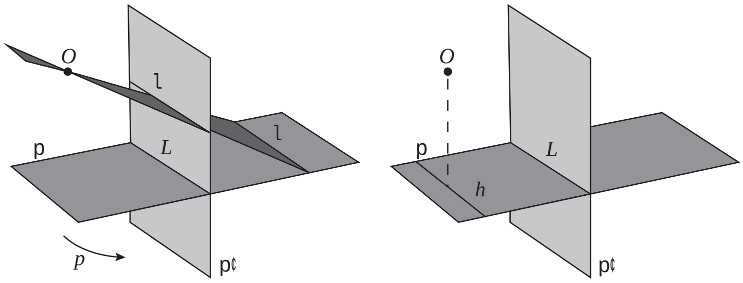


One of our main tasks is to study the images of standard configurations such as lines and conics under perspectivities. This chapter deals with lines; the next chapter deals with conics.

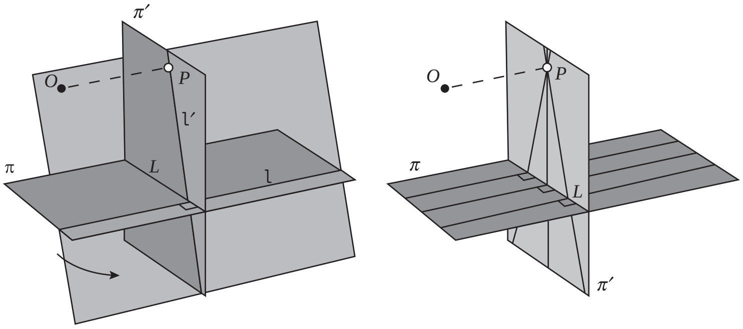
Consider a perspectivity with centre *O* that maps points in a plane to points in a plane . A convenient way to visualize the image of a line under the perspectivity is to consider an arbitrary point *P* on . As *P* moves along , the line *OP* sweeps out a plane. The line where this plane intersects is the image of .



To be specific, consider the perspectivity p with centre O that maps points in a horizontal plane to points in a vertical plane , and let L be the line where and intersect. Under p, every line in that is parallel to L maps to a horizontal line in . In particular, L maps to itself. The only exception is the line h that passes through the foot of the perpendicular from O to . This line does not have an image in since the lines joining points of h to O are parallel to .



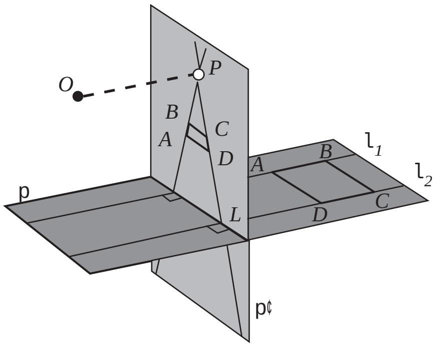
Next, consider the image under the same perspectivity p of a line in that is perpendicular to L. To do this, let P denote the foot of the perpendicular from O to the plane . Although P is not the image of any point of , the plane through O and meets in some line that passes through P. It follows that the image of under p is some line through P, with the point P itself omitted.



The above argument works for *any* line in that is perpendicular to L. All such lines are mapped by the perspectivity p to lines in that pass through P, and that omit the point P itself.

We may combine our observations concerning lines in that are parallel to L or perpendicular to L in the following way. Let $ABCD$ be a rectangle in on the opposite side of L from O, with sides AB and CD that lie on lines $_1$ and $_2$, perpendicular to L. Then AD and BC both map onto horizontal lines in between L and P. As the side BC recedes from L, its image $B\ C$ under the perspectivity p moves further up towards P, becoming shorter as it moves.

Artists describe this shortening of the image on of lines of equal length in as *foreshortening*.

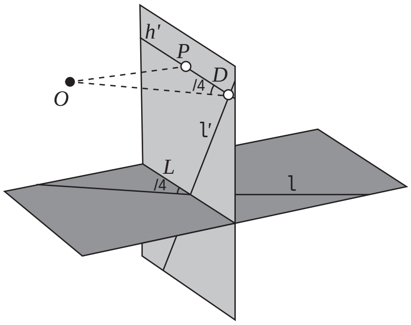


To an observer whose eye is located at O, the lines $_1$ and $_2$ *appear* to meet at infinity, and this corresponds to their images under p *appearing* to meet at P. The point P is called the *principal vanishing point* of the perspectivity p because the images in of all lines in perpendicular to L appear to vanish there.

You can think of $_1$ and $_2$ as a pair of railroad lines disappearing into the distance.

In fact, a perspectivity has many vanishing points. For instance, let be any line in that intersects L at an angle of /4. Now let h be the horizontal line in through P, and let D be the point on h such that OD is parallel to . Then the plane through O and meets in some line that passes through D. It follows that the image of under p is a line through D, with the point D itself omitted.

Here the symbol is being used in two different ways: as a label for the embedding plane, and as an angle.



The point D is called a *diagonal vanishing point* of the perspectivity. All lines in the plane that are parallel to the given line have images in that are lines through D, with the point D itself omitted.

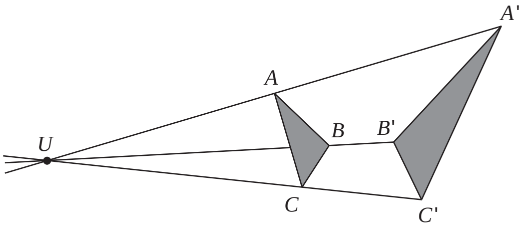
That is, the images appear to *vanish* at D.

In the same way, each point of the horizontal line h in through P is a *vanishing point* for the images of all lines in in some direction; hence the line h

is called the *vanishing line*. It corresponds to the horizon in the plane in other words, to the points at infinity towards which an observer s eye is pointing when looking in a horizontal direction.

3.1.3 Desargues Theorem

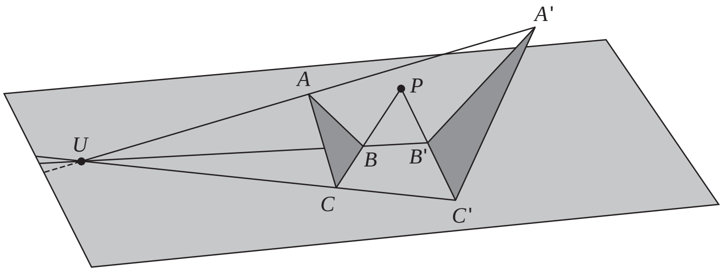
The idea that information in three dimensions can be related to information in two dimensions, and vice versa, plays an important role in mathematics just as it does in Art. For example, consider the following three-dimensional figure that consists of two triangles ABC and $A B C$ which are in perspective from a point U. For the moment we shall assume that no pair of corresponding sides BC and $B C$, CA and $C A$, and AB and $A B$, are parallel.



We shall show that this three-dimensional figure has the property that BC and $B C$, CA and $C A$, AB and $A B$ meet at P, Q, R, respectively, where P, Q and R are collinear. This will enable us to formulate an equivalent two-dimensional result, known as *Desargues Theorem.*

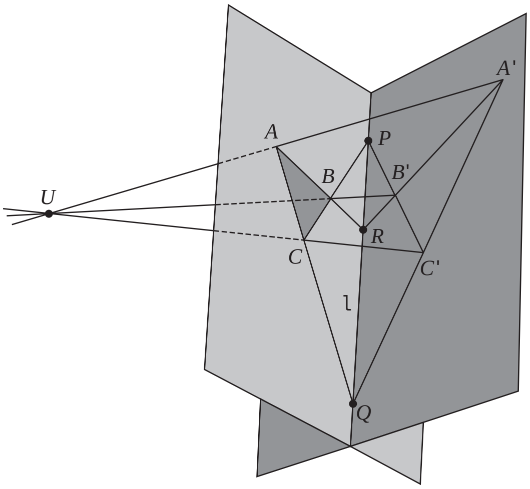
Girard Desargues (1593 1662) was a French engineer and architect.

To prove the three-dimensional result, observe that both BC and $B C$ lie in the plane that passes through the points U, B and C. Since BC and $B C$ are coplanar but not parallel, they must meet at some point P.



Similarly, the sides CA and $C A$ meet at some point Q, and the sides AB and $A B$ meet at some point R.

Since the points P, Q and R lie both on the plane which contains the triangle ABC and on the plane which contains the triangle $A B C$, they must lie on the line where the two planes meet. It follows that P, Q and R are collinear.



To obtain the equivalent two-dimensional result, imagine that you are viewing the three-dimensional configuration through a transparent screen. Since this viewing process will not alter the collinearity of points or the coincidence of lines, we may reinterpret the three-dimensional result in terms of the image on the screen to obtain the following theorem.

We give a rigorous proof of Desargues Theorem in Theorem 1, Subsection 3.4.1.

Theorem 1 Desargues' Theorem
Let ABC and $A B C$ be triangles in $\mathbb{R}^2$ such that the lines AA, BB and CC meet at a point U. Let BC and $B C$ meet at P, CA and $C A$ meet at Q, and AB and $A B$ meet at R. Then P, Q and R are collinear.

Strictly speaking, we have not proved this theorem since it is not immediately obvious that ABC and $A B C$ can be obtained as images of triangles in $\mathbb{R}^3$ which have corresponding sides that are not parallel. Nevertheless, the above argument does provide reasonably convincing evidence that the theorem is true.

One remarkable feature of the above argument is the way in which the geometry of the figure on the transparent screen is characterized by the rays of light that enter an eye. Thus a point on the screen corresponds to a single ray of light that enters the eye, a line on the screen corresponds to a plane of rays of light that enter the eye, and so on. The geometry of the figure can be investigated entirely in terms of these rays of light. The screen is needed only to interpret the result in terms of a two-dimensional figure.

In the rest of Chapters 3 and 4, we introduce a geometry known as *projective geometry* that enables us to work with figures on a plane (a screen) as if they correspond to rays of light that enter an eye in the way described above.

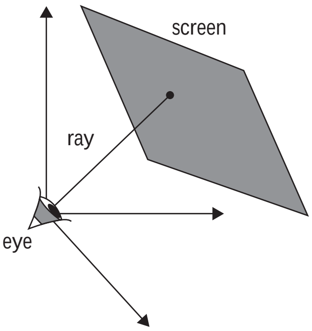
3.2 The Projective Plane $\mathbb{RP}^2$

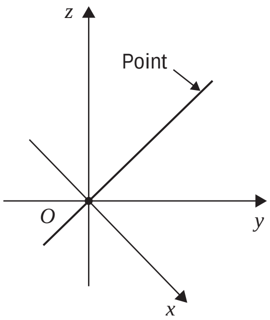
You have already met the Kleinian view that a geometry consists of a group of transformations acting on a space of points. In this section we begin our discussion of projective geometry by investigating its space of points. The group of transformations is discussed in Section 3.3.

Introductary remarks to Chapter 2

3.2.1 Projective Points

Imagine an eye situated at the origin of $\mathbb{R}^3$ looking at a fixed screen. As we mentioned in Subsection 3.1.1, each point of the screen corresponds to the ray of light that enters the eye from the point. This correspondence between points of the screen and rays of light through the origin is the clue that we need to define a space of points for our new geometry.



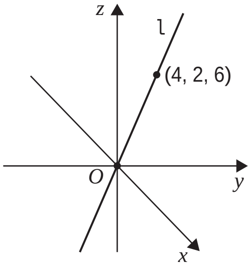


Rather than use the points of the screen directly, we use the rays of light that enable an eye to see the points from the origin. We can express this idea mathematically by defining a *projective point* to be a Euclidean line in $\mathbb{R}^3$ that passes through the origin. In order to avoid confusion with Euclidean points of $\mathbb{R}^3$, we write Point with a capital P whenever we mean a projective point.

It is important that you use the capital letter P in Point.

Definitions **A Point** (or **projective point)** is a line in $\mathbb{R}^3$ that passes through the origin of $\mathbb{R}^3$. The **real projective plane** $\mathbb{RP}^2$ is the set of all such Points.

In order to prove results in projective geometry algebraically, we need to have an algebraic notation that can be used to specify the Points of $\mathbb{RP}^2$. To do this, we use the fact that a line through the origin O in $\mathbb{R}^3$ is uniquely determined once we have specified a Euclidean point (other than O) that lies on . For example, there is a unique line in $\mathbb{R}^3$ through O and the point with Euclidean coordinates (4, 2, 6), so we can use these coordinates to specify a projective point. When doing this we write the coordinates in the form [4, 2, 6], with square brackets to indicate that the coordinates refer to a projective point.

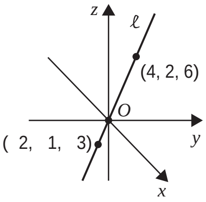


Definition The expression $[a, b, c]$, in which the numbers a, b, c are not all zero, represents the Point P in $\mathbb{RP}^2$ which consists of the unique line in $\mathbb{R}^3$ that passes through (0, 0, 0) and (a, b, c). We refer to $[a, b, c]$ as **homogeneous coordinates** of P. If (a, b, c) has position vector $\mathbf{v}$, then we often denote P by $[\mathbf{v}]$ and we say that P can be **represented** by $\mathbf{v}$.

Note that [0, 0, 0] is *not* defined.

Remark

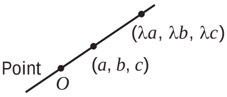
Often we abuse our notation slightly, by talking about the Point $[a, b, c]$ when strictly speaking we should say the Point with homogeneous coordinates $[a, b, c]$.



Notice that the homogeneous coordinates of a Point are not unique. For example, the Point with homogeneous coordinates [4, 2, 6] consists of a line that passes through (0, 0, 0) and (4, 2, 6). But this line also passes through (2, 1, 3), so [4, 2, 6] and [2, 1, 3] both represent the same Point.

In general, if (a, b, c) is any point on a line through the origin, and is any real number, then $(\ a,\ b,\ c)$ also lies on the line. Moreover, if (a, b, c) is not at the origin and $= 0$, then $(\ a,\ b,\ c)$ is not at the origin either. It follows that $[a, b, c]$ and $[\ a,\ b,\ c]$ both represent the same Point, for any $= 0$. We express this by writing

$$[a,b,c] = [\ a,\ b,\ c], \qquad \text{for any} \ = 0. \tag{1}$$



Conversely, if there is no non-zero real number such that

$$(a\ ,b\ ,c\ ) = (\ a,\ b,\ c),$$

then (a, b, c) and $(a\ ,b\ ,c\ )$ cannot lie on the same line through the origin, and so the homogeneous coordinates $[a, b, c]$ and $[a\ ,b\ ,c\ ]$ must represent different Points in $\mathbb{RP}^2$.

Example 1 Which of the following homogeneous coordinates represent the same Point in $\mathbb{RP}^2$ as [6, 3, 2]?

(a) [18, 9, 6] (b) [12, 6, 4] (c) $1, \frac{1}{2}, \frac{1}{3}$ (d) [1, 2, 3]

Solution

Throughout the solution we use equation (1):

$$[a, b, c] = [\ a,\ b,\ c],$$

for any $\ = 0$.

(a) This represents the same Point as [6, 3, 2], for if $\ = 3$, then

$$[18, 9, 6] = [6\ , 3\ , 2\ ] = [6, 3, 2].$$

(b) This represents a Point different from [6, 3, 2], for there is no that satisfies the simultaneous equations

$$12 = 6\ ,\quad 6 = 3\ , 4 = 2\ .$$

(c) This represents the same Point as [6, 3, 2], for if $\ = \frac{1}{6}$, then

$$1, \tfrac{1}{2}, \tfrac{1}{3}\quad = [6\ , 3\ , 2\ ] = [6, 3, 2].$$

(d) This represents a Point different from [6, 3, 2], for there is no that satisfies the simultaneous equations

$$1 = 6\ ,\quad 2 = 3\ ,\quad 3 = 2\ .$$ ☐

Problem 1 Which of the following homogeneous coordinates represent the same Point in $\mathbb{RP}^2$ as [1, 2, 3]?

(a) [2, 4, 6] (b) $[1, 2,\ \ 3]$ (c) $[\ \ 1,\ \ 2,\ \ 3]$ (d) [11, 12, 13]

At first sight it may seem rather unsatisfactory that the coordinates of a Point are not unique. However, this ambiguity can often be turned to our advantage. For example, if a calculation yields a Point of $\mathbb{RP}^2$ with fractional homogeneous coordinates such as $1, \frac{1}{2}, \frac{1}{3}$, then the rest of the calculation may be simpler if we clear the fractions and represent the Point by the integer homogeneous coordinates [6, 3, 2] instead.

Problem 2 For each of the following homogeneous coordinates, find integer homogeneous coordinates which represent the same Point.

(a) $\frac{3}{4}, \frac{1}{2},\ \ \frac{1}{8}$ (b) $0, 4, \frac{2}{3}$ (c) $\frac{1}{6},\ \ \frac{1}{3},\ \ \frac{1}{2}$

Given a collection of homogeneous coordinates, it is not always easy to spot those that represent the same Point. In such cases it is sometimes possible to rewrite the coordinates in a form that makes the comparison easier.

Example 2 Determine homogeneous coordinates of the form [*a*, *b*, 1] for the Points

$$[2,\ \ 1, 4],\qquad [4, 2, 8],\qquad [2\ \ ,\qquad , 4\ \ ],$$

$$[200, 100, 400],\qquad \frac{1}{2},\ \ \frac{1}{4},\ \ 1\ \ ,\qquad [6,\ \ 9,\ \ 12].$$

Hence decide which homogeneous coordinates represent the same Points.

Solution According to equation (1), a Point of $\mathbb{RP}^2$ is unchanged if its homogeneous coordinates are multiplied (or divided) by any non-zero real number. Since the third coordinate of each Point is non-zero, we may divide by this third coordinate to obtain homogeneous coordinates of the form [*a*, *b*, 1] as follows:

For, dividing by a non-zero number is equivalent to multiplying by the non-zero number 1 .

$$[2,\quad 1,4] = \tfrac{1}{2},\quad \tfrac{1}{4},1\ ; \qquad [4,2,8] = \tfrac{1}{2},\tfrac{1}{4},1\ ;$$

$$[2\ \ ,\qquad ,4\ \ ] = \tfrac{1}{2},\quad \tfrac{1}{4},1\ ; \qquad [200,100,400] = \tfrac{1}{2},\tfrac{1}{4},1\ ;$$

$$\tfrac{1}{2},\quad \tfrac{1}{4},\quad 1\ = \tfrac{1}{2},\tfrac{1}{4},1\ ; \qquad [6,\quad 9,\quad 12] = \tfrac{1}{2},\tfrac{3}{4},1\ .$$

Since $[a,b,1] = [a\ ,b\ ,1]$ if and only if $a = a$ and $b = b$, it follows that:

$[2,\quad 1,4]$ and $[2\ \ ,\qquad ,4\ \ ]$ represent the same Point;

$[4,2,8]$, $[200,100,400]$ and $\tfrac{1}{2},\quad \tfrac{1}{4},\quad 1$ represent the same Point;

$[6,\quad 9,\quad 12]$ represents none of the other Points. □

Notice that the method used in Example 2 works only if the third coordinates of all the Points are non-zero. If this is not the case, then you may still be able to apply the technique using the first or second coordinates.

Problem 3 Determine homogeneous coordinates of the form [1, *b*, *c*] for the Points

$$[2,3,\quad 5],\qquad [\quad 8,\quad 12,20],\qquad \overline{2},\quad \overline{3},\qquad \overline{5}\ ,$$

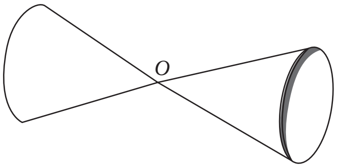
$$[4,\quad 6,10],\qquad [\quad 20,\quad 30,50],\qquad [74,148,0].$$

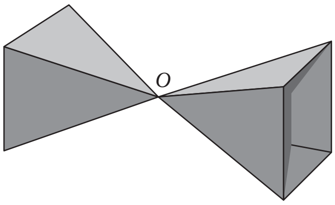
Hence decide which homogeneous coordinates represent the same Points.

Having defined projective points, we are now in a position to define a *projective figure.* Just as a figure in Euclidean geometry is defined to be a subset of $\mathbb{R}^2$, so figures in projective geometry are defined to be subsets of $\mathbb{RP}^2$.

Definition **A projective figure** is a subset of $\mathbb{RP}^2$.

Projective figures are just sets of lines in $\mathbb{R}^3$ that pass through the origin. Thus a double cone with a vertex at *O*, and a double square pyramid with a vertex at *O*, are both examples of projective figures, for they can both be formed from sets of lines that pass through the origin of $\mathbb{R}^3$.

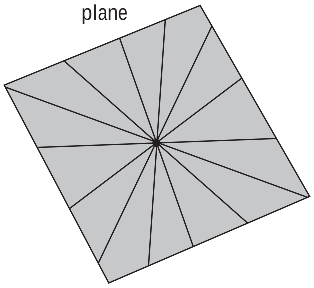


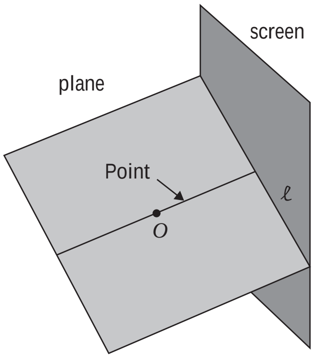


3.2.2 Projective Lines

A particularly simple type of projective figure is a plane through the origin. Such a plane is a projective figure because it can be formed from the set of all Points (lines through the origin of R^3) that lie on the plane. Since all but one of these Points can be thought of as rays of light that come from a line on a screen, it seems reasonable to define any plane through the origin to be a *projective line*.

The exception is the ray of light parallel to the screen. We shall discuss the significance of this ray later, in Subsection 3.2.3.





Just as we use ‘Point’ to refer to a ‘projective point’, so we use ‘Line’ to refer to a ‘projective line’. The use of a capital L avoids any confusion with lines in R^3.

Definitions **A Line** (or **projective line)** in RP^2 is a plane in R^3 that passes through the origin. Points in RP^2 are **collinear** if they lie on a Line.

Since a Line in RP^2 is simply a plane in R^3 that passes through the origin, it must consist of the set of Euclidean points (x, y, z) that satisfy an equation of the form

$$ax + by + cz = 0,$$

where a, b and c are real and not all zero. We can interpret this fact in terms of RP^2 as follows.

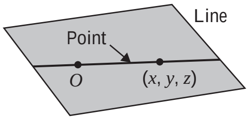
Theorem 1 The general equation of a Line in RP^2 is

$$ax + by + cz = 0, \tag{2}$$

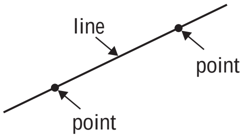
where a, b, c are real and not all zero.

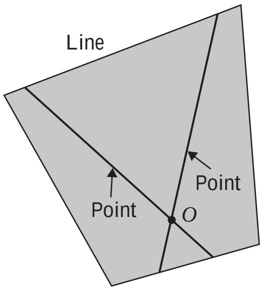
Remark

1. The equation of a Line is not unique, for, if $\lambda \neq 0$, then $\lambda ax + \lambda by + \lambda cz = 0$ is also an equation for the Line. We can use this fact to 'clear fractions' from the coefficients just as we did for the homogeneous coordinates of a Point.
2. From the figure in the margin it is clear that a Point lies on a Line, or a Line passes through a Point, if and only if the Point has homogeneous coordinates $[x, y, z]$ which satisfy the equation of the Line. For example, $[1, -1, 1]$ lies on the Line $3x + y - 2z = 0$, but $[0, 1, 3]$ does not.



In Euclidean geometry there is a unique line that passes through any two distinct points, as illustrated on the left of the figure below. Similarly, in projective geometry two distinct Points (lines through the origin) lie on a unique Line (plane through the origin).





We express this observation in the form of a theorem, as follows.

Theorem 2 Collinearity Property of $\mathbb{RP}^2$
Any two distinct Points of $\mathbb{RP}^2$ lie on a unique Line.

It is sometimes possible to find an equation for the Line that passes through two distinct Points of $\mathbb{RP}^2$ simply by spotting an equation of the form (2) that is satisfied by the homogeneous coordinates of both Points.

Example 3 For each of the following pairs of Points, write down an equation for the Line that passes through them.

(a) $[3, 2, 0]$ and $[3, 4, 0]$ (b) $[1, 2, 1]$ and $[3, 0, 3]$
(c) $[1, 0, 0]$ and $[0, 0, 1]$

Solution

(a) Both the Points have a z-coordinate equal to 0, so the homogeneous coordinates must satisfy the equation $z = 0$. This equation is of the form (2) with $a = 0, b = 0$ and $c = 1$, so it must be the required equation for the Line.

The equation $x = 3$ is not of the form (2), and so is not the equation of a Line.

(b) The homogeneous coordinates of both Points satisfy $x = z$. This equation is of the form (2) with $a = 1$, $b = 0$ and $c = -1$. It must therefore be the required equation for the Line.

(c) The homogeneous coordinates of both Points satisfy $y = 0$. This equation is of the form (2) with $a = 0$, $b = 1$ and $c = 0$, so it must be the required equation for the Line. □

Problem 4 For each of the following pairs of Points, write down an equation for the Line that passes through them.

(a) [0, 1, 0] and [0, 0, 1] (b) [2, 2, 3] and [3, 3, 7]

But how do we find an equation for a Line through two given Points in cases where it cannot be found by inspection? As an example, consider the Points $[2, -1, 4]$ and $[1, -1, 1]$. We could certainly substitute the values $x = 2$, $y = -1$, $z = 4$ and $x = 1$, $y = -1$, $z = 1$ into equation (2), to obtain the pair of simultaneous equations

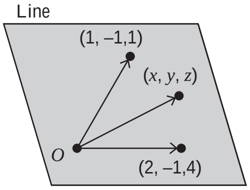
$$2a - b + 4c = 0,$$
$$a - b + c = 0.$$

Then subtracting twice the second equation from the first, we obtain $b = -2c$. So from the second equation it follows that $a = -3c$. If we set $c = -1$, say, then $a = 3$ and $b = 2$, so an equation for the Line is

$$3x + 2y - z = 0.$$

Of course, we could set c to have any non-zero value, but $c = -1$ keeps the calculation simple.

In this case the calculations are fairly straightforward, but there is an alternative method that is often simpler. Notice that the Line in $\mathbb{RP}^2$ through the Points $[2, -1, 4]$ and $[1, -1, 1]$ is the Euclidean plane in $\mathbb{R}^3$ that contains the position vectors of the points $(2, -1, 4)$ and $(1, -1, 1)$ in $\mathbb{R}^3$. A point (x, y, z) lies in this plane if and only if the vector (x, y, z) is a linear combination of the vectors $(2, -1, 4)$ and $(1, -1, 1)$; in other words, if and only if the vectors (x, y, z), $(2, -1, 4)$ and $(1, -1, 1)$ are linearly dependent.



But three vectors in $\mathbb{R}^3$ are linearly dependent if and only if the 3×3 determinant that has these vectors as its rows is zero. It follows that (x, y, z) lies in the plane containing the position vectors $(2, -1, 4)$ and $(1, -1, 1)$ if and only if

$$\begin{vmatrix} x & y & z \\ 2 & -1 & 4 \\ 1 & -1 & 1 \end{vmatrix} = 0.$$

Translating this statement back into a statement concerning $\mathbb{RP}^2$, we deduce that the Point $[x, y, z]$ lies on the Line through the Points $[2, -1, 4]$ and $[1, -1, 1]$ if and only if

$$\begin{vmatrix} x & y & z \\ 2 & -1 & 4 \\ 1 & -1 & 1 \end{vmatrix} = 0.$$

Expanding this determinant in terms of the entries in its first row, we obtain

$$\begin{vmatrix} x & y & z \\ 2 & -1 & 4 \\ 1 & -1 & 1 \end{vmatrix} = x\begin{vmatrix} -1 & 4 \\ -1 & 1 \end{vmatrix} - y\begin{vmatrix} 2 & 4 \\ 1 & 1 \end{vmatrix} + z\begin{vmatrix} 2 & -1 \\ 1 & -1 \end{vmatrix}$$

$$= 3x + 2y - z.$$

Hence an equation for the required Line in $\mathbb{RP}^2$ is

$$3x + 2y - z = 0. \tag{3}$$

Remark

It is always sensible to check your arithmetic by checking that the two given Points actually lie on the Line that you have found. For instance, the answer above is correct, since equation (3) is a homogeneous linear equation in x, y and z, and the equation is satisfied by $x = 2$, $y = -1$, $z = 4$ and by $x = 1$, $y = -1$, $z = 1$.

We may summarize the above method in the form of a strategy, as follows.

Strategy To determine an equation for the Line in $\mathbb{RP}^2$ through the Points $[d, e, f]$ and $[g, h, k]$:

1. write down the equation

$$\begin{vmatrix} x & y & z \\ d & e & f \\ g & h & k \end{vmatrix} = 0;$$

2. expand the determinant in terms of the entries in its first row to obtain the required equation in the form $ax + by + cz = 0$.

Example 4 Find an equation for the Line that passes through the Points $[1, 2, 3]$ and $[2, -1, 4]$.

Solution An equation for the Line is

$$\begin{vmatrix} x & y & z \\ 1 & 2 & 3 \\ 2 & -1 & 4 \end{vmatrix} = 0.$$

Now

$$\begin{vmatrix} x & y & z \\ 1 & 2 & 3 \\ 2 & -1 & 4 \end{vmatrix} = x\begin{vmatrix} 2 & 3 \\ -1 & 4 \end{vmatrix} - y\begin{vmatrix} 1 & 3 \\ 2 & 4 \end{vmatrix} + z\begin{vmatrix} 1 & 2 \\ 2 & -1 \end{vmatrix}$$

$$= 11x + 2y - 5z.$$

An equation for the Line is therefore

$$11x + 2y \quad 5z = 0. \qquad \square$$

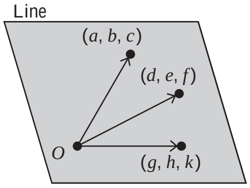
You can easily check that the Points [1, 2, 3] and [2, 1, 4] lie on this Line.

Problem 5 Determine an equation for each of the following Lines in RP^2:

(a) the Line through the Points [2, 5, 4] and [3, 1, 7];
(b) the Line through the Points [2, 4, 5] and [3, 2, 4].

A similar technique can be used to check whether three given Points are collinear. Indeed, three Points $[a, b, c]$, $[d, e, f]$, $[g, h, k]$ are collinear if and only if the position vectors of the points (a, b, c), (d, e, f), (g, h, k) are linearly dependent; that is, if and only if

$$\begin{matrix} a & b & c \\ d & e & f \\ g & h & k \end{matrix} = 0.$$



Example 5 Determine whether the Points [2, 1, 3], [1, 2, 1] and [1, 4, 3] are collinear.

Solution We have

$$\begin{aligned}\begin{matrix} 2 & 1 & 3 \\ 1 & 2 & 1 \\ 1 & 4 & 3 \end{matrix} &= 2\begin{matrix} 2 & 1 \\ 4 & 3 \end{matrix} \quad 1\begin{matrix} 1 & 1 \\ 1 & 3 \end{matrix} + 3\begin{matrix} 1 & 2 \\ 1 & 4 \end{matrix} \\ &= 2(\; 6 \quad 4) \quad (\; 3 + 1) + 3(4 + 2) \\ &= \quad 20 + 2 + 18 \\ &= 0.\end{aligned}$$

Since this is zero it follows that [2, 1, 3], [1, 2, 1] and [1, 4, 3] are collinear. □

We summarize the method of Example 5 in the following strategy.

Strategy To determine whether three Points $[a, b, c]$, $[d, e, f]$, $[g, h, k]$ are collinear:

1. evaluate the determinant $\begin{matrix} a & b & c \\ d & e & f \\ g & h & k \end{matrix}$;
2. the Points $[a, b, c]$, $[d, e, f]$, $[g, h, k]$ are collinear if and only if this determinant is zero.

Problem 6 Determine whether the following sets of Points are collinear.

(a) $[1,2,3], [1,1,-2], [2,1,-9]$ (b) $[1,2,-1], [2,1,0], [0,-1,3]$

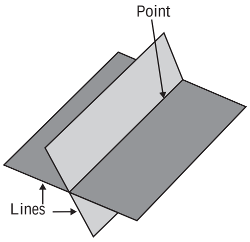
Before rushing to solve a problem using determinants, you should always stop to see if you can solve the problem more easily by inspection. For example, suppose that you are asked to check whether the Points [1, 0, 0], [0, 1, 0], [1, 1, 1] are collinear. Clearly, [1, 0, 0] and [0, 1, 0] lie on the Line $z = 0$, whereas [1, 1, 1] does not, so the Points are not collinear.

Problem 7 Verify that no three of the Points [1, 0, 0], [0, 1, 0], [0, 0, 1] and [1, 1, 1] are collinear.

The Points that you considered in Problem 7 play an important part in our development of the theory of projective geometry, so we give them special names.

Definitions The Points [1, 0, 0], [0, 1, 0], [0, 0, 1] are known as the **triangle of reference.** The Point [1, 1, 1] is called the **unit Point.**

Next, observe that any two distinct Lines necessarily meet at a unique Point. Indeed, a Line in $\mathbb{RP}^2$ is simply a plane in $\mathbb{R}^3$ that passes through the origin, and two distinct planes through the origin of $\mathbb{R}^3$ must intersect in a unique Euclidean line through the origin; that is, in a Point. This is very different to the situation in Euclidean geometry where parallel lines do not meet.



Theorem 3 Incidence Property of $\mathbb{RP}^2$
Any two distinct Lines in $\mathbb{RP}^2$ intersect in a unique Point of $\mathbb{RP}^2$.

This result neatly complements Theorem 2, the *Collinearity Property* of $\mathbb{RP}^2$.

We can determine the Point of intersection of two Lines simply by solving the equations of the two Lines as a pair of simultaneous equations.

Example 6 Determine the Point of intersection of the Lines in $\mathbb{RP}^2$ with equations $x + 6y - 5z = 0$ and $x - 2y + z = 0$.

We know that there is a unique Point of intersection, by Theorem 3.

Solution At the Point of intersection $[x, y, z]$ of the two Lines, we have

$$x + 6y - 5z = 0,$$
$$x - 2y + z = 0.$$

Subtracting the second equation from the first, we obtain

$$8y - 6z = 0,$$

so that $y = \frac{3}{4}z$. Substituting this into the second equation, we obtain $x = \frac{1}{2}z$.

It follows that the Point of intersection has homogeneous coordinates $\frac{1}{2}z, \frac{3}{4}z, z$ which we can rewrite in the form $\frac{1}{2}, \frac{3}{4}, 1$ or [2, 3, 4]. □

Note that $z = 0$, since [0, 0, 0] are not allowed as homogeneous coordinates.

Problem 8 Determine the Point of intersection of each of the following pairs of Lines in RP^2:

(a) the Lines with equations $x \quad y \quad z = 0$ and $x + 5y + 2z = 0$;
(b) the Lines with equations $x + 2y \quad z = 0$ and $2x + y \quad 4z = 0$.

Problem 9 Determine the Point of RP^2 at which the Line through the Points $[1, 2, \quad 3]$ and $[2, \quad 1, 0]$ meets the Line through the Points $[1, 0, \quad 1]$ and [1, 1, 1].

In some cases we can write down the Point at which two Lines intersect without having to solve any equations at all. For example, the Lines with equations $x = 0$ and $y = 0$ clearly meet at the Point [0, 0, 1].

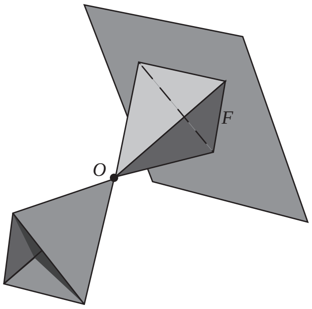
Problem 10 Determine the Point of RP^2 at which the Line through the Points [1, 0, 0] and [0, 1, 0] meets the Line through the Points [0, 0, 1] and [1, 1, 1].

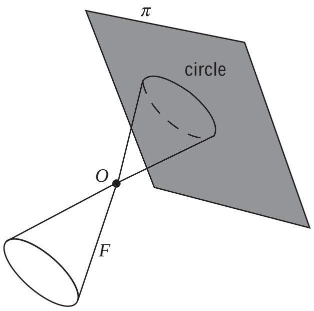
3.2.3 Embedding Planes

So far we have used three-dimensional space to develop the theory of projective geometry. In practice, however, we want to use projective geometry to study two-dimensional figures in a plane. In order to do this, we now investigate a way of associating figures in a plane with figures in RP^2, and vice versa.

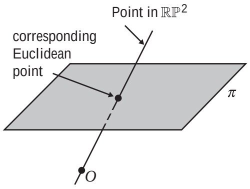
Suppose that a plane contains a figure F. We can place into R^3, making sure that it does not pass through the origin, and then construct a corresponding projective figure by drawing in all the Points of RP^2 that pass through the points of F. For example, if F is the triangle shown on the left below, then the corresponding projective figure is a double triangular pyramid. Note that if we change the position of in R^3, we obtain a different projective figure corresponding to F.

It is a *double* pyramid because the Points which make up the pyramid are lines that emerge from the origin in *both* directions.



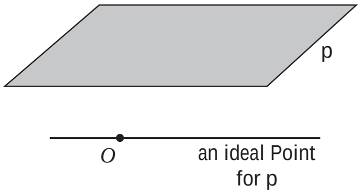


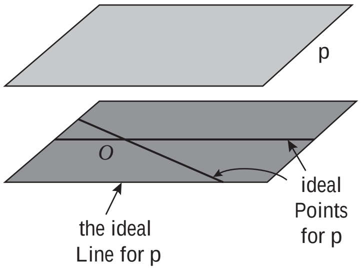
Conversely, suppose that we start with a projective figure F. The corresponding Euclidean figure in consists of the Euclidean points where the Points of F pierce . For example, if F is a double cone whose axis is at right angles to the embedding plane, as shown on the right above, then the corresponding Euclidean figure is a circle. Note that if we change the position of in $\mathbb{R}^3$, we obtain a different plane figure corresponding to F.



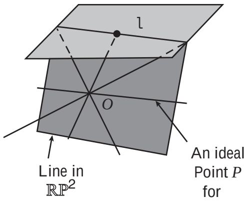
This correspondence between projective figures and Euclidean figures works well provided that each Point of the projective figure pierces the plane , as shown in the margin. Unfortunately, any Point of $\mathbb{RP}^2$ that consists of a line through the origin *parallel* to does not pierce , and so cannot be associated with a point of . Such a Point is called an **ideal Point** for .

All the ideal Points for lie on a plane through O parallel to . This plane is a projective line known as the **ideal Line** for .





How can we represent a projective figure on if the figure includes some of the ideal Points for ? As a simple example, consider the Line illustrated in the margin. This is a projective figure which intersects in a line . Every Point of the Line pierces the embedding plane at a point of except for the ideal Point P which cannot be represented on . In order to represent the Line completely, we need not only the line but also the ideal Point P. In other words, the Line is represented by $\{P\}$.



In general, a projective figure can be represented by a figure in provided that we are prepared to include a subset of Points taken from the ideal Line for . In order to allow for these additional ideal Points, we introduce the concept of an *embedding plane.*

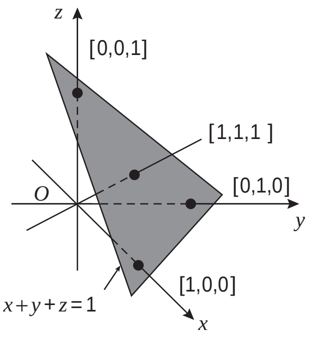
Definitions An **embedding plane** is a plane, , which does not pass through the origin, together with the set of all ideal Points for . The plane in $\mathbb{R}^3$ with equation $z = 1$ is called the **standard embedding plane**. The mapping of $\mathbb{RP}^2$ into the standard embedding plane is called the **standard embedding** of $\mathbb{RP}^2$.

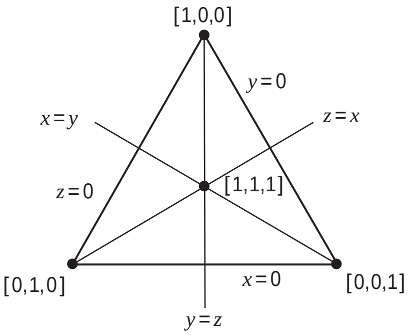
We frequently use to denote both a plane and an embedding plane, but no confusion should arise.

We may summarize the above discussion by saying that for a given embedding plane, every projective figure in $\mathbb{RP}^2$ corresponds to a figure in the embedding plane, and vice versa. The figure in the embedding plane may include some ideal Points but is otherwise a Euclidean figure.

If two embedding planes are parallel to each other, the same Points of $\mathbb{RP}^2$ correspond to ideal Points of the embeddings; whereas, if the embedding planes are not parallel, different Points of $\mathbb{RP}^2$ correspond to ideal Points of the two embedding planes.

Once we have represented a projective figure in an embedding plane, we can investigate the relationship between its Points and Lines without having to refer to three-dimensional space at all. For example, consider the representation of the triangle of reference and unit Point on the embedding plane $x + y + z = 1$, shown on the left below. If we extract the embedding plane from $\mathbb{R}^3$, as shown on the right, we can use the algebraic theory developed earlier to write down an equation for the Line through any two given Points, without reference to $\mathbb{R}^3$.

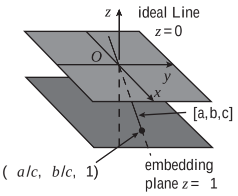




Similarly, we can use the algebraic techniques to calculate the homogeneous coordinates of the Point of intersection of any two given Lines.

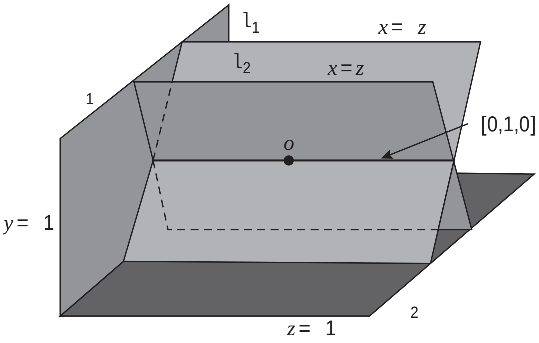
> **Problem 11** On the right-hand diagram above, insert the homogeneous coordinates of the Points where the Lines through [1, 1, 1] meet the sides of the triangle of reference.

Any plane may be used as an embedding plane provided that it does not pass through the origin. For example, if we take to be the plane $z =$ 1, then the ideal Line for has equation $z = 0$, and the ideal Points are Points of the form $[a, b, 0]$, where a and b are not both zero. Any other Point $[a, b, c]$ has $c = 0$ and can therefore be represented in by the Euclidean point(a/c, b/c, 1).



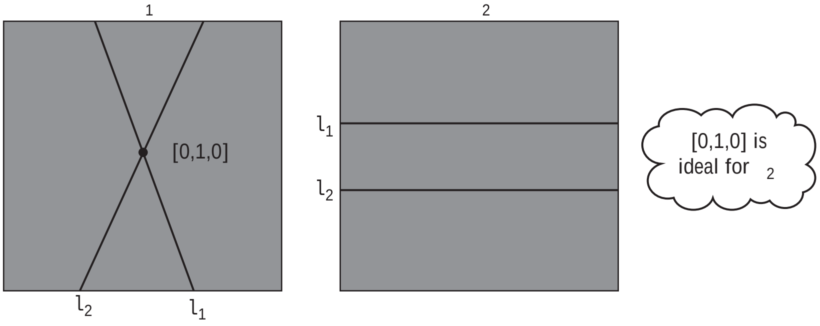
> **Problem 12** Let be the embedding plane $y =$ 1. Describe the ideal Points for , and specify the Euclidean point of which represents the Point [2, 4, 6].

Although we can choose any embedding plane to represent figures of $\mathbb{RP}^2$, the representation does depend on the choice. For example, suppose that $_1$ is the embedding plane $y = 1$, and that $_2$ is the embedding plane $z = 1$. Now consider the projective figure which consists of two Lines $_1$ and $_2$ with equations $x = z$ and $x = z$, respectively. These Lines intersect at the Point [0, 1, 0].



On the embedding plane $_1$ the Lines $_1$ and $_2$ are represented by two lines that can be seen to meet at the point corresponding to [0, 1, 0]. However, on the embedding plane $_2$ the Point of intersection [0, 1, 0] is an ideal Point and so the Lines $_1$ and $_2$ are represented by parallel lines that do not appear to meet. The contrast between the two representations of $_1$ and $_2$ is particularly striking if we extract the two embedding planes from $\mathbb{R}^3$ and lay them side by side, as follows.

This is the mathematical fact which explains why artists sometimes draw parallel lines (such as railroad lines) as intersecting lines.



This example illustrates that Lines which appear to be parallel in one embedding plane may not appear to be parallel in another embedding plane. In the next section you will see that the transformations of projective geometry are chosen so as to ensure that the projective properties of a figure are unaffected by the choice of embedding plane. Since parallelism does depend on the choice of embedding plane, it cannot be a projective property, so the concept of parallel Lines is meaningless in projective geometry.

3.2.4 An equivalent definition of Projective Geometry

In our work on projective geometry, we have used Euclidean points in a plane in $\mathbb{R}^3$ to construct the projective points (Points) of the geometry $\mathbb{RP}^2$, homogeneous coordinates for those Points, and projective lines (Lines).

Equivalently, we could have defined $\mathbb{RP}^2$ as the set of ordered triples $[a, b, c]$, where a, b, c are real and not all zero, with the convention that we regard [a, b, c] and $[a, b, c]$ (where $= 0$) as the same Point in the geometry. We would then have defined projective lines (Lines) as the set of points $[x, y, z]$ in $\mathbb{RP}^2$ that satisfy an equation of the form $ax + by + cz = 0$, where a, b, c are real and not all zero, Then we would continue to develop the theory of projective geometry in the same way as we have done here.

However, we chose to start our work by looking at a model of $\mathbb{RP}^2$ obtained by using an embedding plane in $\mathbb{R}^3$ that does not pass through the origin. We modeled the projective points $[a, b, c]$ by the Euclidean lines through the origin and the corresponding Euclidean points (a, b, c), plus points at infinity (the ideal Points); and we modeled the projective lines by Euclidean planes through the origin, For convenience, we chose often to use Euclidean points (a, b, c) on a given embedding plane to describe the Euclidean model.

Any plane that does not pass through the origin in $\mathbb{R}^3$ will serve as an embedding plane.

The formal method of defining projective geometry, though, is less intuitive than the description motivated by the $\mathbb{R}^3$ model!

3.3 Projective Transformations

3.3.1 The Group of Projective Transformations

By now you should be familiar with the idea that a geometry consists of a space of points together with a group of transformations which act on that space.

Having introduced the space of projective points $\mathbb{RP}^2$ in Section 3.2, we are now in a position to describe the transformations of $\mathbb{RP}^2$. First we shall define the transformations algebraically, then we give a geometrical interpretation of the transformations using the ideas of perspectivity introduced in Section 3.1, and finally meet the Fundamental Theorem of Projective Geometry.

Recall that a point of $\mathbb{R}^3$ (other than the origin) on an embedding plane (that does not pass through the origin) has coordinates $\mathbf{x} = (x, y, z)$ with respect to the standard basis of $\mathbb{R}^3$, and homogeneous coordinates of the corresponding Point $[\mathbf{x}]$ in $\mathbb{RP}^2$ (which represents the points $\{\ \mathbf{x} : \quad \mathbb{R}\}$) are [x, y, z] for some real $= 0$. Since the Points of $\mathbb{RP}^2$ are just lines through the origin of $\mathbb{R}^3$, we need a group of transformations that map the lines through the origin of $\mathbb{R}^3$ onto the lines through the origin of $\mathbb{R}^3$. Suitable transformations of $\mathbb{R}^3$ that do this are the invertible linear transformations.

Subsection 3.2.1

If **A** is the matrix of an invertible linear transformation of $\mathbb{R}^3$ to itself, the transformation maps points $\mathbf{x} = (x, y, z)$ of $\mathbb{R}^3$ to points $\mathbf{Ax}$ of $\mathbb{R}^3$; then the *projective transformation* with matrix **A** maps Points $[\mathbf{x}]$ of $\mathbb{RP}^2$ to Points $[\mathbf{Ax}]$ of $\mathbb{RP}^2$. This suggests that we define the transformations of projective geometry as follows.

In fact, any continuous transformation of $\mathbb{RP}^2$ to itself that maps Lines to Lines and that preserves incidences of Lines corresponds to an invertible linear transformation of $\mathbb{R}^3$. We omit a proof of this fact.

Definitions A **projective transformation** of $\mathbb{RP}^2$ is a function $t : \mathbb{RP}^2 \to \mathbb{RP}^2$ of the form

$$t : [\mathbf{x}] \mapsto [\mathbf{Ax}],$$

where **A** is an invertible 3×3 matrix. We say that **A** is a matrix **associated** with t. The set of all projective transformations of $\mathbb{RP}^2$ is denoted by $P(2)$.

Example 1 Show that the function $t : \mathbb{RP}^2 \to \mathbb{RP}^2$ defined by

$$t : [x, y, z] \mapsto [2x + z, -x + 2y - 3z, x - y + 5z]$$

is a projective transformation, and find the image of $[1, 2, 3]$ under t.

Solution The transformation t has the form $t : [\mathbf{x}] \mapsto [\mathbf{Ax}]$, where $\mathbf{x} = (x, y, z)$ and

$$\mathbf{A} = \begin{pmatrix} 2 & 0 & 1 \\ -1 & 2 & -3 \\ 1 & -1 & 5 \end{pmatrix}.$$

Now

$$\begin{aligned} \det \mathbf{A} &= \begin{vmatrix} 2 & 0 & 1 \\ -1 & 2 & -3 \\ 1 & -1 & 5 \end{vmatrix} \\ &= 2(10 - 3) - 0 + (1 - 2) \\ &= 13 \neq 0. \end{aligned}$$

So **A** is invertible. It follows that t is a projective transformation.

We have

$$t([1, 2, 3]) = [2 + 3, -1 + 4 - 9, 1 - 2 + 15] = [5, -6, 14]. \qquad \square$$

Problem 1 Decide which of the following functions t from $\mathbb{RP}^2$ to itself are projective transformations. For those that are projective transformations, write down a matrix associated with t.

(a) $t : [x, y, z] \mapsto [-2y + 3z, -x + 5y - z, -3x]$
(b) $t : [x, y, z] \mapsto [x - 7y + 4z, -x + 5y - z, x - 9y + 7z]$
(c) $t : [x, y, z] \mapsto [x - 1 + z, 2y - 4z + 5, 2x]$

Problem 2 Let t be the projective transformation associated with the matrix.

$$\mathbf{A} = \begin{matrix} 1 & 1 & 1 \\ 1 & 2 & 1 \\ 4 & 3 & 4 \end{matrix}.$$

Determine the image under t of each of the following Points.

(a) $[1, 2, \quad 1]$ (b) $[1, 0, 0]$ (c) $[0, 1, 0]$
(d) $[0, 0, 1]$ (e) $[1, 1, 1]$

Since we can multiply the homogeneous coordinates of Points in $\mathbb{RP}^2$ by any non-zero real number without altering the Point itself, it follows that if **A** is a matrix associated with a particular projective transformation then so is the matrix **A**, provided that $= 0$. For example, another matrix associated with the transformation in Example 1 is

$$\mathbf{B} = \begin{matrix} 4 & 0 & 2 \\ 2 & 4 & 6 \\ 2 & 2 & 10 \end{matrix},$$

for we have $\mathbf{B} = \quad 2\mathbf{A}$.

Problem 3 Write down a matrix with top left-hand entry $\frac{1}{2}$ which is associated with the transformation in Example 1.

Before we can use the projective transformations to define projective geometry, we must first check that they form a group.

Theorem 1 The set of projective transformations $P(2)$ forms a group under the operation of composition of functions.

Recall that a similar result holds for affine transformations.

Proof We check that the four group axioms hold.

G1 CLOSURE Let t_1 and t_2 be projective transformations defined by

$$t_1 : [\mathbf{x}] \quad [\mathbf{A_1x}] \quad \text{and} \quad t_2 : [\mathbf{x}] \quad [\mathbf{A_2x}],$$

where $\mathbf{A}_1$ and $\mathbf{A}_2$ are invertible 3×3 matrices. Then

$$\begin{aligned} t_1 \quad t_2([\mathbf{x}]) &= t_1(t_2([\mathbf{x}])) \\ &= t_1([\mathbf{A_2x}]) \\ &= [(\mathbf{A_1A_2})\mathbf{x}]. \end{aligned}$$

Since $\mathbf{A}_1$ and $\mathbf{A}_2$ are invertible, it follows that $\mathbf{A_1A_2}$ is invertible. So by definition $t_1 \quad t_2$ is a projective transformation.

G2 IDENTITY Let $i : \mathbb{RP}^2 \quad \mathbb{RP}^2$ be the transformation defined by

$$i : [\mathbf{x}] \quad [\mathbf{Ix}],$$

where **I** is the 3×3 identity matrix; this is a projective transformation, since **I** is invertible.

Let t: $\mathbb{RP}^2 \to \mathbb{RP}^2$ be an arbitrary projective transformation, defined by $t:[\mathbf{x}] \mapsto [\mathbf{Ax}]$, for some invertible 3 × 3 matrix $\mathbf{A}$. Then for any $[\mathbf{x}] \in \mathbb{RP}^2$,

$$t \circ i([\mathbf{x}]) = [\mathbf{A}(\mathbf{Ix})] = [\mathbf{Ax}]$$

and

$$i \circ t([\mathbf{x}]) = [\mathbf{I}(\mathbf{Ax})] = [\mathbf{Ax}].$$

Thus $t \circ i = i \circ t = t$. Hence i is the identity transformation.

G3 INVERSES Let $t : \mathbb{RP}^2 \to \mathbb{RP}^2$ be an arbitrary projective transformation defined by

$$t: [\mathbf{x}] \mapsto [\mathbf{Ax}],$$

for some invertible 3 × 3 matrix $\mathbf{A}$. Then we can define another projective transformation t' : $\mathbb{RP}^2 \to \mathbb{RP}^2$ by

$$t' : [\mathbf{x}] \mapsto [\mathbf{A}^{-1}\mathbf{x}].$$

Now, for each $[\mathbf{x}] \in \mathbb{RP}^2$, we have

$$t \circ t'([\mathbf{x}]) = \mathbf{t}([\mathbf{A}^{-1}\mathbf{x}]) = [\mathbf{A}(\mathbf{A}^{-1}\mathbf{x})] = [\mathbf{x}]$$

and

$$t' \circ t([\mathbf{x}]) = t'([\mathbf{Ax}]) = [\mathbf{A}^{-1}(\mathbf{Ax})] = [\mathbf{x}].$$

Thus t' is an inverse for t.

G4 ASSOCIATIVITY Composition of functions is always associative.

It follows that the set of projective transformations $P(2)$ forms a group.

The above proof shows that if t_1 and t_2 are projective transformations with associated matrices $\mathbf{A}_1$ and $\mathbf{A}_2$, respectively, then $t_1 \circ t_2$ is a projective transformation with an associated matrix $\mathbf{A}_1\mathbf{A}_2$. We therefore have the following strategy for composing projective transformations.

Strategy To compose two projective transformations t_1 and t_2:

1. write down matrices $\mathbf{A}_1$ and $\mathbf{A}_2$ associated with t_1 and t_2;
2. calculate $\mathbf{A}_1\mathbf{A}_2$;
3. write down the composite $t_1 \circ t_2$ with which $\mathbf{A}_1\mathbf{A}_2$ is associated.

The proof also shows that if t is a projective transformation with an associated matrix $\mathbf{A}$, then t^{-1} is a projective transformation with associated matrix $\mathbf{A}^{-1}$. We therefore have the following strategy for calculating the inverse of a projective transformation.

See Appendix 2 for one method to calculate $\mathbf{A}^{-1}$.

Strategy To find the inverse of a projective transformation t:

1. write down a matrix $\mathbf{A}$ associated with t;
2. calculate $\mathbf{A}^{-1}$;
3. write down the inverse t^{-1} with which $\mathbf{A}^{-1}$ is associated.

Example 2 Let t_1 and t_2 be projective transformations defined by

$$t_1 : [x, y, z] \mapsto [x + z, x + y + 3z, -2x + z],$$
$$t_2 : [x, y, z] \mapsto [2x, x + y + z, 4x + 2y].$$

Determine the projective transformations $t_2 \circ t_1$ and t_1^{-1}.

Solution The transformations t_1 and t_2 have associated matrices

$$\mathbf{A}_1 = \begin{pmatrix} 1 & 0 & 1 \\ 1 & 1 & 3 \\ -2 & 0 & 1 \end{pmatrix} \quad \text{and} \quad \mathbf{A}_2 = \begin{pmatrix} 2 & 0 & 0 \\ 1 & 1 & 1 \\ 4 & 2 & 0 \end{pmatrix},$$

respectively. It follows that $t_2 \circ t_1$ has an associated matrix

$$\mathbf{A}_2\mathbf{A}_1 = \begin{pmatrix} 2 & 0 & 0 \\ 1 & 1 & 1 \\ 4 & 2 & 0 \end{pmatrix} \begin{pmatrix} 1 & 0 & 1 \\ 1 & 1 & 3 \\ -2 & 0 & 1 \end{pmatrix} = \begin{pmatrix} 2 & 0 & 2 \\ 0 & 1 & 5 \\ 6 & 2 & 10 \end{pmatrix},$$

so

$$t_2 \circ t_1 : [x, y, z] \mapsto [2x + 2z, y + 5z, 6x + 2y + 10z].$$

Next, t_1^{-1} has an associated matrix $\mathbf{A}_1^{-1}$ given by

$$\mathbf{A}_1^{-1} = \begin{pmatrix} \frac{1}{3} & 0 & -\frac{1}{3} \\ -\frac{7}{3} & 1 & -\frac{2}{3} \\ \frac{2}{3} & 0 & \frac{1}{3} \end{pmatrix};$$

a simpler matrix associated with t_1^{-1} is then

$$\begin{pmatrix} 1 & 0 & -1 \\ -7 & 3 & -2 \\ 2 & 0 & 1 \end{pmatrix},$$

so

$$t_1^{-1} : [x, y, z] \mapsto [x - z, -7x + 3y - 2z, 2x + z].$$ □

Problem 4 Let t_1 and t_2 be projective transformations defined by

$$t_1 : [x, y, z] \mapsto [2x + y, -x + z, y + z],$$
$$t_2 : [x, y, z] \mapsto [5x + 8y, 3x + 5y, 2z].$$

Determine the projective transformations $t_1 \circ t_2$ and t_1^{-1}.

Having shown that the set of projective transformations forms a group under composition of functions, we can now define **projective geometry** to be the study of those properties of figures in $\mathbb{RP}^2$ that are preserved by projective transformations. Those properties that are preserved by projective transformations are known as **projective properties.**

3.3.2 Some Properties of Projective Transformations

We now check two important properties of projective transformations, namely, that they preserve collinearity and incidence.

A Line in $\mathbb{RP}^2$ is a plane in $\mathbb{R}^3$ that passes through the origin. It therefore consists of the set of points (x, y, z) of $\mathbb{R}^3$ that satisfy an equation of the form

$$ax + by + cz = 0,$$

where a, b and c are not all zero. We can write this condition equivalently in the matrix form $\mathbf{Lx} = 0$, where $\mathbf{L}$ is the non-zero row matrix $(a\ b\ c)$ and $\mathbf{x} = (x\ y\ z)^T$.

Now let t be a projective transformation defined by $t : [\mathbf{x}] \mapsto [\mathbf{Ax}]$, where $\mathbf{A}$ is an invertible 3×3 matrix, and let $[\mathbf{x}]$ be an arbitrary Point on the Line $\mathbf{Lx} = 0$. Then the image of $[\mathbf{x}]$ under t is a Point $[\mathbf{x}']$ where $\mathbf{x}' = \mathbf{Ax}$. Since $\mathbf{x}$ satisfies the equation $\mathbf{Lx} = 0$, it follows that $\mathbf{x}'$ satisfies $\mathbf{L}(\mathbf{A}^{-1}\mathbf{x}') = 0$, or $(\mathbf{LA}^{-1})\mathbf{x}' = 0$. Dropping the dash, we conclude that the image of the Line $\mathbf{Lx} = 0$ under t is the Line with equation

$$\left(\mathbf{LA}^{-1}\right)\mathbf{x} = 0.$$

Here, $\mathbf{LA}^{-1}$ is non-zero, for if

$$\mathbf{LA}^{-1} = \mathbf{0},$$

then

$$\mathbf{0} = \left(\mathbf{LA}^{-1}\right)\mathbf{A}$$

$$= \mathbf{L}\left(\mathbf{A}^{-1}\mathbf{A}\right) = \mathbf{L},$$

which is not the case.

Since the image of a Line in $\mathbb{RP}^2$ is a Line, it follows that collinearity is preserved under a projective transformation.

Notice that if $\mathbf{B}$ is any matrix associated with t^{-1}, then $\mathbf{B} = \lambda\mathbf{A}^{-1}$ for some non-zero real number λ, and so $\left(\mathbf{LA}^{-1}\right)\mathbf{x} = 0$ if and only if $(\mathbf{LB})\mathbf{x} = 0$. It follows that the image of the Line can equally well be written as $(\mathbf{LB})\mathbf{x} = 0$. (For instance, since $\mathbf{A}^{-1} = \operatorname{adj}(\mathbf{A}) / \det(\mathbf{A})$ so that t^{-1} also has $\operatorname{adj}(\mathbf{A})$ as an associated matrix, we can express the image of the Line as $(\mathbf{L}\operatorname{adj}(\mathbf{A}))\mathbf{x} = 0$.)

We therefore summarize the above discussion in the form of a strategy, as follows.

Strategy To find the image of a Line

$$ax + by + cz = 0$$

under a projective transformation $t : [\mathbf{x}] \mapsto [\mathbf{AX}]$:

1. write the equation of the Line in the form $\mathbf{Lx} = 0$, where $\mathbf{L}$ is the matrix $(a\ b\ c)$;
2. find a matrix $\mathbf{B}$ associated with t^{-1};
3. write down the equation of the image as $(\mathbf{LB})\mathbf{x} = 0$.

Example 3 Find the image of the Line $2x + y - 3z = 0$ under the projective transformation t_1 defined by

$$t_1 : [x, y, z] \qquad [x + z, x + y + 3z, \quad 2x + z].$$

Solution The equation of the Line can be written in the form $\mathbf{L}\mathbf{x} = 0$, where

$$\mathbf{L} = (2 \quad 1 \qquad 3).$$

In Example 2 we showed that $t_1^{\ \ 1}$ has an associated matrix

$$\mathbf{B} = \begin{matrix} 1 & 0 & 1 \\ 7 & 3 & 2 \\ 2 & 0 & 1 \end{matrix} .$$

So

$$\mathbf{LB} = (2 \quad 1 \quad 3) \begin{matrix} 1 & 0 & 1 \\ 7 & 3 & 2 \\ 2 & 0 & 1 \end{matrix} = (\quad 11 \quad 3 \quad 7).$$

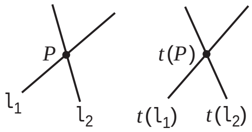
It follows that the required image has equation

$$11x + 3y \quad 7z = 0.$$ □

Problem 5 Find the image of the Line $x + 2y \quad z = 0$ under the projective transformation t_1 defined by

$$t_1 : [x, y, z] \qquad [2x + y, \quad x + z, y + z].$$

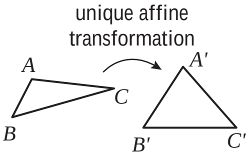
Next, we consider the incidence property. If two Lines intersect at the Point P, then P lies on both Lines. So if t is a projective transformation, then $t(P)$ lies on the images of both Lines. It follows that the image under t of the Point of intersection of the two Lines is the Point of intersection of the images of the two Lines. In other words, incidence is also preserved under a projective transformation.



Theorem 2 Collinearity and incidence are both projective properties.

3.3.3 Fundamental Theorem of Projective Geometry

In Chapter 2 we discussed the Fundamental Theorem of Affine Geometry which states that given any two sets of three non-collinear points of $\mathbb{R}^2$ there is a unique affine transformation which maps the points in one set to the corresponding points in the other set. So an affine transformation is uniquely determined by its effect on any given triangle.



In this subsection we explore an analogous result for projective geometry known as the *Fundamental Theorem of Projective Geometry*. We begin by asking you to tackle the following problem.

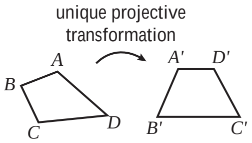
Problem 6 Let t_1 and t_2 be the projective transformations with associated matrices

$$\mathbf{A}_1 = \begin{matrix} 4 & 1 & 1 \\ 3 & 2 & 1 \\ 4 & 2 & 1 \end{matrix} \quad \text{and} \quad \mathbf{A}_2 = \begin{matrix} 8 & 6 & 2 \\ 3 & 4 & 7 \\ 6 & 0 & 4 \end{matrix} ,$$

respectively. Find the images of the Points $[1, -1, 1]$, $[1, -2, 2]$ and $[-1, 2, -1]$ under t_1 and t_2.

You should have found that both of the projective transformations t_1 and t_2 map the Points $[1, -1, 1]$, $[1, -2, 2]$ and $[-1, 2, -1]$ to the Points $[-2, 0, 1]$, $[0, 3, -2]$ and $[1, -2, 1]$, respectively. Notice, however, that t_1 and t_2 are not the same projective transformation, since their matrices are not multiples of each other. It follows that, unlike affine transformations, projective transformations are not uniquely determined by their effect on three (non-collinear) Points.

This raises the question as to whether it is possible to specify how many Points *are* required to determine a projective transformation. According to the Fundamental Theorem of Projective Geometry, the answer is four. In fact the theorem states that given any two sets of four Points, no three of which are collinear, there is a *unique* projective transformation that maps the Points in one set to the corresponding Points in the second set. Thus, in projective geometry a transformation is uniquely determined by its effect on a quadrilateral.



To understand why a triangle is insufficient to determine a projective transformation uniquely, consider what happens when we look for a projective transformation that maps the triangle of reference to three given non-collinear Points.

Recall that the Points [1, 0, 0], [0, 1, 0] and [0, 0, 1] are known as the *triangle of reference.*

Example 4 Find a projective transformation t that maps the Points [1, 0, 0], [0, 1, 0] and [0, 0, 1] to the non-collinear Points $[1, -1, 1]$, $[1, -2, 2]$ and $[-1, 2, -1]$, respectively.

Solution Let $\mathbf{A}$ be a matrix associated with t, and let the first column of $\mathbf{A}$ be $\begin{pmatrix} a \\ b \\ c \end{pmatrix}$. Then since

$$\begin{pmatrix} a & * & * \\ b & * & * \\ c & * & * \end{pmatrix}\begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix} = \begin{pmatrix} a \\ b \\ c \end{pmatrix} = \begin{pmatrix} 1 \\ -1 \\ 1 \end{pmatrix},$$

Here the asterisks * denote unspecified numbers.

it follows that we may take $\begin{pmatrix} 1 \\ -1 \\ 1 \end{pmatrix}$ as the first column of $\mathbf{A}$.

Similarly, since

$$\begin{pmatrix} * & d & * \\ * & e & * \\ * & f & * \end{pmatrix}\begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} = \begin{pmatrix} d \\ e \\ f \end{pmatrix} = \begin{pmatrix} 1 \\ -2 \\ 2 \end{pmatrix}$$

and

$$\begin{array}{cc} g & 0 \\ h & 0 \\ k & 1 \end{array} = \begin{array}{c} g \\ h \\ k \end{array} = \begin{array}{c} 1 \\ 2 \\ 1 \end{array},$$

it follows that a suitable transformation is given by $t : [\mathbf{x}] \quad [\mathbf{A}x]$ where

$$\mathbf{A} = \begin{array}{ccc} 1 & 1 & 1 \\ 1 & 2 & 2 \\ 1 & 2 & 1 \end{array}.$$

□

Notice that because the Points [1, 1, 1], [1, 2, 2] and [1, 2, 1] are not collinear it follows that the columns of **A** are linearly independent, so that **A** is invertible.

This example illustrates the fact that we can always find a projective transformation $t : [\mathbf{x}] \quad [\mathbf{Ax}]$ which maps the triangle of reference to three non-collinear Points simply by writing the homogeneous coordinates of the Points as the columns of **A**. Notice, however, that the transformation we obtain is not unique. Indeed, if the Points [1, 1, 1], [1, 2, 2] and [1, 2, 1] in Example 4 are rewritten in the form $[u, \ u, u]$, [, 2 , 2] and [w, 2w, w], for some non-zero real numbers u, , w, then the matrix becomes

$$\mathbf{A} = \begin{array}{ccc} u & & w \\ u & 2 & 2w \\ u & 2 & w \end{array}.$$

The corresponding transformation $t : [\mathbf{x}] \quad [\mathbf{Ax}]$ still maps the triangle of reference to the Points [1, 1, 1], [1, 2, 2] and [1, 2, 1], as required, but the effect that t has on the other Points of $\mathbb{RP}^2$ depends on the numbers u, v and w.

So if we wish to specify t uniquely we need to assign particular values to u, v and w. We can do this by specifying the effect that t has on a fourth Point [1, 1, 1].

Recall that the Point [1, 1, 1] is known as the *unit Point.*

Example 5 Find the projective transformation t which maps the Points [1, 0, 0], [0, 1, 0], [0, 0, 1] and [1, 1, 1] to the Points [1, 1, 1], [1, 2, 2], [1, 2, 1] and [0, 1, 2], respectively.

Solution If **A** is the matrix associated with t, then its columns must be multiples of the homogeneous coordinates [1, 1, 1], [1, 2, 2], [1, 2, 1]; that is,

$$\mathbf{A} = \begin{array}{ccc} u & & w \\ u & 2 & 2w \\ u & 2 & w \end{array}.$$

Also, to ensure that t maps [1, 1, 1] to [0, 1, 2] we must choose u, v and w so that

$$\begin{pmatrix} u & v & -w \\ -u & -2v & 2w \\ u & 2v & -w \end{pmatrix}\begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix} = \begin{pmatrix} 0 \\ 1 \\ 2 \end{pmatrix}.$$

We can do this by solving the equations

$$\begin{aligned} u + v - w &= 0, \\ -u - 2v + 2w &= 1, \\ u + 2v - w &= 2. \end{aligned}$$

Adding the second and third equations we obtain $w = 3$. If we then subtract the first equation from the third we obtain $v = 2$. Finally, if we substitute v and w into the first equation we obtain $u = 1$. The required projective transformation is therefore given by $t : [\mathbf{x}] \mapsto [\mathbf{Ax}]$, where

$$\mathbf{A} = \begin{pmatrix} 1 & 2 & -3 \\ -1 & -4 & 6 \\ 1 & 4 & -3 \end{pmatrix}.$$

□

The columns of **A** are still linearly independent because they are non-zero multiples of the linearly independent vectors $(1, -1, 1)$, $(1, -2, 2)$ and $(-1, 2, -1)$.

It is natural to ask whether the method used in this example can be adapted to find a projective transformation which maps the triangle of reference and unit Point to *any* four given Points. The answer is usually yes, but since collinearity is a projective property, and since no three of the Points [1, 0, 0], [0, 1, 0], [0, 0, 1], [1, 1, 1] are collinear, the method must fail if three of the four given Points lie on a Line. Provided we exclude this possibility, the answer is yes!

Strategy To find the projective transformation which maps

$[1, 0, 0]$ to $[a_1, a_2, a_3]$,
$[0, 1, 0]$ to $[b_1, b_2, b_3]$,
$[0, 0, 1]$ to $[c_1, c_2, c_3]$,
$[1, 1, 1]$ to $[d_1, d_2, d_3]$,

where no three of $[a_1, a_2, a_3], [b_1, b_2, b_3], [c_1, c_2, c_3], [d_1, d_2, d_3]$ are collinear:

1. Find u, v, w such that

$$\begin{pmatrix} a_1u & b_1v & c_1w \\ a_2u & b_2v & c_2w \\ a_3u & b_3v & c_3w \end{pmatrix}\begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix} = \begin{pmatrix} d_1 \\ d_2 \\ d_3 \end{pmatrix};$$

We explain why the method works in the Remark that follows the strategy.

2. write down the required projective transformation in the form $t : [\mathbf{x}]$ $[\mathbf{Ax}]$, where $\mathbf{A}$ is any non-zero real multiple of the matrix

$$\begin{matrix} a_1 u & b_1 v & c_1 w \\ a_2 u & b_2 v & c_2 w \\ a_3 u & b_3 v & c_3 w \end{matrix} .$$

The non-zero multiple can be used to clear fractions from the entries of the matrix **A**.

Remark

To see why this strategy always works, notice that we can rewrite the equation from Step 1 in the form

$$u \begin{matrix} a_1 \\ a_2 \\ a_3 \end{matrix} + v \begin{matrix} b_1 \\ b_2 \\ b_3 \end{matrix} + w \begin{matrix} c_1 \\ c_2 \\ c_3 \end{matrix} = \begin{matrix} d_1 \\ d_2 \\ d_3 \end{matrix} .$$

From this we can make the following observations.

(a) The equation in Step 1 must have a unique solution for u, v, w because the required values of u, v and w are simply the coordinates of (d_1, d_2, d_3) with respect to the basis of $\mathbb{R}^3$ formed from the three linearly independent vectors $(a_1, a_2, a_3), (b_1, b_2, b_3), (c_1, c_2, c_3)$.

(b) The values *of* u, v and w must all be non-zero, because otherwise three of the vectors $(a_1, a_2, a_3), (b_1, b_2, b_3), (c_1, c_2, c_3), (d_1, d_2, d_3)$ would be linearly dependent.

(c) Since the columns of $\mathbf{A}$ are non-zero, multiples of the linearly independent vectors $(a_1, a_2, a_3), (b_1, b_2, b_3), (c_1, c_2, c_3)$ it follows that $\mathbf{A}$ is invertible, and hence that t is a projective transformation.

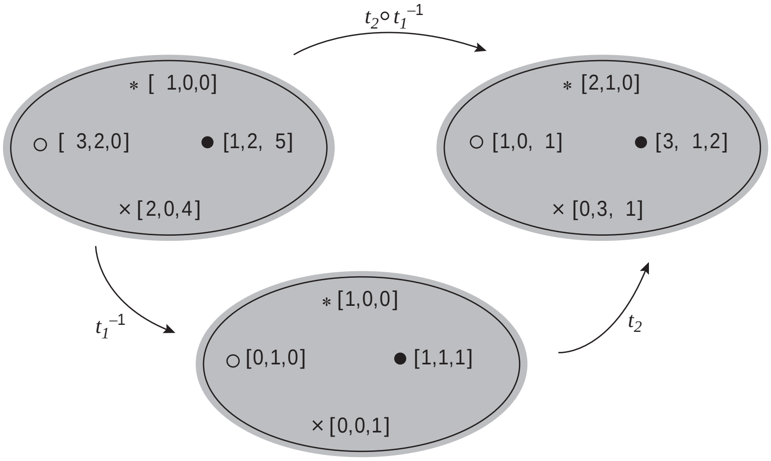
Since no three of the Points $[a_1, a_2, a_3]$, $[b_1, b_2, b_3]$, $[c_1, c_2, c_3]$, $[d_1, d_2, d_3]$ are collinear, it follows that *any three* of the vectors (a_1, a_2, a_3), (b_1, b_2, b_3), (c_1, c_2, c_3), (d_1, d_2, d_3) must be linearly independent.

There is no need to check whether any three of the four given Points are collinear because any failure of this condition will emerge in the process of applying the strategy. Indeed, if the equation in Step 1 fails to yield unique non-zero values for u, v and w, then it must be because three of the Points $(a_1, a_2, a_3), (b_1, b_2, b_3), (c_1, c_2, c_3), (d_1, d_2, d_3)$ lie on a Line.

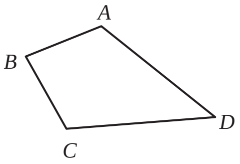
Problem 7 Use the above strategy to find the projective transformation which maps the Points [1, 0, 0], [0, 1, 0], [0, 0, 1] and [1, 1, 1] to the Points:

(a) [1, 0, 0], [3, 2, 0], [2, 0, 4] and [1, 2, 5], respectively;
(b) [1, 0, 0], [0, 0, 1], [0, 1, 0] and [3, 4, 5], respectively;
(c) [2, 1, 0], [1, 0, 1], [0, 3, 1] and [3, 1, 2], respectively.

Now consider the transformation t_1 in Problem 7(a). The inverse of this, $t_1{}^{1}$, is a projective transformation which maps the Points [1, 0, 0], [3, 2, 0], [2, 0, 4] and [1, 2, 5] back to the triangle of reference and unit Point. So if, after applying this inverse, we apply the projective transformation t_2 in Problem 7(c), then the overall effect of the composite $t_2 \circ t_1^{-1}$ is that of a projective transformation which sends the Points $[-1, 0, 0]$, $[-3, 2, 0]$, $[2, 0, 4]$ and $[1, 2, -5]$ directly to the Points $[2, 1, 0]$, $[1, 0, -1]$, $[0, 3, -1]$ and $[3, -1, 2]$, respectively.



In a similar way we can find a projective transformation which maps any set of four Points to any other set of four Points. The only constraint is that no three of the Points in either set can be collinear. In the following statement of the Fundamental Theorem we express this constraint by requiring that each of the four sets of Points lie at the vertices of some quadrilateral, where a *quadrilateral* is defined as follows. A *quadrilateral* is a set of four Points A, B, C and D (no three of which are collinear), together with the Lines AB, BC, CD and DA.

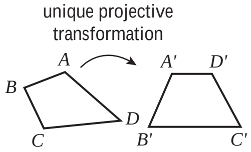


Theorem 3 The Fundamental Theorem of Projective Geometry
Let $ABCD$ and $A'B'C'D'$ be two quadrilaterals in $\mathbb{RP}^2$. Then:

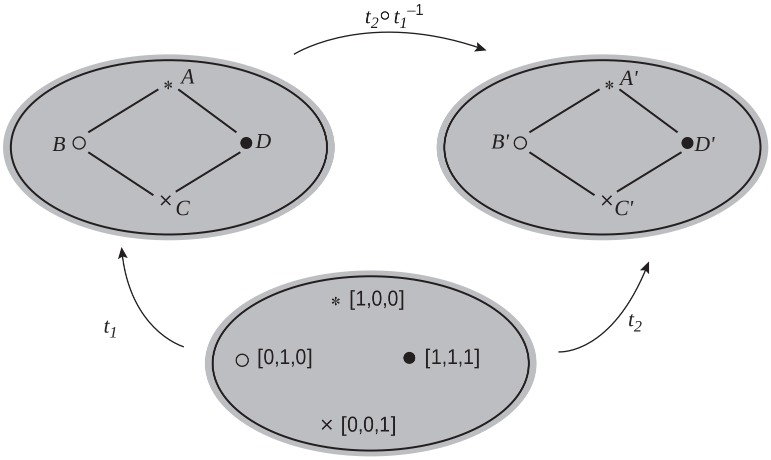
(a) there is a projective transformation t which maps

$$A \text{ to } A',\ B \text{ to } B',\ C \text{ to } C',\ D \text{ to } D';$$

(b) the projective transformation t is unique.



Proof According to the strategy above, there is a projective transformation t_1 which maps the Points $[1, 0, 0]$, $[0, 1, 0]$, $[0, 0, 1]$, $[1, 1, 1]$ to the Points A, B, C, D, respectively. Similarly, there is a projective transformation t_2 which maps the Points $[1, 0, 0]$, $[0, 1, 0]$, $[0, 0, 1]$, $[1, 1, 1]$ to the Points A', B', C', D', respectively.



(a) The composite $t = t_2 \circ t_1^{-1}$ is then a projective transformation which maps A to A', B to B', C to C', D to D'.

(b) To check uniqueness of t, we first check that the identity transformation is the only projective transformation which maps each of the Points [1, 0, 0], [0, 1, 0], [0, 0, 1], [1, 1, 1] to themselves. In fact any projective transformation with this property must have an associated matrix which is some non-zero multiple of the matrix

$$\begin{pmatrix} u & 0 & 0 \\ 0 & v & 0 \\ 0 & 0 & w \end{pmatrix}, \quad \text{where} \quad \begin{pmatrix} u & 0 & 0 \\ 0 & v & 0 \\ 0 & 0 & w \end{pmatrix} \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix} = \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix}.$$

Such a matrix must be (a non-zero multiple of) the identity matrix, and so the transformation must indeed be the identity.

This follows from the discussion leading to the strategy above.

Next suppose that t and t' are two projective transformations which satisfy the conditions of the theorem. Then the composites $t_2^{-1} \circ t \circ t_1$ and $t_2^{-1} \circ t' \circ t_1$ must both be projective transformations which map each of the Points [1, 0, 0], [0, 1, 0], [0, 0, 1], [1, 1, 1] to themselves. Since this implies that both composites are equal to the identity, we deduce that

$$t_2^{-1} \circ t \circ t_1 = t_2^{-1} \circ t' \circ t_1.$$

If we now compose both sides of this equation with t_2 on the left and with t_1^{-1} on the right, then we obtain $t = t'$, as required.

The Fundamental Theorem tells us that there is a projective transformation which maps any given quadrilateral onto any other given quadrilateral. So we have the following corollary.

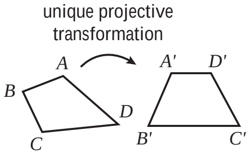
Corollary All quadrilaterals are projective-congruent.

By *projective-congruent* we mean that there is a projective transformation that maps any quadrilateral onto any other quadrilateral.

If we actually need to find the projective transformation which maps one given quadrilateral onto another given quadrilateral, we simply follow the strategy used to prove part (a) of the Fundamental Theorem.

Strategy To determine the projective transformation t which maps the vertices of the quadrilateral $ABCD$ to the corresponding vertices of the quadrilateral $A\ B\ C\ D$:

1. find the projective transformation t_1 which maps the triangle of reference and unit Point to the Points A, B, C, D, respectively;
2. find the projective transformation t_2 which maps the triangle of reference and unit Point to the Points $A\ , B\ , C\ , D$, respectively;
3. calculate $t = t_2 \quad t_1^{\ \ 1}$.



Example 6 Find the projective transformation t which maps the Points [1, 1, 2], [1, 2, 1], [5, 1, 2], [1, 0, 1] to the Points [1, 3, 2], [3, 7, 5], [2, 5, 4], [3, 8, 5], respectively.

Solution We follow the steps in the above strategy.

(a) Any matrix associated with the projective transformation t_1 which maps the Points [1, 0, 0], [0, 1, 0], [0, 0, 1], [1, 1, 1] to the Points [1, 1, 2], [1, 2, 1], [5, 1, 2], [1, 0, 1], respectively, must be a multiple of the matrix

$$\begin{matrix} u & v & 5w \\ u & 2v & w \\ 2u & v & 2w \end{matrix} \ , \quad \text{where} \quad \begin{matrix} u & v & 5w \\ u & 2v & w \\ 2u & v & 2w \end{matrix} \quad \begin{matrix} 1 \\ 1 \\ 1 \end{matrix} \ = \ \begin{matrix} 1 \\ 0 \\ 1 \end{matrix} \ .$$

Solving the equations

$$u + v + 5w = 1,$$
$$u \quad 2v \quad w = 0,$$
$$2u + v + 2w = 1,$$

we obtain $u = \frac{1}{2}, v = \quad \frac{1}{3}, w = \frac{1}{6}$. So a suitable choice of matrix for t_1 is

$$\begin{matrix} \frac{1}{2} & \frac{1}{3} & \frac{5}{6} \\ \frac{1}{2} & \frac{2}{3} & \frac{1}{6} \\ 1 & \frac{1}{3} & \frac{1}{3} \end{matrix} \ , \quad \text{or more simply } \mathbf{A}_1 = \begin{matrix} 3 & 2 & 5 \\ 3 & 4 & 1 \\ 6 & 2 & 2 \end{matrix} \ .$$

It is simpler to multiply the first matrix by 6 to obtain integer entries. This does not alter the projective transformation t_1 with which the matrix is associated.

(b) Any matrix associated with the projective transformation t_2 which maps the Points [1, 0, 0], [0, 1, 0], [0, 0, 1], [1, 1, 1] to the Points [1, 3, 2], [3, 7, 5], [2, 5, 4], [3, 8, 5], respectively, must be a multiple of the matrix

$$\begin{matrix} u & 3v & 2w \\ 3u & 7v & 5w \\ 2u & 5v & 4w \end{matrix} \ , \ \text{where} \quad \begin{matrix} u & 3v & 2w \\ 3u & 7v & 5w \\ 2u & 5v & 4w \end{matrix} \quad \begin{matrix} 1 \\ 1 \\ 1 \end{matrix} \ = \ \begin{matrix} 3 \\ 8 \\ 5 \end{matrix} \ .$$

Solving the equations

$$\begin{aligned} u \quad 3v + 2w &= \quad 3,\\ 3u + 7v \quad 5w &= 8,\\ 2u \quad 5v + 4w &= \quad 5, \end{aligned}$$

we obtain $u = 2, v = 1, w = 1$. So a suitable choice of matrix for t_2 is

$$\mathbf{A}_2 = \begin{matrix} 2 & 3 & 2\\ 6 & 7 & 5\\ 4 & 5 & 4 \end{matrix}.$$

(c) A matrix associated with the inverse, $t_1^{\ 1}$, of t_1 is $\mathbf{A}_1^{\ 1}$, which we can calculate to be

$$\mathbf{A}_1^{\ 1} = \begin{matrix} \frac{1}{12} & \frac{1}{12} & \frac{1}{4}\\ 0 & \frac{1}{3} & \frac{1}{6}\\ \frac{1}{4} & \frac{1}{12} & \frac{1}{12} \end{matrix};$$

then a simpler matrix associated with $t_1^{\ 1}$ is

$$\mathbf{B} = \begin{matrix} 1 & 1 & 3\\ 0 & 4 & 2\\ 3 & 1 & 1 \end{matrix}.$$

The required projective transformation is therefore $t : [\mathbf{x}] \quad [\mathbf{A}x]$, where

$$\begin{aligned} \mathbf{A} = \mathbf{A}_2\mathbf{B} &= \begin{matrix} 2 & 3 & 2\\ 6 & 7 & 5\\ 4 & 5 & 4 \end{matrix} \quad \begin{matrix} 1 & 1 & 3\\ 0 & 4 & 2\\ 3 & 1 & 1 \end{matrix}\\ &= \begin{matrix} 8 & 12 & 14\\ 21 & 29 & 37\\ 16 & 20 & 26 \end{matrix}. \end{aligned}$$

□

Problem 8 Find the projective transformation t that maps the Points [1, 0, 0], [3, 2, 0], [2, 0, 4], [1, 2, 5] to the Points [2, 1, 0], [1, 0, 1], [0, 3, 1], [3, 1, 2], respectively.

Problem 9 Find the projective transformation t that maps the Points [1, 0, 3], [1, 1, 2], [3, 3, 5], [6, 4, 13] to the Points [3, 5, 3], [$\frac{1}{2}$, 1, 0], [3, 5, 6], [8, 13, 12], respectively.

3.3.4 Geometrical Interpretation of Projective Transformations

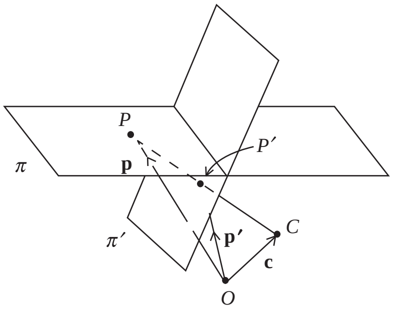
You may omit this subsection at a first reading, as it is quite hard going.

In this subsection we discuss the relationship between projective transformations and the perspectivities introduced in Section 3.1.

Starting from the geometric definition of perspective in Subsection 3.1.1, we will define the term *perspective transformation*, show how a perspective transformation may be interpreted as a projective transformation, and finally prove that any projective transformation can be expressed as the composite of at most three perspective transformations.

Recall that a *projective transformation* of $\mathbb{R}P^2$ is a map $[\mathbf{x}] \quad [\mathbf{Ax}]$, where $\mathbf{A}$ is an invertible 3×3 matrix.

So, let and be two embedding planes in $\mathbb{R}^3$ that do not pass through the origin O in $\mathbb{R}^3$, and let C $(= \; O)$ be another point in $\mathbb{R}^3$ such that OC is not parallel to either or . Let C have position vector $\mathbf{c}$ (based at O). Also, let denote an arbitrary perspectivity from the point C that maps the plane to the plane .



Note that O, C, P and P are coplanar.

Now, the perspectivity will map any point P (with position vector $\mathbf{p}$) in onto some point P (with position vector $\mathbf{p}$) in , so long as the vector $\mathbf{p} \quad \mathbf{c}$ is not parallel to the plane . We then define the perspective transformation associated with to be the mapping of $\mathbb{R}^3$ to itself that maps the line $[\mathbf{p} \quad \mathbf{c}]$ onto the line $[\mathbf{p} \quad \mathbf{c}]$. But since C, P and P are collinear, it follows that the vectors $\mathbf{p} \quad \mathbf{c}$ and $\mathbf{p} \quad \mathbf{c}$ must be parallel (equivalently, that $[\mathbf{p} \quad \mathbf{c}] = [\mathbf{p} \quad \mathbf{c}]$); hence there is some real number t such that

$$\mathbf{p} \quad \mathbf{c} = t(\mathbf{p} \quad \mathbf{c}).$$

Recall that a line through the origin in $\mathbb{R}^2$ is a 1-dimensional vector space.

The value of t will depend on the particular point P under discussion.

We can then rewrite this formula in the form

$$\mathbf{p} \; = t(\mathbf{p} \quad \mathbf{c}) + \mathbf{c},$$

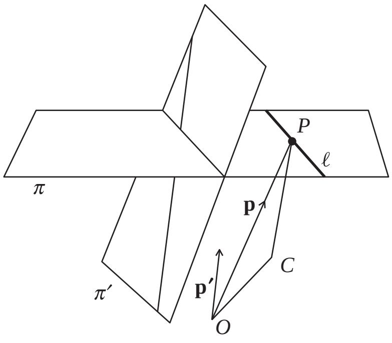
or

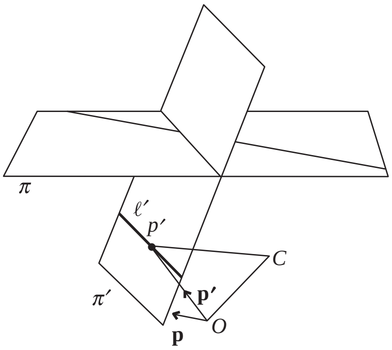
$$\mathbf{p} \; = t\mathbf{p} + (1 \quad t)\mathbf{c},$$

so that

$$[\mathbf{p}] \qquad [t\mathbf{p} + (1 \quad t)\mathbf{c}].$$

In this way, the perspectivity gives a one-one mapping from onto , except that it is not defined on the line in where cuts the plane through C parallel to ; also, there are no points of that map onto points of on the line where cuts the plane through C parallel to . We use the fact that the ideal Points for a plane correspond to the directions of lines in the plane, rather than actual points in the plane, to extend our definition of the map.





So, first, let P be a point of that lies on the line ; then the points O, C, P are not collinear, since OC is not parallel to the plane . Denote the position vector OP by $\mathbf{p}$. Let the plane through O, C and P meet the plane in a line, and let $\mathbf{p}$ be a position vector based at O that is parallel to this line. Then we specify that our (extended) map maps the line $[\mathbf{p}]$ through O onto the line $[\mathbf{p}\ ]$ through O.

Similarly, let P be a point of that lies on the line ; then the points O, C, P are not collinear, since OC is not parallel to the plane . Denote the position vector OP by $\mathbf{p}$. Let the plane through O, C and P meet the plane in a line, and let $\mathbf{p}$ be a position vector based at O that is parallel to this line. Then we specify that our (further extended) map maps the line $[\mathbf{p}]$ through O onto the line $[\mathbf{p}\ ]$ through O.

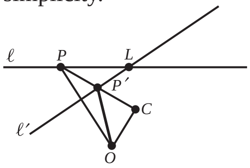
Finally, we specify that the extended map maps the line through O that is parallel to the line of intersection of and onto itself.

In this way, we have constructed a transformation that is a one-one mapping of $\{$the ideal Points for $\}$ onto the ideal Points for associated in a natural way with the given perspectivity , and we call it the associated **perspective transformation**. This maps the family of Euclidean lines through O onto itself, in other words RP^2 onto itself.

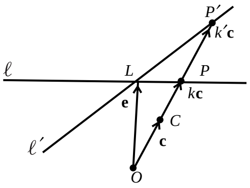
We now explain why we can think of this perspective transformation as a projective transformation.

First, we consider a perspectivity in R^2 as this will prove useful later in our discussion. So, let and be two lines in R^2 that do not pass through the origin O in R^2, let L be the common point of the two lines, and let $C(= O)$ be another point in R^2 such that OC is not parallel to either or . Consider any perspectivity , with centre some point C, say, that maps onto .

In our discussion we shall omit discussion of the exceptional points , for simplicity.



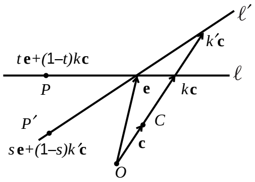
We are interested in the map that sends lines through O to lines through O that is obtained from as follows. Let map the point P on onto the point P on . Then we define $(OP) = OP$.



It is clear that $(OL) = OL$, because L is fixed by .

It is also clear that $(OC) = OC$, because if the line OC meets at P and the line at P then O, C, P and P are collinear and so $(OC) = OC$.

We therefore choose to take as basis vectors in R^2 the vector $\mathbf{e} = OL$ and the vector $\mathbf{c} = OC$.



We now find the effect of the map on a line through the origin O. We shall suppose that the line OC meets the line at the point with position vector $k\mathbf{c}$ and the line at the point with position vector $k\ \mathbf{c}$. Any point P on the line then has position vector $t\mathbf{e} + (1\quad t)k\mathbf{c}$, for some real number t, and any point P on the line has position vector $s\mathbf{e} + (1\quad s)k\ \mathbf{c}$, for some real number s.

Next, the line OP consists of the points with coordinates $u(\mathbf{e} + m\mathbf{c}) = u\mathbf{e} + mu\mathbf{c}$ for a fixed value of m and varying values of u. This gives two (equivalent) expressions for the position of the point P, namely $t\mathbf{e}+(1\quad t)k\mathbf{c}$ and $u\mathbf{e}+mu\mathbf{c}$. It follows that we must have

$$u = t \quad \text{and} \quad mu = (1\quad t)k.$$

Dividing the second equation by the first, we get

$$m = \frac{1\quad t}{t}k$$

so that

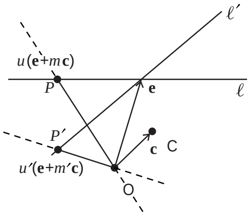
$$tm = k\quad kt,$$

which yields the formula

$$t = \frac{k}{m + k}.$$

Similarly, the line OP consisting of points $u\ (\mathbf{e} + m\ \mathbf{c}) = u\ \mathbf{e} + m\ u\ \mathbf{c}$, for a fixed value of m and varying values of u , meets the line at the point P where

$$s = \frac{k}{m\ + k}.$$



Now, we have $(OP) = OP$ if and only if the points C, P and P are collinear; that is, if and only if there is a real number r such that

$$r(t\mathbf{e} + (1\quad t)k\mathbf{c}\quad \mathbf{c}) = s\mathbf{e} + (1\quad s)k\ \mathbf{c}\quad \mathbf{c}.$$

This is the case if and only if

$$rt = s \quad \text{and} \quad r((1\quad t)k\quad 1) = (1\quad s)k\quad 1.$$

We can eliminate r by dividing the second equation by the first equation, so obtaining

$$\frac{(1\quad t)k\quad 1}{t} = \frac{(1\quad s)k\quad 1}{s}.$$

Then, if we substitute $t = \frac{k}{m+k}$ and $s = \frac{k}{m\ +k}$ into this equation, after some manipulation we obtain the remarkable result that

$$m\ = m\frac{(k\quad 1)k}{(k\quad 1)k}.$$

It follows that, in terms of the basis elements **e** and **c**, the map of the family of lines through O to itself given by

$$\begin{matrix} 1 \\ m \end{matrix} \qquad \begin{matrix} 1 \\ m \end{matrix}$$

can be represented by the matrix

$$\begin{matrix} 1 & 0 \\ 0 & \frac{(k \quad 1)k}{(k \quad 1)k} \end{matrix} .$$

For convenience, we write this matrix in the form

$$\begin{matrix} 1 & 0 \\ 0 & r \end{matrix} ,$$

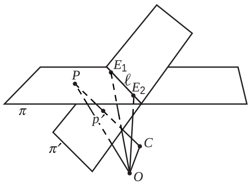
where r is a fixed number that depends only on the geometry of the two lines and and on our choice of the point C. Furthermore, $r = 0$ since $k = 1$ (for $k = 1$ implies that C lies on) and $k = 0$ (for $k = 0$ implies that O lies on).

Now we consider the situation in R^3, in relation to RP^2. Consider an arbitrary perspectivity , with centre some point C, say, that maps a plane onto a plane , with neither O nor C lying on or . As before, we shall suppose that the line OC meets the plane at a point with position vector $k\mathbf{c}$ and the plane at a point with position vector $k\ \mathbf{c}$.

Once again, we are interested in the map that sends lines (in R^3) through O to lines through O that is obtained from as follows. Let map a point P in to a point P in . Then we define $(OP) = OP$.

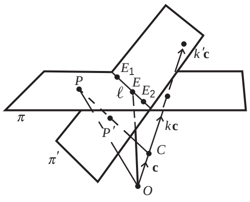
Let E_1 and E_2 be any two points on the common line of the two planes. Then, clearly, $(OE_1) = OE_1$ and $(OE_2) = OE_2$ because every point of is fixed by .

It is also clear that $(OC) = OC$, because if the line OC meets the plane at Q and the plane at Q , then O, C, Q and Q are collinear, and so $(OC) = OC$.



We therefore now take as basis vectors in R^3 the vectors $\mathbf{e}_1 = OE_1$, $\mathbf{e}_2 = OE_2$, and $\mathbf{c} = OC$.

We now find the effect of on a line in R^3 through the origin O. We can simplify our task by observing that the lines OC, OP and OP all lie in a plane, say; let this plane meet the line common to the given planes and at a point E. We then define $\mathbf{e} = OE$.



We can now apply our earlier discussion of the planar case to the restriction of the mapping to the plane . If we denote the lines OP and OP by the parametrizations

$$OP = u(\mathbf{e} + m\mathbf{c}) = u\mathbf{e} + um\mathbf{c}, \quad \text{where } m \text{ is fixed and } u \text{ varies,}$$

$$OP \ = u\ (\mathbf{e} + m\ \mathbf{c}) = u\ \mathbf{e} + u\ m\ \mathbf{c}, \quad \text{where } m \text{ is fixed and } u \text{ varies,}$$

it follows from our earlier discussion that m can be expressed in the form rm, where r is a fixed number that depends only on the geometry of the two planes and and on our choice of the point C. Hence we can rewrite the parametrization of OP as

$$OP = u (\mathbf{e} + rm\mathbf{c}) = u \mathbf{e} + u rm\mathbf{c}, \quad \text{where } r, m \text{ are fixed and } u \text{ varies.}$$

Next, we can express the position vector $\mathbf{e}$ of the point E in the form

$$\mathbf{e} = t\mathbf{e}_1 + (1 \quad t)\mathbf{e}_2, \quad \text{for some number } t.$$

Then we have that the mapping maps the line

$$OP = u(t\mathbf{e}_1 + (1 \quad t)\mathbf{e}_2 + m\mathbf{c}) = ut\mathbf{e}_1 + u(1 \quad t)\mathbf{e}_2 + um\mathbf{c}$$

onto the line

$$OP = u (t\mathbf{e}_1 + (1 \quad t)\mathbf{e}_2 + rm\mathbf{c}) = u t\mathbf{e}_1 + u (1 \quad t)\mathbf{e}_2 + u rm\mathbf{c}.$$

It follows analogously to the two-dimensional situation that, in terms of the basis elements $\mathbf{e}_1, \mathbf{e}_2, \mathbf{c}$, the mapping of the family of lines in R^3 to itself can be represented by the matrix

$$\begin{matrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & r \end{matrix},$$

Notice that this maps the line represented by the points $[t, 1 \quad t, 0]$ to itself pointwise, as it should.

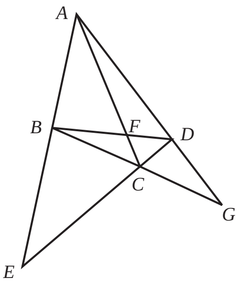
where the (non-zero) constant r depends only on the position of the planes and . Since this is an invertible 3 × 3 matrix, this is our required description of the perspective transformation as a projective transformation.

We now go the other way round, and obtain a projective transformation as a sequence of three perspective transformations. We have a lot of freedom, because we can choose the centres of perspectivities and the planes.

Suppose we are given a projective transformation and two embedding planes and . Let $[\mathbf{a}], [\mathbf{b}], [\mathbf{c}], [\mathbf{d}]$ be any four non-collinear Points, and $[\mathbf{a}], [\mathbf{b}], [\mathbf{c}], [\mathbf{d}]$ be any other four non-collinear Points; we can represent these Points by (Euclidean) points A, B, C, D in and A , B , C , D in , respectively.

We will use in our discussion the existence and uniqueness parts of the Fundamental Theorem of Projective Geometry: namely, that there is one and only one projective transformation mapping four non-collinear Points to any other four non-collinear Points. This means that if we can find a composite of three perspective transformations that maps $[\mathbf{a}], [\mathbf{b}], [\mathbf{c}], [\mathbf{d}]$ to $[\mathbf{a}], [\mathbf{b}], [\mathbf{c}], [\mathbf{d}]$, respectively, then this composite must be a projective transformation (by the existence part) and it must equal the given projective transformation (by the uniqueness part).

Subsection 3.3.3, Theorem 3

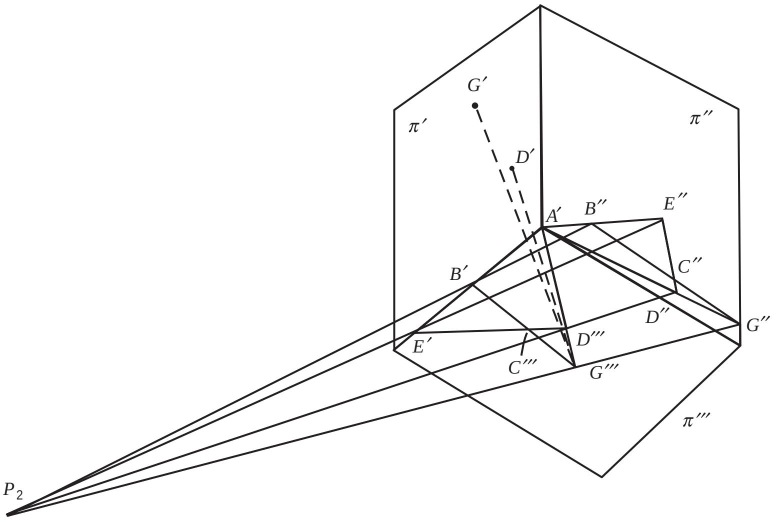


We now exhibit a sequence of three perspectivities the composite of which maps A, B, C, D in to A , B , C , D in . In our discussion it is convenient to let AB and CD meet at E, AC and BD meet at F, and AD and BC meet at G, with analogous definitions of E , F and G . (You may find the figures below helpful to follow through the argument; though, for simplicity, we have omitted the initial plane and the points F , F and F .)

1. The first perspectivity is from the plane to a plane that passes through A . The centre of this perspectivity is an arbitrary point P_1 on the line AA (if $A = A$, then P_1 can be chosen to lie anywhere not on or). This perspectivity maps A to A and B, C, D, E, F, G to B , C , D , E , F , G , say, respectively. We can assume, by suitably varying , that $B B$ and $E E$ are not parallel.

A A

B B , C C ,
D D , E E ,
F F , G G



2. Now, by the definition of E the points A , B , E lie on a line through A , and since the points A, B, E are collinear the points A , B , E lie on a line through A ; so these five points lie in a plane, and because the lines $B B$ and $E E$ are not parallel they meet in a point, P_2 say. We then pick a plane through the line $A B E$ and map the plane onto by the perspectivity with centre P_2. This sends A , B , E to A , B , E , respectively, and the points C , D , F , G to, say, C , D , F , G , respectively. As before, we can assume that $D D$ and $G G$ are not parallel.

A fixed;
B B , E E

C C , D D ,
F F , G G

3. Now, since A, D, G are collinear, the points A , D , G lie on a line through A and the points A , D , G lie on a line through A , so these five points lie in a plane; and because the lines $D D$ and $G G$ are not parallel they meet in a point, P_3 say. We then map the plane onto the plane by the perspectivity with centre P_3. This map sends A , B , D , E , G to A , B , D , E , G , respectively.

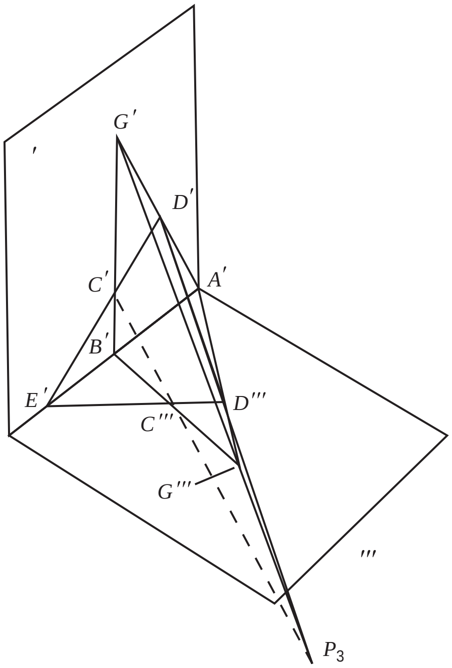
   This third perspectivity sends the line $B G$ to the line $B G$ and the line $D E$ to the line $D E$, so it maps the point C to the point C .

Refer here to the figure below.

A , B , E fixed

D D , G G

Thus the composite of these three perspectivities maps the points A, B, C, D in to A , B , C , D in , as required.



Theorem 4 Perspectivity Theorem
Every projective transformation can be expressed as the composite of three perspective transformations.

3.4 Using the Fundamental Theorem of Projective Geometry

In Section 3.2 we described how an embedding plane can be used to represent projective space $\mathbb{R}P^2$. The Points of $\mathbb{R}P^2$ are represented by Euclidean points in and the Lines of $\mathbb{R}P^2$ are represented by Euclidean lines in .

In general, any Euclidean figure in an embedding plane corresponds to a projective figure in $\mathbb{R}P^2$, and visa versa. This correspondence enables us to compare Euclidean theorems about a figure in an embedding plane with projective theorems about the corresponding projective figure. Provided that the theorems are concerned exclusively with projective properties, such as collinearity and incidence, then a Euclidean theorem will hold if and only if the corresponding projective theorem holds.

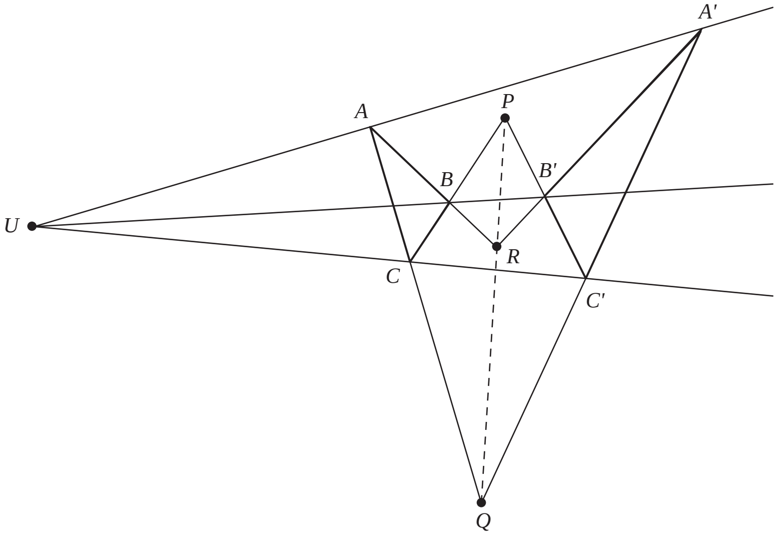
The Euclidean figure may have some ideal Points attached to it.

3.4.1 Desargues Theorem and Pappus Theorem

The advantage of interpreting a Euclidean theorem as a projective theorem in this way is that we can often obtain a much simpler proof of the theorem than would be possible using Euclidean geometry directly. We illustrate this by using projective geometry to prove the theorem of Desargues.

We introduced Desargues Theorem in Subsection 3.1.3.

Theorem 1 Desargues' Theorem
Let ABC and $A\ B\ C$ be triangles in $\mathbb{R}^2$ such that the lines AA , BB and CC meet at a point U. Let BC and $B\ C$ meet at P, CA and $C\ A$ meet at Q, and AB and $A\ B$ meet at R. Then P, Q and R are collinear.



Proof Because this theorem is concerned exclusively with the projective properties of collinearity and incidence we can interpret it as a projective theorem in $\mathbb{RP}^2$. Moreover, by the Fundamental Theorem of Projective Geometry we know that any configuration of the theorem is projective-congruent to a configuration of the theorem in which $A = [1, 0, 0]$, $B = [0, 1, 0]$, $C = [0, 0, 1]$ and $U = [1, 1, 1]$. If we can prove the theorem in this special case then we can use the fact that projective-congruence preserves projective properties to deduce that the theorem holds in general.

To prove the special case we use the algebraic techniques described in Section 3.2. First observe that the Line AU passes through the Points [1, 0, 0] and [1, 1, 1], and therefore has equation $y = z$. Since A is a Point on AU, it must have homogeneous coordinates of the form $[a, b, b]$, for some real numbers a and b. Now, $b = 0$, since $A = A$; so we may write the homogeneous coordinates of A in the form $[p, 1, 1]$ (where $p = a/b$).

For $[a, 0, 0] = [1, 0, 0]$.

Similarly, the homogeneous coordinates of the Points B and C may be written in the form $[1, q, 1]$ and $[1, 1, r]$, respectively, for some real numbers q and r.

We omit the details of the calculations.

We now find the Point P where BC and $B\ C$ intersect. The Line BC has equation $x = 0$. Since the Line $B\ C$ passes through the Points $B = [1, q, 1]$ and $C = [1, 1, r]$, it must have equation

$$\begin{matrix} x & y & z \\ 1 & q & 1 \\ 1 & 1 & r \end{matrix} = 0,$$

which we may rewrite in the form

$$(qr - 1)x - (r - 1)y + (1 - q)z = 0.$$

It follows that at the Point P of intersection of the Lines BC and $B'C'$ we must have $x = 0$ and $(r - 1)y = (1 - q)z$, so that P has homogeneous coordinates $[0, 1 - q, r - 1]$.

Similarly, the Points Q and R have homogeneous coordinates $[1 - p, 0, r - 1]$ and $[1 - p, q - 1, 0]$, respectively.

We omit the details of the calculations.

Now, the Points P, Q and R are collinear if

$$\begin{vmatrix} 0 & 1-q & r-1 \\ 1-p & 0 & r-1 \\ 1-p & q-1 & 0 \end{vmatrix} = 0.$$

But

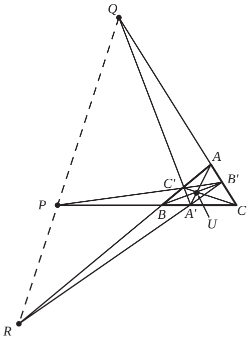
$$\begin{aligned} &\begin{vmatrix} 0 & 1-q & r-1 \\ 1-p & 0 & r-1 \\ 1-p & q-1 & 0 \end{vmatrix} \\ &= -(1-q)\begin{vmatrix} 1-p & r-1 \\ 1-p & 0 \end{vmatrix} + (r-1)\begin{vmatrix} 1-p & 0 \\ 1-p & q-1 \end{vmatrix} \\ &= -(1-q)(1-p)(1-r) + (r-1)(1-p)(q-1) \\ &= 0. \end{aligned}$$

It follows that P, Q and R are collinear, as asserted. The general result now holds, by projective-congruence.

When using the Fundamental Theorem to simplify proofs of results in projective geometry, we do not usually refer to projective-congruence. Instead, *so long as the properties involved are projective properties*, we content ourselves with an initial remark of the type: ‘By the Fundamental Theorem of Projective Geometry, we may choose the four Points…, no three of which are collinear, to be the triangle of reference and the unit Point; that is, to have homogeneous coordinates [1, 0, 0], [0, 1, 0], [0, 0, 1] and [1, 1, 1], respectively’.

Problem 1 Let $\triangle ABC$ be a triangle in $\mathbb{R}^2$, and let U be any point of $\mathbb{R}^2$ that is not collinear with any two of the points A, B and C. Let the lines AU, BU and CU meet the lines BC, CA and AB at the points A', B' and C', respectively. Next, let the lines BC and $B'C'$ meet at P, AC and $A'C'$ meet at Q, and AB and $A'B'$ meet at R. Prove that P, Q and R are collinear.

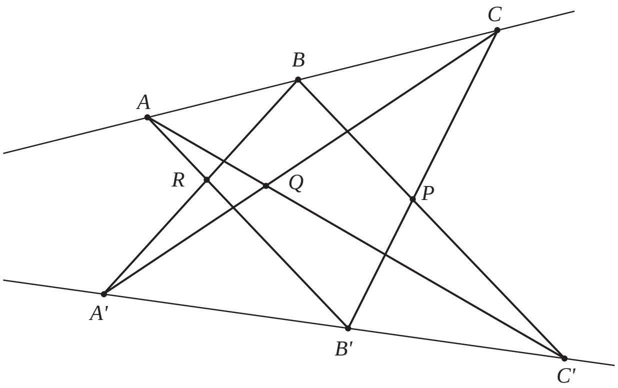
Hint: Let A, B, C be the vertices of the triangle of reference, and let U be the unit Point. Then determine the homogeneous coordinates of the Points A', B' and C'.



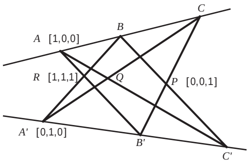
Next we use the Fundamental Theorem of Projective Geometry to prove Pappus Theorem.

Theorem 2 Pappus’ Theorem
Let A, B and C be three points on a line in $\mathbb{R}^2$, and let A , B and C be three points on another line. Let BC and $B C$ meet at P, CA and $C A$ meet at Q, and AB and $A B$ meet at R. Then P, Q, R are collinear.

This theorem is named after Pappus, a Greek mathematician who discovered it in the 3rd century AD.



Proof We interpret the theorem as a projective theorem, so: by the Fundamental Theorem of Projective Geometry we may choose the four Points A, A , P, R, no three of which are collinear, to be the triangle of reference and the unit Point; that is, to have homogeneous coordinates [1, 0, 0], [0, 1, 0], [0, 0, 1] and [1, 1, 1], respectively.



First observe that the Line AR passes through the Points [1, 0, 0] and [1, 1, 1], and must therefore have equation $y = z$. Since B is a Point on AR, it must have homogeneous coordinates of the form $[a, b, b]$ for some real numbers a and b. Now, $b = 0$ since $A = B$, so we may write the homogeneous coordinates of B in the form $[r, 1, 1]$ (where $r = a/b$).

Similarly, the Point B lies on the Line $x = z$ through the Points $A = [0, 1, 0]$ and $R = [1, 1, 1]$, so it must have homogeneous coordinates of the form $[1, s, 1]$.

Next we find the Point C where the Line AB intersects the Line $B P$. Since the Line AB passes through the Points $A = [1, 0, 0]$ and $B = [1, s, 1]$, it must have equation $y = sz$. Also since the Line $B P$ passes through the Points $B = [r, 1, 1]$ and $P = [0, 0, 1]$ it must have equation $x = ry$. At the Point C where AB meets $B P$ we have $y = sz$ and $x = ry$, so $C = [rs, s, 1]$.

Similarly, C is the point where the Line BP intersects the Line $A B$. Since $B = [1, s, 1]$ and $P = [0, 0, 1]$, BP has equation $y = sx$; and, since $A = [0, 1, 0]$ and $B = [r, 1, 1]$, $A B$ has equation $x = rz$. It follows that $C = [r, rs, 1]$.

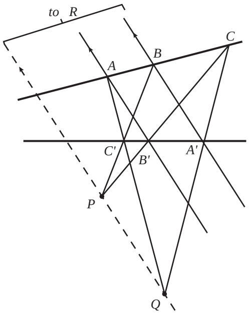
Finally we find the point Q where AC intersects $A C$. Since the Line AC passes through the Points $A = [1, 0, 0]$ and $C = [r, rs, 1]$ it must have equation $y = rsz$. Also the Line $A C$ passes through the Points $A = [0, 1, 0]$ and $C = [rs, s, 1]$ so it must have equation $x = rsz$. At the Point Q where AC intersects A C we have $y = rsz$ and $x = rsz$, so $Q = [rs, rs, 1]$.

To complete the proof we simply observe that the Points $R = [1, 1, 1]$, $Q = [rs, rs, 1]$ and $P = [0, 0, 1]$ all lie on the Line $x = y$. It follows that P, Q and R are collinear.

A fortunate choice of Points for the triangle of reference and unit Point meant that we did not have to use the determinant criterion for collinearity at the final stage of the argument.

Although we can sometimes simplify the proof of a Euclidean theorem by using projective geometry, there is another more subtle reason for interpreting a Euclidean theorem as a projective theorem. By doing so we can often avoid having to make special provision for exceptional cases, such as when two lines are parallel. In projective geometry, Lines which correspond to a pair of parallel lines in an embedding plane actually meet and are therefore no different to any other Lines.

As an example, consider the diagram in the margin. This illustrates the situation that occurs in Pappus Theorem when the Point of intersection R of $A B$ and AB is an ideal Point for the embedding plane. The above proof of Pappus Theorem is able to cope with this situation because it uses arguments from $\mathbb{RP}^2$! Our interpretation of the theorem on an embedding plane in this situation is that the Points P and Q must be collinear with the ideal Point R at which $A B$ and AB meet. That is, PQ must be parallel to both $A B$ and AB .

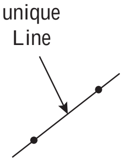


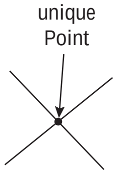
Problem 2 Give a Euclidean interpretation of Desargues Theorem on an embedding plane in the case where Q is an ideal Point for .

3.4.2 Duality

Recall that two key projective properties that we have met so far have a certain symmetry between them.

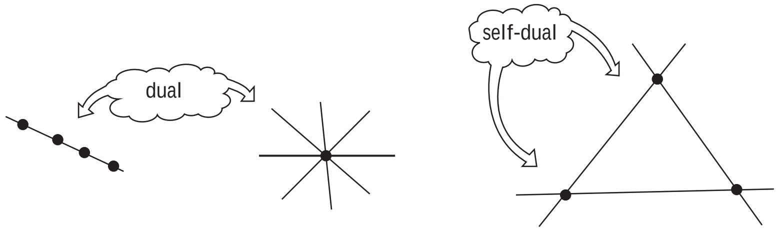
Collinearity Property	Incidence Property
Any two distinct *Points* lie on a unique *Line.*	Any two distinct *Lines* meet in a unique *Point.*



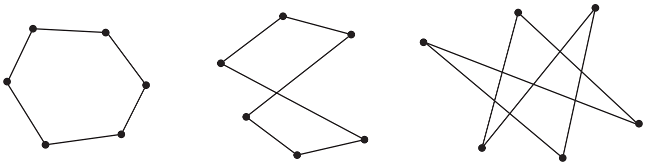


We can obtain one property from the other simply by interchanging the words Point and Line , and making whatever other changes are needed to ensure that the sentence makes sense. We say that this interchanging process *dualizes* one statement into the other, and that each statement is the *dual* of the other.

For example, a family of Points on a Line becomes a family of Lines through a Point under dualization. Similarly, a triangle or a family of three non-collinear Points and the three Lines joining them dualizes to a family of three non-concurrent Lines and the three Points where they meet , which is again a triangle. Since a triangle is thus dual to a triangle, we say that triangles are *self-dual* figures.



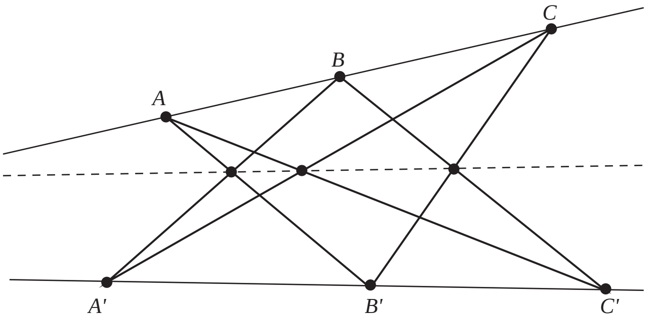
The dualization process is particularly interesting when applied to theorems. We shall illustrate this in the context of Pappus' Theorem. In order to do this, it is helpful to rephrase Pappus' Theorem using the term *hexagon.* As you would expect, a **hexagon** in $\mathbb{RP}^2$ consists of six Points joined by six Lines. The figure below illustrates (Euclidean) hexagons in an embedding plane; the corresponding hexagons in $\mathbb{RP}^2$ are the corresponding six Points and six Lines—that we model as six lines and six planes in $\mathbb{R}^3$.



We can now rephrase Pappus' Theorem in the following form.

Theorem 3 Pappus' Theorem (rephrased)
Let the vertices A, B', C, A', B and C' of a hexagon lie alternately on two different Lines. Then the Points of intersection of opposite sides $B'C$ and BC', CA' and $C'A$, AB' and $A'B$, are collinear.

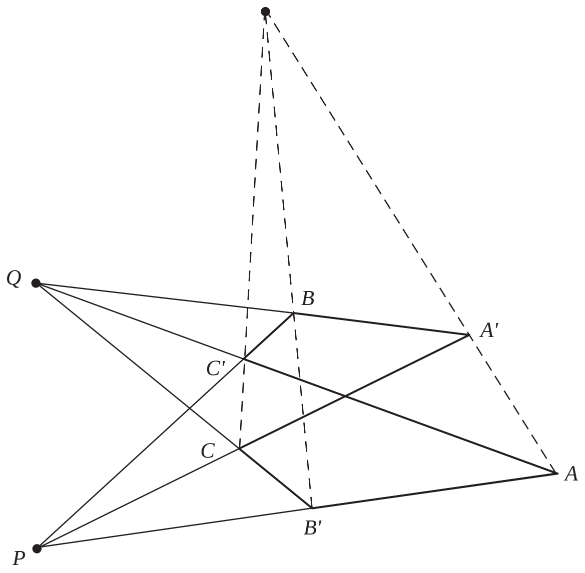
You should compare this formulation with that in Subsection 3.4.1.



If we dualize this theorem, we obtain the following theorem.

Theorem 4 Brianchon's Theorem
Let the sides AB', $B'C$, CA', $A'B$, BC', $C'A$ of a hexagon pass alternately through two (different) Points P and Q in $\mathbb{RP}^2$. Then the Lines joining opposite vertices A and A′, B and B', C and C', are concurrent.

Charles J. Brianchon (1785–1864) was one of many distinguished French geometers who studied under Gaspard Monge (1746–1818).



Problem 3 Prove Brianchon's Theorem.

Hint: Let P, C, Q, C be the Points [1, 0, 0], [0, 1, 0], [0, 0, 1], [1, 1, 1], respectively.

It turns out that the dual of any true statement concerning Points, Lines and their projective properties remains true after dualization; that is, if we dualize any theorem in projective geometry, then the statement that we obtain is itself a theorem.

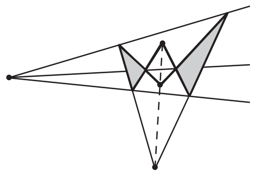
We do not prove this assertion, as it would take us beyond the scope of this book.

Problem 4 Earlier you saw that three Points $[a, b, c]$, $[d, e, f]$, $[g, h, k]$ are collinear if and only if $\begin{vmatrix} a & b & c \\ d & e & f \\ g & h & k \end{vmatrix} = 0$. Write down the dual result of this statement.

Subsection 3.2.2, Strategy

We end this subsection by forming the dual of Desargues' Theorem, as follows.

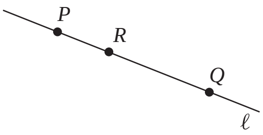
Desargues' Theorem	Dual Theorem
Let two *triangles* be such that the *Lines* joining corresponding *vertices* meet at a *Point*. Then the *Points* of intersection of the corresponding *sides* of the two *triangles* are *collinear*.	Let two *triangles* be such that the *Points* through which corresponding *sides* pass are *collinear*. Then the *Lines* through the corresponding *vertices* of the two *triangles* are *concurrent*.



Note that the dual theorem is simply the converse result for Desargues' Theorem! Thus the Principle of Duality enables us to deduce that the converse of Desargues' Theorem holds.

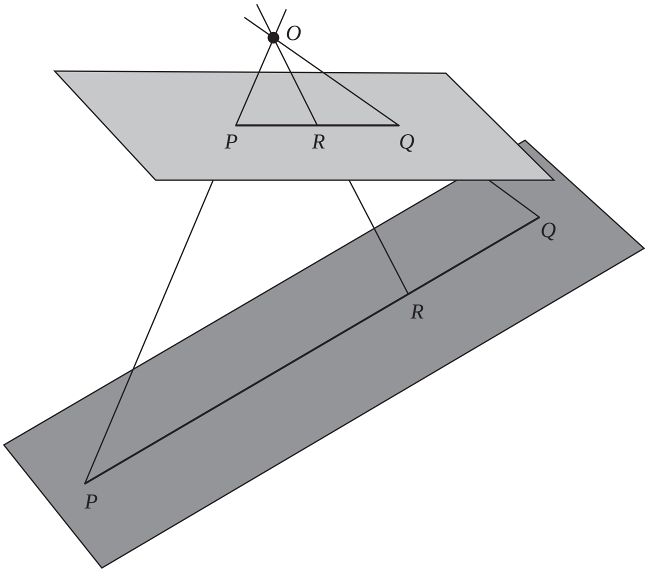
3.5 Cross-Ratio

3.5.1 Another Projective Property

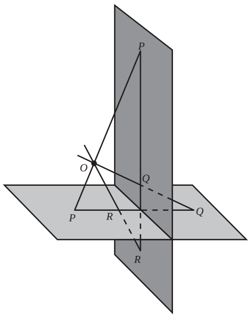


Earlier, in Subsection 2.2.1, we noted that *ratio of lengths along a line* is an affine property. Thus, in affine geometry, if we are given two points P and Q on a line , then we can locate the position of a third point R along by specifying the ratio $PR : RQ$. In particular, it is possible to talk about the point midway between P and Q.

In projective geometry it is meaningless to talk about the Point midway between two other Points. In one embedding plane a Point R may appear to be midway between the Points P and Q, whereas in another embedding plane the ratio $PR : RQ$ may be very different.



This ambiguity arises from the fact that perspectivities do not preserve the ratio of lengths along a line, so: *ratio of lengths along a line* is not a projective property.



In some embedding planes, such as the plane illustrated in the margin, the Point R does not even appear to lie between P and Q, so *betweenness* is not a projective property either!

Fortunately, there is a quantity, known as *cross-ratio*, that is preserved under all projective transformations. To see how this is defined, consider four collinear Points $A = [\mathbf{a}]$, $B = [\mathbf{b}]$, $C = [\mathbf{c}]$, $D = [\mathbf{d}]$ in RP^2. We can express the fact that A, B, C, D are collinear by writing $\mathbf{c}$ and $\mathbf{d}$ as linear combinations of $\mathbf{a}$ and $\mathbf{b}$. Thus we can write

$$\mathbf{c} = \quad \mathbf{a} + \quad \mathbf{b} \quad \text{and} \quad \mathbf{d} = \quad \mathbf{a} + \quad \mathbf{b},$$

for suitable real numbers , , , .

The cross-ratio is then defined to be the ratio of the ratios − and −.

Definition Let A, B, C, D be four collinear Points in $\mathbb{RP}^2$ represented by position vectors **a**, **b**, **c**, **d**, and let

$$\mathbf{c} = \quad \mathbf{a} + \quad \mathbf{b} \quad \text{and} \quad \mathbf{d} = \quad \mathbf{a} + \quad \mathbf{b}.$$

Then the **cross-ratio** of A, B, C, D is

$$(ABCD) = - \quad -.$$

Equivalently, we can write *(ABCD)* = —.

Of course, before we can be sure that this definition makes sense, we must ensure that it does not depend on the particular choice of position vectors **a**, **b**, **c**, **d** that are used to represent the Points A, B, C, D. We shall check this shortly, but first we illustrate how cross-ratios are calculated.

Example 1 Let $A = [1, 2, 3]$, $B = [1, 1, 2]$, $C = [3, 5, 8]$, $D = [1, \quad 1, 0]$ be Points of $\mathbb{RP}^2$. Calculate the cross-ratio *(ABCD)*.

Solution First, we have to find real numbers and such that the following vector equation holds:

$$(3, 5, 8) = \quad (1, 2, 3) + \quad (1, 1, 2).$$

Note that we have not verified that A, B, C, D are collinear; but if they were not, the equations for , , , could not be solved.

Comparing corresponding coordinates on both sides of this vector equation, we deduce that

$$3 = \quad + \quad, \quad 5 = 2 \quad + \quad \text{and} \quad 8 = 3 \quad + 2 \quad .$$

Solving these equations gives $= 2$, $= 1$.

Next, we find real numbers and such that the vector equation

$$(1, \quad 1, 0) = \quad (1, 2, 3) + \quad (1, 1, 2)$$

holds. Comparing corresponding coordinates on both sides of this vector equation, we deduce that

$$1 = \quad + \quad, \quad 1 = 2 \quad + \quad \text{and} \quad 0 = 3 \quad + 2 \quad .$$

Solving these equations gives $= \quad 2$, $= 3$.

It follows from the definition of cross-ratio that

$$(ABCD) = - \quad - = \frac{1}{2} \quad \frac{3}{2} = \quad \frac{1}{3}.$$

□

Problem 1 Calculate the cross-ratio *(ABCD)* for each of the following sets of collinear Points in $\mathbb{RP}^2$.

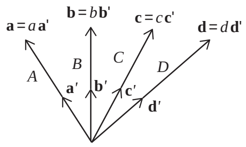
(a) $A = [1, \quad 1, \quad 1]$, $B = [1, 3, \quad 2]$, $C = [3, 5, \quad 5]$, $D = [1, \quad 5, 0]$
(b) $A = [1, 2, 3]$, $B = [2, 2, 4]$, $C = [\quad 3, \quad 5, \quad 8]$, $D = [3, \quad 3, 0]$

You may have noticed that the Points A, B, C, D in Problem l (b) are the same as those which appear in Example 1. The only difference is that different homogeneous coordinates are used to represent the Points in each case. As we mentioned after the definition of cross-ratio, the value of the cross-ratio *(ABCD)* does not depend on the homogeneous coordinates that are used to represent A, B, C, D, so it is not surprising that the cross-ratio turned out to have the value $\frac{1}{3}$ in both cases.

Theorem 1 The cross-ratio *(ABCD)* is independent of the homogeneous coordinates that are used to represent the collinear Points A, B, C, D.

Proof Suppose that $A = [\mathbf{a}]$, $B = [\mathbf{b}]$, $C = [\mathbf{c}]$, $D = [\mathbf{d}]$, and let

$$\mathbf{c} = \quad \mathbf{a} + \quad \mathbf{b} \quad \text{and} \quad \mathbf{d} = \quad \mathbf{a} + \quad \mathbf{b}. \tag{1}$$



Now suppose that $A = [\mathbf{a}\ ]$, $B = [\mathbf{b}\ ]$, $C = [\mathbf{c}\ ]$, $D = [\mathbf{d}\ ]$. Then

$$\mathbf{a} = a\mathbf{a}\ , \quad \mathbf{b} = b\mathbf{b}\ , \quad \mathbf{c} = c\mathbf{c}\ , \quad \mathbf{d} = d\mathbf{d}\ ,$$

where a, b, c, d are some non-zero real numbers.

By substituting these expressions into the equations (1), we obtain

$$c\mathbf{c} = \quad a\mathbf{a} + \quad b\mathbf{b} \quad \text{and} \quad d\mathbf{d} = \quad a\mathbf{a} + \quad b\mathbf{b}\ ,$$

which we can rewrite in the form

$$\mathbf{c} = \quad \mathbf{a} + \quad \mathbf{b} \quad \text{and} \quad \mathbf{d} = \quad \mathbf{a} + \quad \mathbf{b}\ , \tag{2}$$

where $\quad = a/c, \quad = b/c, \quad = a/d, \quad = b/d.$

We can now check that equations (1) and (2) yield the same value for the cross-ratio:

$$\begin{aligned} \text{—} \quad \text{—} &= \frac{b/c}{a/c} \quad \frac{b/d}{a/d} \\ &= \frac{b}{a} \quad \frac{b}{a} \\ &= \text{–} \quad \text{–}. \end{aligned}$$

So, as expected, the cross-ratio is independent of the choice of homogeneous coordinates.

The next problem illustrates that although the value of the cross-ratio *(ABCD)* is independent of the choice of homogeneous coordinates that are used to represent A, B, C, D, the value of the cross-ratio does depend on the order in which the Points A, B, C, D appear.

Problem 2 Calculate the cross-ratios *(BACD)* and *(ACBD)* for the four Points used in Problem l(a).

When answering Problem 2 you may have noticed that *(BACD)* is the reciprocal of the value which we obtained for *(ABCD)* in Problem 1(a). Also, *(ACBD)* is equal to 1 *(ABCD)*. The next result shows that this is not simply chance!

Note the way in which the Points are changed from their original ordering in the various cross-ratios. We take the reciprocal when swapping the first or last pair of Points, and we subtract from 1 when swapping the inner or outer pair of Points.

Theorem 2 Let A, B, C, D be four distinct collinear Points in $\mathbb{RP}^2$, and let $(ABCD) = k$. Then

$$(BACD) = (ABDC) = 1/k,$$

$$(ACBD) = (DBCA) = 1 \quad k.$$

Proof Let **a**, **b**, **c**, **d** be any position vectors in $\mathbb{R}^3$ in the directions of the Points A, B, C, D, respectively, of $\mathbb{RP}^2$, and let , , , be real numbers such that

$$\mathbf{c} = \ \mathbf{a} + \ \mathbf{b} \quad \text{and} \quad \mathbf{d} = \ \mathbf{a} + \ \mathbf{b}.$$

Then, by definition of cross-ratio, the cross-ratio $(ABCD)$ of the four Points A, B, C, D is the quantity

$$(ABCD) = \frac{\ }{\ } \quad \frac{\ }{\ } = \frac{\quad}{\quad} = k, \text{say}.$$

To determine $(BACD)$, we interchange the roles of A and B in the evaluation of $ABCD$ above; it follows that, since

$$\mathbf{c} = \ \mathbf{b} + \ \mathbf{a} \quad \text{and} \quad \mathbf{d} = \ \mathbf{d} + \ \mathbf{a},$$

the cross-ratio $(BACD)$ is the quantity

$$(BACD) = \frac{\ }{\ } \quad \frac{\ }{\ } = \frac{\quad}{\quad} = \frac{1}{k}.$$

To determine $(ABDC)$, we interchange the roles of C and D in the evaluation of $(ABCD)$ above; it follows that, since

$$\mathbf{d} = \ \mathbf{a} + \ \mathbf{b} \quad \text{and} \quad \mathbf{c} = \ \mathbf{a} + \ \mathbf{b},$$

the cross-ratio $(ABDC)$ is the quantity

$$(ABDC) = \frac{\ }{\ } \quad \frac{\ }{\ } = \frac{\quad}{\quad} = \frac{1}{k}.$$

This completes the first part of the proof.

To evaluate $(ACBD)$, we use the equations

$$\mathbf{c} = \ \mathbf{a} + \ \mathbf{b} \quad \text{and} \quad \mathbf{d} = \ \mathbf{a} + \ \mathbf{b} \tag{3}$$

to express **b** and **d** in terms of **a** and **c**, as follows.

From the first equation in (3) we have

$$\begin{aligned}\mathbf{b} &= (\mathbf{c} \qquad \mathbf{a})/ \\ &= (\quad / \quad)\mathbf{a} + (1/ \quad)\mathbf{c}. \end{aligned}\tag{4}$$

cannot be zero, for if it were then we would have **c** = **a**; this cannot happen since A and C are distinct Points.

If we then substitute this expression for **b** into the second equation in (3), we obtain

$$\begin{aligned}\mathbf{d} &= \quad \mathbf{a} + \quad ((\quad / \quad)\mathbf{a} + (1/ \quad)\mathbf{c}) \\ &= ((\qquad\qquad)/ \quad)\mathbf{a} + (\quad / \quad)\mathbf{c}. \end{aligned}\tag{5}$$

It follows from the coefficients of **a** and **c** in equations (4) and (5) that

$$\begin{aligned}(ACBD) &= \frac{1/}{\quad /} \quad \frac{/}{(\qquad\qquad)/} \\ &= \qquad \frac{}{\qquad\qquad} \\ &= 1 \quad \frac{}{\quad} \\ &= 1 \quad k. \end{aligned}$$

Finally, we can use the previous parts of the proof to evaluate $(DBCA)$, as follows:

This avoids the algebra involved in expressing **c** and **a** in terms of **d** and **b**.

$$\begin{aligned}(DBCA) &= 1/(BDCA) && \text{(swap first two Points)} \\ &= (BDAC) && \text{(swap last two Points)} \\ &= 1 \quad (BADC) && \text{(swap middle two Points)} \\ &= 1 \quad 1/(ABDC) && \text{(swap first two Points)} \\ &= 1 \quad (ABCD) && \text{(swap last two Points)} \\ &= 1 \quad k. \end{aligned}$$

Example 1

Earlier, we showed that the cross-ratio $(ABCD)$ of the four collinear Points $A = [1, 2, 3]$, $B = [1, 1, 2]$, $C = [3, 5, 8]$, $D = [1, \quad 1, 0]$ in $\mathbb{RP}^2$ is $\quad \frac{1}{3}$. Theorem 2 enables us to deduce that

$$\begin{aligned}(BACD) &= \quad 3, & (ABDC) &= \quad 3, \\ (ACBD) &= \tfrac{4}{3}, & (DBCA) &= \tfrac{4}{3}. \end{aligned}$$

Problem 3 Let the Points $A = [1, \quad 1, \quad 1]$, $B = [1, 3, \quad 2]$, $C = [3, 5, \quad 5]$, $D = [1, \quad 5, 0]$ be collinear Points of $\mathbb{RP}^2$. By applying Theorem 2 to the solution of Problem l(a), determine the values of the cross-ratios $(ABDC)$, $(DBCA)$ and $(ACBD)$.

The next theorem confirms that cross-ratio is preserved by projective transformations.

Theorem 3 Let t be a projective transformation, and let A, B, C, D be any four collinear Points in RP^2. If $A = t(A), B = t(B), C = t(C), D = t(D)$, then

$$(ABCD) = (A\ B\ C\ D).$$

Proof Let t be the projective transformation $t : [\mathbf{x}] \qquad [\mathbf{Ax}]$, where **A** is an invertible 3 × 3 matrix. If $A = [\mathbf{a}], B = [\mathbf{b}], C = [\mathbf{c}], D = [\mathbf{d}]$, and

$$\mathbf{a} = \mathbf{Aa},\ \mathbf{b} = \mathbf{Ab},\ \mathbf{c} = \mathbf{Ac},\ \mathbf{d} = \mathbf{Ad},$$

then $A = [\mathbf{a}],\ B = [\mathbf{b}],\ C = [\mathbf{c}],\ D = [\mathbf{d}]$.

Since A, B, C, D are collinear, we can write

$$\mathbf{c} = \quad \mathbf{a} + \quad \mathbf{b} \quad \text{and} \quad \mathbf{d} = \quad \mathbf{a} + \quad \mathbf{b}, \tag{6}$$

so

$$(ABCD) = - \quad -.$$

Multiplying each equation in (6) through by **A**, we obtain

$$\mathbf{c} = \quad \mathbf{a} + \quad \mathbf{b} \quad \text{and} \quad \mathbf{d} = \quad \mathbf{a} + \quad \mathbf{b},$$

so that

$$(A\ B\ C\ D) = - \quad -.$$

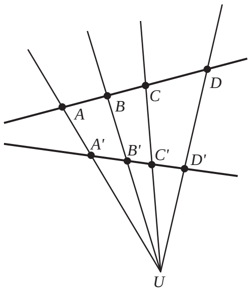
It follows that

$$(A\ B\ C\ D) = (ABCD).$$

We now use Theorem 3 to prove that if four distinct Points on a Line are in perspective with four distinct Points on another Line, then the cross-ratios of the four Points on each Line are equal.

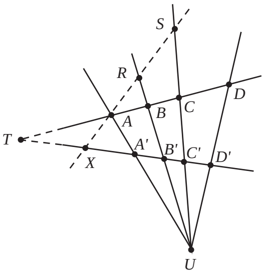
Theorem 4 Let A, B, C, D be four distinct Points on a Line, and let A, B, C, D be four distinct Points on another Line such that AA, BB, CC, DD all meet at a Point U. Then

$$(ABCD) = (A\ B\ C\ D).$$



Proof By the Fundamental Theorem of Projective Geometry, there is a unique projective transformation t which maps B to B, C to C, B to B, and C to C. We shall show that $t(A) = A$ and $t(D) = D$, and hence by Theorem 3 it follows that $(ABCD) = (A\ B\ C\ D)$.

First observe that the composite $t \quad t$ fixes the Points B, C, B and C. By the Fundamental Theorem of Projective Geometry, the only projective transformation which does this is the identity transformation, so $t \quad t = i$ and $t = t^{\ 1}$.



Next observe that t maps the Line BC onto the Line $B\ C$, and vice versa; so the Point T at which BC and $B\ C$ intersect must be fixed by t. Also, t maps the Lines BB and CC onto themselves, so their Point of intersection U must be fixed by t.

Now let X be the image of A under t. Then X lies on $B\ C$. We want to show that $X = A$.

Suppose that $X = A$; then AX cannot pass through U so it must intersect BB at R and CC at S, where R, S and U are distinct Points.

Since t is self-inverse, it maps X back to A and therefore maps AX onto itself. But this implies that t fixes the four Points R, S, T, U; so by the Fundamental Theorem of Projective Geometry t must be the identity transformation. This is a contradiction with the hypothesis that the Lines $ABCD$ and $A\ B\ C\ D$ are different. It follows that we must conclude that $X = A$, that is, $t(A) = A$. A similar argument shows that $t(D) = D$.

Finally, it follows by Theorem 3 that $(ABCD) = (A\ B\ C\ D\ )$, as required.

In affine geometry, if we are given two points A and B, then the ratio AC/CB uniquely determines a third point C on the line AB. We now explore the analogous result for projective geometry, namely that if we are given any three collinear Points A, B, C in $\mathbb{RP}^2$, then the value of the cross-ratio $(ABCD)$ uniquely determines a fourth Point D.

Theorem 5 Unique Fourth Point Theorem

Let A, B, C, X, Y be collinear Points in $\mathbb{RP}^2$ such that

$$(ABCX) = (ABCY).$$

Then $X = Y$.

Proof Let $A = [\mathbf{a}]$, $B = [\mathbf{b}]$, $C = [\mathbf{c}]$, $X = [\mathbf{x}]$, $Y = [\mathbf{y}]$. Since A, B, C, X, Y are collinear, it follows that there are real numbers , , , , μ such that

$$\mathbf{c} = \ \mathbf{a} + \ \mathbf{b}, \quad \mathbf{x} = \ \mathbf{a} + \ \mathbf{b} \quad \text{and} \quad \mathbf{y} = \ \mathbf{a} + \mu\mathbf{b}. \tag{7}$$

Then

$$(ABCX) = \frac{\ }{\ } \quad \text{and} \quad (ABCY) = \frac{\ }{\mu}.$$

Since $(ABCX) = (ABCY)$, it follows that

This is the hypothesis of the theorem.

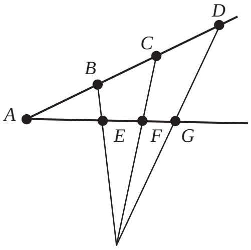
$$\frac{\ }{\ } = \frac{\ }{\mu},$$

so $= \mu/$. If we substitute this value of into the expression for $\mathbf{y}$ in equation (7), we obtain

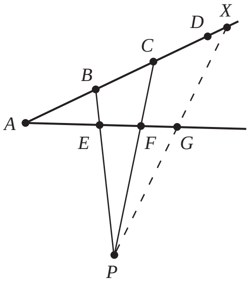
$$\mathbf{y} = (\ \mu/\ )\mathbf{a} + \mu\mathbf{b} = (\mu/\ )(\ \mathbf{a} + \ \mathbf{b}) = (\mu/\ )\mathbf{x}.$$

Since $\mathbf{y}$ is a scalar multiple of $\mathbf{x}$, it follows that $X = Y$, as required.

In Theorem 4 we showed that the cross-ratios $(ABCD)$ and $(A\ B\ C\ D\ )$ are equal if the Points $A\ , B\ , C\ , D$ are in perspective with the Points A, B, C, D. Our next result is a partial converse of this result.



Theorem 6 Let A, B, C, D and A, E, F, G be two sets of collinear Points (on different Lines in $\mathbb{RP}^2$) such that the cross-ratios $(ABCD)$ and $(AEFG)$ are equal. Then the Lines BE, CF and DG are concurrent.



Proof Let P be the Point at which the Lines BE and CF meet, and let X be the Point at which the Line PG meets the Line $ABCD$. Then the Points A, B, C and X are in perspective from P with the Points A, E, F and G, so that

$$(ABCX) = (AEFG).$$

Since we know that $(AEFG) = (ABCD)$, it follows that

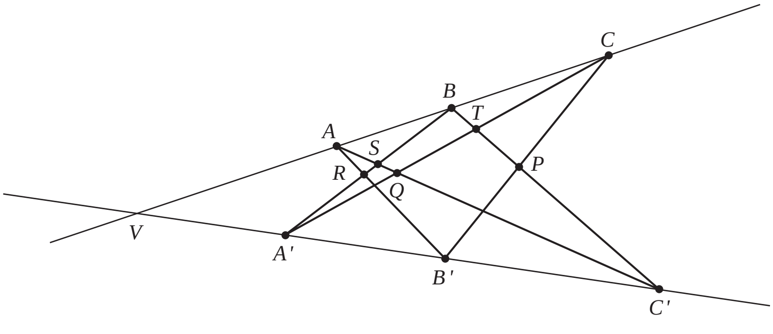
$$(ABCX) = (ABCD).$$

By Theorem 5, we must therefore have $X = D$. Hence the Points A, B, C, D and the Points A, E, F, G are in perspective from P.

We can now use Theorem 6 together with the other properties of cross-ratio to give a second proof of Pappus Theorem.

Theorem 7 Pappus' Theorem
Let A, B and C be three Points on a Line in $\mathbb{RP}^2$, and let $A\ , B$ and C be three Points on another Line. Let BC and $B\ C$ meet at P, CA and $C\ A$ meet at Q, and AB and $A\ B$ meet at R. Then P, Q and R are collinear.

You met this Theorem earlier, in Subsection 3.4.1.



Proof Let V be the Point of intersection of the two given Lines. Also let the Lines BA and AC meet at the Point S, and the Lines BC and CA meet at the Point T.

Now, the Points $V, A\ , B\ , C$ are in perspective from A with the Points B, $A\ , R, S$, so that

$$(VA\ B\ C\ ) = (BA\ RS). \tag{8}$$

By Theorem 4

Similarly, the Points V, A', B', C' are in perspective from C with the Points B, T, P, C', so that

$$(VA'B'C') = (BTPC'). \tag{9}$$

It follows from equations (8) and (9) that

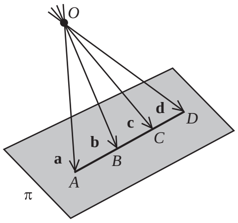
$$(BA'RS) = (BTPC'),$$

so that by Theorem 6 the Lines $A'T, RP, SC'$ are concurrent.

We may rephrase this statement as follows: the Line RP passes through the Point where $A'T$ meets SC'; that is, the Line RP passes through Q. In other words, P, Q and R are collinear.

3.5.2 Cross-Ratio on Embedding Planes

So far, we have calculated a given cross-ratio $(ABCD)$ by applying the definition of cross-ratio directly to the Points A, B, C, D. However, it is sometimes convenient to evaluate the cross-ratio by examining the representation of the Points on some embedding plane.



See Appendix 2.

Suppose that four collinear Points of $\mathbb{RP}^2$ pierce an embedding plane π at the points A, B, C, D with position vectors **a**, **b**, **c**, **d**, respectively.

According to the Section Formula, we can write **c** and **d** in the form

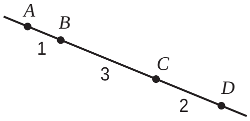
$$\mathbf{c} = \lambda\mathbf{a} + (1-\lambda)\mathbf{b} \quad \text{and} \quad \mathbf{d} = \mu\mathbf{a} + (1-\mu)\mathbf{b},$$

where $(1-\lambda) : \lambda$ is the ratio $AC : CB$, and $(1-\mu) : \mu$ is the ratio $AD : DB$. Then from the definition of cross-ratio

$$(ABCD) = \frac{1-\lambda}{\lambda} \div \frac{1-\mu}{\mu},$$

so

$$(ABCD) = \frac{AC}{CB} \div \frac{AD}{DB}. \tag{10}$$



Example 2 In an embedding plane, the points A, B, C, D lie in order along a line with the distances AB, BC, CD being 1 unit, 3 units and 2 units, respectively. Determine the cross-ratios $(ABCD)$, $(BACD)$ and $(ACBD)$.

Solution Using equation (10) and the sign convention for ratios, we have

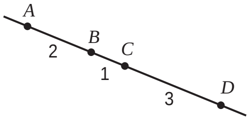
$$(ABCD) = \frac{AC}{CB} \div \frac{AD}{DB} = \frac{4}{3} \div -\frac{6}{5} = -\frac{10}{9},$$

$$(BACD) = \frac{BC}{CA} \div \frac{BD}{DA} = -\frac{3}{4} \div -\frac{5}{6} = \frac{9}{10}$$

and

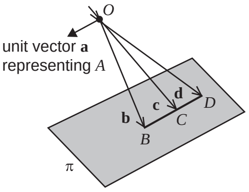
$$(ACBD) = \frac{AB}{BC} \quad \frac{AD}{DC} = \frac{1}{3} \qquad \frac{6}{2} = \frac{1}{9}. \qquad \square$$

Problem 4 The points A, B, C, D lie in order along a line with the distances AB, BC, CD being 2 units, 1 unit and 3 units, respectively. Determine the cross-ratios $(ABCD)$ and $(DBCA)$.



Sometimes one of the Points whose cross-ratio we are trying to find turns out to be an ideal Point for the embedding plane. In such cases, formula (10) cannot be used since some of the distances in the formula will not be defined.

To be specific, suppose that the Points A, B, C, D are collinear, but that A is an ideal Point for the embedding plane , as shown in the margin. As before, we can let **b**, **c**, **d** be the position vectors of the points B, C, D on , but we take **a** to be a unit vector along A. Then



$$\mathbf{c} = \quad (CB)\mathbf{a} + \mathbf{b} \quad \text{and} \quad \mathbf{d} = \quad (DB)\mathbf{a} + \mathbf{b}.$$

From the definition of cross-ratio, it follows that

$$(ABCD) = \frac{1}{CB} \quad \frac{1}{DB} = \frac{DB}{CB}. \tag{11}$$

We can now obtain the corresponding formulas for the cases where B, C or D is an ideal Point, by applying Theorem 2. For example, if B is an ideal Point, then

$$\begin{aligned}(ABCD) &= \frac{1}{(BACD)} && \text{(swap first two terms)}\\ &= (BADC) && \text{(swap last two terms)}\\ &= \frac{CA}{DA} && \text{by equation (11).}\end{aligned}$$

Problem 5 Use Theorem 2 To prove that:

(a) $(ABCD) = \frac{AC}{BC}$ if D is an ideal Point;
(b) $(ABCD) = \frac{BD}{AD}$ if C is an ideal Point.

We now summarize the various formulas for cross-ratio in the form of a strategy, as follows.

Strategy To use an embedding plane to calculate the cross-ratio of four collinear Points:

1. if the four Points pierce the embedding plane at A, B, C, D, then

$$(ABCD) = \frac{AC}{CB} \quad \frac{AD}{DB};$$

2. if one of the Points is an ideal Point for the embedding plane, then

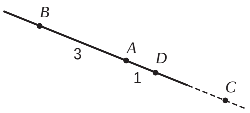
$$(ABCD) = \frac{DB}{CB} \text{ if } A \text{ is ideal,}$$

$$(ABCD) = \frac{CA}{DA} \text{ if } B \text{ is ideal,}$$

$$(ABCD) = \frac{BD}{AD} \text{ if } C \text{ is ideal,}$$

$$(ABCD) = \frac{AC}{BC} \text{ if } D \text{ is ideal.}$$

Example 3 Determine $(ABCD)$ for the collinear points A, B, C, D illustrated in the margin, where C is an ideal Point.

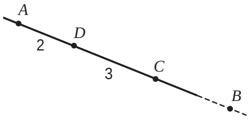


Solution Since C is an ideal Point, we have

$$(ABCD) = \frac{BD}{AD} = \frac{4}{1} = 4.$$

□

Problem 6 Determine $(ABCD)$ for the collinear points A, B, C, D illustrated in the margin, where B is an ideal Point.



3.5.3 An Application of Cross-Ratio

Earlier, we described how projective geometry can be used to obtain two-dimensional representations of three-dimensional scenes. We now describe how cross-ratios can be used to obtain information about a three-dimensional scene from a two-dimensional representation of the scene. We do this in the context of aerial photography.

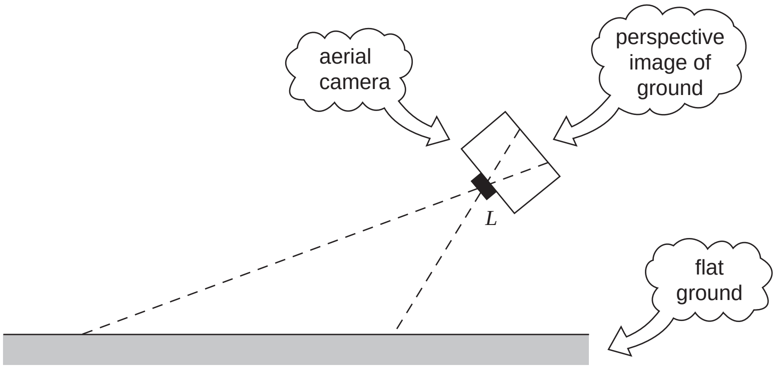
Subsection 3.1.1

For simplicity, consider an aerial camera that takes pictures on a flat film behind its lens, L, of features on a flat piece of land in front of L. Since a point on the ground lies on the same line through L as its image on the film, we can regard the process of taking a photograph as a perspectivity centred at L.

Since collinearity is invariant under a perspectivity, the image of any line on the ground is a line on the film. Moreover, the cross-ratio of any four collinear points is invariant under a perspectivity, so the cross-ratio of any four points on must be equal to the cross-ratio of their images on the film.

Section 3.3, Theorem 2

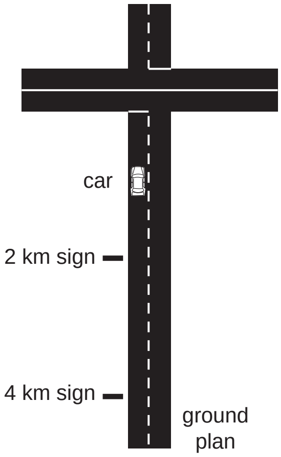
Theorem 3



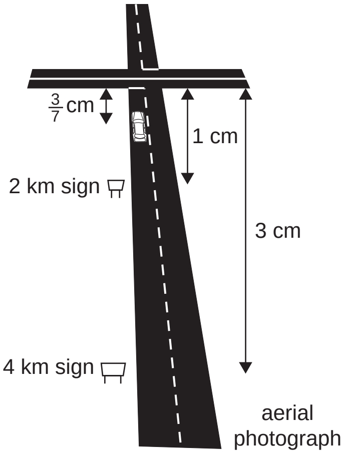
aerial camera
perspective image of ground
L
flat ground

Example 4 An aerial camera photographs a car travelling along a straight road on flat ground towards a junction. Before the junction there are two warning signs at distances of 4 km and 2 km from the junction. On the film the signs are 1 cm and 3 cm from the junction, and the car is $\frac{3}{7}$ cm from the junction. How far is the car from the junction on the ground?

Strictly speaking, the car is not in line with the two signposts. Consequently, the distances marked on the photograph are approximations measured along the line of the left-hand kerb of the road.



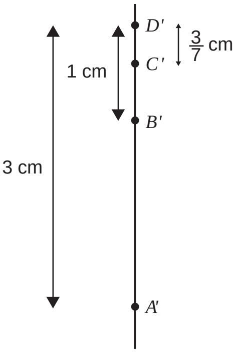
car
2 km sign
4 km sign
ground plan



$\frac{3}{7}$ cm
1 cm
2 km sign
3 cm
4 km sign
aerial photograph

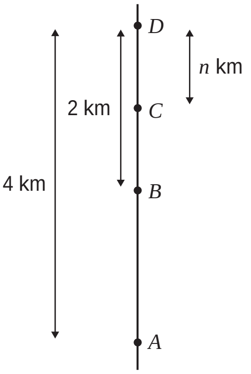
Solution Let A and B denote the signs, C denote the car, and D denote the junction, and let A', B', C', D' be their images on the film. Then

$$\begin{aligned}(A'B'C'D') &= \frac{A'C'}{C'B'} \div \frac{A'D'}{D'B'} \\ &= \frac{18/7}{4/7} \div \frac{3}{1} \\ &= \frac{3}{2}.\end{aligned}$$



D′
C′
B′
A′
$\frac{3}{7}$ cm
1 cm
3 cm

Now let the car be n km from the junction. Then



$$\begin{aligned}(ABCD) &= \frac{AC}{CB} \div \frac{AD}{DB}\\ &= \frac{4-n}{2-n} \div \frac{4}{2}\\ &= \frac{4-n}{2(2-n)}.\end{aligned}$$

Since $(ABCD)$ and $(A'B'C'D')$ must be equal, it follows that

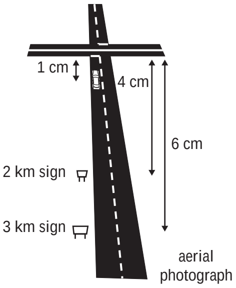
$$\frac{4-n}{2(2-n)} = \frac{3}{2}.$$

Hence

$$4-n = 3(2-n).$$

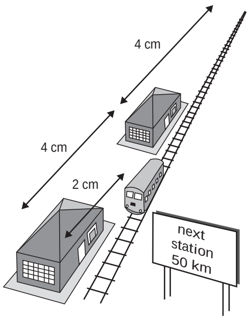
and so $n = 1$. That is, the car is 1 km from the junction. □

Problem 7 An aerial camera photographs a car travelling along a straight road on flat ground towards a junction. Before the junction there are two warning signs, at distances of 2 km and 3 km from the junction. On the film the signs are 4 cm and 6 cm from the junction, and the car is 1 cm from the junction. How far is the car from the junction on the ground?



If two lines that are known to be parallel on the ground appear to meet on the film, then the point of intersection on the film corresponds to the ideal Point where the ‘parallel lines meet’. We can therefore use the above technique even when one of the Points is ideal, for we can use the second part of the strategy in Subsection 3.5.2 to calculate the cross-ratio whenever one of the Points is ideal.

Problem 8 An aerial camera photographs a train travelling between two stations along a straight track on flat ground. The stations are 50 km apart. When the film is inspected, the stations are 4 cm apart, the train is midway between the stations, and the rails appear to meet (or vanish) 4 cm beyond the station towards which the train is travelling. How far has the train to travel to the next station?



3.6 Exercises

Section 3.2

1. (a) Write down numbers a, b, c and d such that

$$[1, a, b] = \quad \tfrac{1}{2}, 3, 4 \qquad \text{and} \qquad [c, d, 2] = [3, 0, 1].$$

   (b) Which of the following homogeneous coordinates represent the same Point of $\mathbb{RP}^2$ as $[4, \quad 8, 2]$?

$$\text{(i) } [1, 4, \quad 2] \qquad \text{(ii) } \quad \tfrac{1}{4}, \quad \tfrac{1}{2}, \tfrac{1}{8} \qquad \text{(iii) } \quad \tfrac{1}{2}, \quad 2, 1$$

$$\text{(iv) } [\quad 2, 4, \quad 1] \qquad \text{(v) } \quad \tfrac{1}{8}, \quad \tfrac{1}{2}, \tfrac{1}{4}$$

2. Determine an equation for each of the following Lines in $\mathbb{RP}^2$:
   (a) the Line through the Points [1, 2, 3] and [3, 0, 2];
   (b) the Line through the Points [1, 1, 1] and [2, 1, 3].
3. Determine whether each of the following sets of Points are collinear:
   (a) [1, 1, 0], [1, 0, 1] and [2, 1, 1];
   (b) [1, 0, 1], [0, 1, 2] and [1, 2, 3].
4. Determine the Point of intersection of each of the following pairs of Lines in $\mathbb{RP}^2$:
   (a) the Lines with equations $x \quad 2y + z = 0$ and $x \quad y \quad z = 0$;
   (b) the Lines with equations $x + 2y + 5z = 0$ and $3x \quad y + z = 0$.
5. Determine the Point of $\mathbb{RP}^2$ at which the Line through the Points [8, 1, 2] and [1, 2, 1] meets the Line through the Points [0, 1, 1] and [2, 3, 1].
6. Determine the Point of $\mathbb{RP}^2$ at which the Line through the Points [1, 2, 2] and [2, 3, 3] meets the Line through the Points [0, 1, 2] and [0, 1, 3].

Section 3.3

In these exercises, you may find the following list of matrices and their inverses useful.

$$\mathbf{A}: \quad \begin{matrix} 2 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 1 \end{matrix} \qquad \begin{matrix} 2 & 0 & 1 \\ 0 & 3 & 2 \\ 1 & 3 & 1 \end{matrix} \qquad \begin{matrix} 0 & 3 & 1 \\ 2 & 0 & 1 \\ 0 & 0 & 1 \end{matrix} \qquad \begin{matrix} 0 & 3 & 4 \\ 1 & 3 & 2 \\ 3 & 3 & 3 \end{matrix}$$

$$\mathbf{A}^{\ 1}: \quad \begin{matrix} 1 & 1 & 1 \\ 1 & 2 & 2 \\ 1 & 2 & 1 \end{matrix} \qquad \begin{matrix} 1 & 1 & 1 \\ \frac{2}{3} & 1 & \frac{4}{3} \\ 1 & 2 & 2 \end{matrix} \qquad \begin{matrix} 0 & \frac{1}{2} & \frac{1}{2} \\ \frac{1}{3} & 0 & \frac{1}{3} \\ 0 & 0 & 1 \end{matrix} \qquad \begin{matrix} 5 & 7 & 2 \\ 3 & 4 & \frac{4}{3} \\ 2 & 3 & 1 \end{matrix}$$

1. Determine which of the following transformations t of $\mathbb{RP}^2$ are projective transformations. For those that are projective transformations, write down a matrix associated with t.

(a) $t : [x, y, z] \quad [2x, y + 3z, 1]$
(b) $t : [x, y, z] \quad [x, x \ \ y + 3z, x + y]$
(c) $t : [x, y, z] \quad [2y, y \ \ 4z, x]$
(d) $t : [x, y, z] \quad [x + y \ \ z, y + 3z, x + 2y + 2z]$

2. Determine the images of the Points [1, 2, 3], [0, 1, 0] and [1, $\ $ 1, 1] under the projective transformation t associated with the matrix

$$\mathbf{A} = \begin{matrix} 2 & 0 & 1 \\ 1 & 1 & 0 \\ 0 & 1 & 1 \end{matrix} .$$

3. Let

$$t_1 : [x, y, z] \quad [2x + y, \ \ x + z, y + z],$$
$$t_2 : [x, y, z] \quad [x + y, 3x \ \ z, 4y \ \ 2z]$$

be projective transformations from $\mathbb{R}P^2$ to $\mathbb{R}P^2$.
(a) Write down matrices associated with each of t_1 and t_2.
(b) Determine formulas for $t_2 \quad t_1$ and $t_2 \quad t_1^{\ 1}$.

4. Find the image of the Line $x + 2y + 3z = 0$ under the projective transformation t_1 defined in Exercise 3.

5. Determine matrices for the projective transformations which map the Points [1, 0, 0], [0, 1, 0], [0, 0, 1] and [1, 1, 1] onto the following Points:
(a) [$\ $ 2, 0, 1], [0, 1, $\ $ 1], [$\ $ 1, 2, $\ $ 1] and [$\ $ 1, 1, $\ $ 1];
(b) [0, 1, 0], [1, 0, 0], [$\ $ 1, $\ $ 1, 1] and [2, 1, 1];
(c) [0, 1, $\ $ 3], [1, 1, $\ $ 1], [4, 2, 3] and [7, 4, 3].

6. Use the results of Exercise 5 to determine the projective transformations that map:
(a) the Points

$$[\ \ 2, 0, 1],\ [0, 1, \ \ 1],\ [\ \ 1, 2, \ \ 1],\ [\ \ 1, 1, \ \ 1]$$

to the Points

$$[0, 1, 0],\ [1, 0, 0],\ [\ \ 1, \ \ 1, 1],\ [2, 1, 1],$$

respectively;
(b) the Points

$$[0, 1, 0],\ [1, 0, 0],\ [\ \ 1, \ \ 1, 1],\ [2, 1, 1]$$

to the Points

$$[0, 1, \ \ 3],\ [1, 1, \ \ 1],\ [4, 2, 3],\ [7, 4, 3],$$

respectively;
(c) the Points

$$[0, 1, \ \ 3],\ [1, 1, \ \ 1],\ [4, 2, 3],\ [7, 4, 3]$$

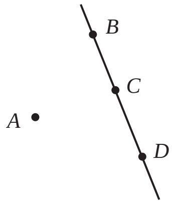
to the Points

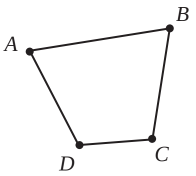
$$[\ \ 2, 0, 1],\ [0, 1, \ \ 1],\ [\ \ 1, 2, \ \ 1],\ [\ \ 1, 1, \ \ 1],$$

respectively.

Section 3.4

1. For which of the following configurations of Points A, B, C and D in $\mathbb{RP}^2$ is there a projective transformation sending A, B, C to the triangle of reference and D to the unit Point?

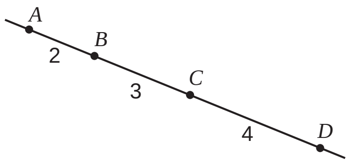




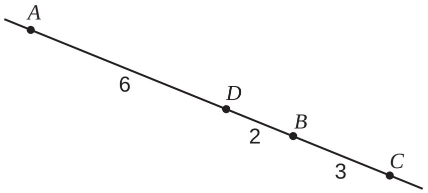
2. Let ABC be a triangle in $\mathbb{R}^2$, and let U be any point of $\mathbb{R}^2$ that is not collinear with any two of the points A, B, C. Let the Lines BC and AU meet at P, CA and BU meet at Q, and AB and CU meet at R. Prove that P, Q, R cannot be collinear.

Section 3.5

1. For each of the following sets of Points A, B, C, D, calculate the cross-ratio $(ABCD)$.
   (a) $A = [2, 1, 3],\ B = [1, 2, 3],\ C = [8, 1, 9],\ D = [4, \ 1, 3]$
   (b) $A = [2, 1, 1],\ B = [\ 1, 1, \ 1],\ C = [1, 2, 0],\ D = [\ 1, 4, \ 2]$
   (c) $A = [\ 1, 1, 1],\ B = [0, 0, 2],\ C = [5, \ 5, 3],\ D = [\ 3, 3, 7]$
2. For the Points A, B, C, D in Exercise 1(a), determine the cross-ratios $(BACD)$, $(BDCA)$ and $(ADBC)$.
3. For each set of collinear points A, B, C, D illustrated below, calculate the cross-ratio $(ABCD)$.

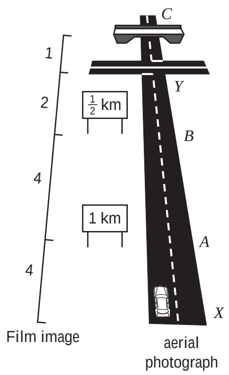


(a)



(b)

4. Calculate the cross-ratio $(ABCD)$ for the collinear points A, B, C, D illustrated below, where D is an ideal Point.



5. The diagram in the margin represents an aerial photograph of a straight road on flat ground. At A there is a sign Junction 1 km , at B a sign Junction

$\frac{1}{2}$ km , and C is the road junction. Also, a police patrol car is at X, and a bridge is at Y. The distances marked on the left of the diagram are measured in cm from the photograph.

Calculate the actual distances (in km) of the patrol car and the bridge from the junction.

Summary of Chapter 3

Section 3.1: Perspective

1. Renaissance artists used **terraced perspective** and later **vertical perspective** in an attempt to portray real scenes in a realistic way. The modern system of **focused perspective** was discovered by Brunelleschi and finally perfected by Leonardo da Vinci; it is well illustrated by the woodcuts of Albrecht Dürer.

   The family of lines joining an eye to each point of a scene meets a screen in front of the eye, and the image on the screen is called a **cross-section** (or **section**). The cross-section gives a realistic two-dimensional representation of the three-dimensional scene.
2. For two planes and that do not pass through the origin O in $\mathbb{R}^3$, points P in and Q in are **in perspective from *O*** if there is a straight line through O, P and Q.

   A **perspectivity from to** centred at O is a function that maps a point P of to a point Q of whenever P and Q are in perspective from O. (The planes and may lie on the same or on opposite sides of O.)
3. The domain of a perspectivity may not be the whole of ; for, if P is any point of such that OP is parallel to to , then P cannot have an image in .

   The image of a line under a perspectivity is another line, possibly minus one point.

   Foreshortening is the effect under a perspectivity of lines of equal lengths at different distances from a screen corresponding to different lengths on the screen.
4. Two parallel lines in a horizontal plane appear to an observer to meet at a **vanishing point** on a vertical screen ; this is the **principal vanishing point** if the lines are perpendicular to the line of intersection of and , and a **diagonal vanishing point** otherwise.

   The family of vanishing points is a line, the **vanishing line**, that corresponds to the horizon line in a picture.
5. **Desargues' Theorem** Let ABC and $A\ B\ C$ be triangles in $\mathbb{R}^2$ such that the lines AA , BB and CC meet at a point U. Let BC and $B\ C$ meet at P, CA and $C\ A$ meet at Q, and AB and $A\ B$ meet at R. Then P, Q and R are collinear.

Section 3.2: The Projective Plane $\mathbb{RP}^2$

1. A **Point** (or **projective point**) is a line in $\mathbb{R}^3$ that passes through the origin of $\mathbb{R}^3$.

   The **real projective plane** $\mathbb{RP}^2$ is the set of all such Points.
2. The expression $[a,b,c]$, in which the numbers a, b and c are not all zero, represents the Point P of $\mathbb{RP}^2$ which consists of the unique line in $\mathbb{R}^3$ that passes through (0,0,0) and (a,b,c). We refer to $[a,b,c]$ as **homogeneous coordinates** of P.

   If (a,b,c) has position vector **v**, then we often denote P by [**v**] and we say that P can be **represented** by **v**.

   It makes NO sense to write the expression [0,0,0], since not all of a, b and c can be zero.
3. The homogeneous coordinates $[a,b,c]$ and $[\lambda a, \lambda b, \lambda c]$ (where $\lambda \neq 0$) represent the same Point of $\mathbb{RP}^2$; that is, $[a,b,c] = [\lambda a, \lambda b, \lambda c]$, for any $\lambda \neq 0$.

   If there is no non-zero real number λ such that $[a,b,c] = \left[\lambda a', \lambda b', \lambda c'\right]$, then the homogeneous coordinates $[a,b,c]$ and $\left[a', b', c'\right]$ represent different Points of $\mathbb{RP}^2$.

   Further, $\left[a', b', 1\right] = \left[a'', b'', 1\right]$ if and only if $a' = a''$ and $b' = b''$.
4. A **projective figure** is a subset of $\mathbb{RP}^2$.
5. A **Line** (or **projective line**) in $\mathbb{RP}^2$ is a plane in $\mathbb{R}^3$ that passes through the origin. Points of $\mathbb{RP}^2$ are **collinear** if they lie on a Line.
6. The general equation of a Line in $\mathbb{RP}^2$ is $ax + by + cz = 0$, where a, b, c are real and not all zero.
7. **Collinearity Property of** $\mathbb{RP}^2$ Any two distinct Points of $\mathbb{RP}^2$ lie on a unique Line.

   Strategy To determine an equation for the Line in $\mathbb{RP}^2$ through the Points $\left[d,e,f\right]$ and $\left[g,h,k\right]$:

   1. write down the equation $\begin{vmatrix} x & y & z \\ d & e & f \\ g & h & k \end{vmatrix} = 0$;
   2. expand the determinant in terms of the entries in its first row to obtain the required equation in the form $ax + by + cz = 0$.

   Sometimes it is possible to 'spot' the equation of a Line through two Points without using the determinant.
8. **Strategy** To determine whether three Points $[a,b,c]$, $[d,e,f]$ and $[g,h,k]$ are collinear:

   1. evaluate the determinant $\begin{vmatrix} a & b & c \\ d & e & f \\ g & h & k \end{vmatrix}$;
   2. the Points $[a,b,c]$, $[d,e,f]$ and $[g,h,k]$ are collinear if and only if this determinant is zero.
9. The Points [1,0,0], [0,1,0], [0,0,1] are known as the **triangle of reference**. The Point [1,1,1] is called the **unit Point**.

10. **Incidence Property of** $\mathbb{RP}^2$ Any two distinct Lines in $\mathbb{RP}^2$ intersect in a unique Point of $\mathbb{RP}^2$.
11. Let be any plane in $\mathbb{R}^3$ that does not pass through the origin O. Then there is a one-one correspondence between the points of and those Points of $\mathbb{RP}^2$ which pierce . Those Points of $\mathbb{RP}^2$ which do not pierce are called **ideal Points** for .

    The set of ideal Points for is a plane through O parallel to , called the **ideal Line** for .
12. An **embedding plane** is a plane, , which does not pass through the origin, together with the set of all ideal Points for .

    The plane in $\mathbb{R}^3$ with equation $z = 1$ is called the **standard embedding plane**. The mapping of $\mathbb{RP}^2$ into the standard embedding plane is called the **standard embedding** of $\mathbb{RP}^2$.
13. Parallelism is not a projective property.

Section 3.3: Projective Transformations

1. A **projective transformation** of $\mathbb{RP}^2$ is a function t: $\mathbb{RP}^2$ $\mathbb{RP}^2$ of the form $t : [\mathbf{x}]$ $[\mathbf{Ax}]$, where $\mathbf{A}$ is an invertible 3 × 3 matrix. We say that $\mathbf{A}$ is a matrix **associated** with t. The set of all projective transformations is denoted by $P(2)$.

   If $\mathbf{A}$ is a matrix **associated** with t, then so is $\mathbf{A}$ for any non-zero number .
2. The set of projective transformations $P(2)$ forms a group under the operation of composition of functions. In particular, if t_1 and t_2 are projective transformations with associated matrices $\mathbf{A}_1$ and $\mathbf{A}_2$, respectively, then $t_1 \ t_2$ and $t_1^{\ 1}$ are projective transformations with associated matrices $\mathbf{A}_1\mathbf{A}_2$ and $\mathbf{A}_1^{\ 1}$.

   Strategy To compose two projective transformations t_1 and t_2:
   1. write down matrices $\mathbf{A}_1$ and $\mathbf{A}_2$ associated with t_1 and t_2;
   2. calculate $\mathbf{A}_1\mathbf{A}_2$;
   3. write down the composite $t_1 \ t_2$ with which $\mathbf{A}_1\mathbf{A}_2$ is associated.

   Strategy To find the inverse of a projective transformation t:
   1. write down a matrix $\mathbf{A}$ associated with t;
   2. calculate $\mathbf{A}^{\ 1}$;
   3. write down the inverse $t^{\ 1}$ with which $\mathbf{A}^{\ 1}$ is associated.
3. **Strategy** To find the image of a Line $ax + by + cz = 0$ under a projective transformation $t : [\mathbf{x}]$ $[\mathbf{Ax}]$:
   1. write the equation of the Line in the form $\mathbf{Lx} = 0$, where $\mathbf{L}$ is the matrix $(a\,b\,c)$;
   2. find a matrix $\mathbf{B}$ associated with $t^{\ 1}$;
   3. write down the equation of the image as $(\mathbf{LB})\,\mathbf{x} = 0$.
4. **Projective geometry** is the study of those properties of figures in $\mathbb{RP}^2$ that are preserved by projective transformations. Collinearity and incidence are both projective properties.

5. A **quadrilateral** is a set of four Points A, B, C and D (no three of which are collinear), together with the Lines AB, BC, CD and DA.
   All quadrilaterals are projective-congruent.
6. **Strategy** To find the projective transformation which maps [1,0,0] to $[a_1, a_2, a_3]$, [0,1,0] to $[b_1, b_2, b_3]$, [0,0,1] to $[c_1, c_2, c_3]$, [1,1,1] to $[d_1, d_2, d_3]$, where no three of $[a_1, a_2, a_3]$, $[b_1, b_2, b_3]$, $[c_1, c_2, c_3]$ and $[d_1, d_2, d_3]$ are collinear:
   1. find u, v, w for which $\begin{matrix} a_1 u & b_1 \mathsf{v} & c_1 \mathsf{w} \\ a_2 u & b_2 \mathsf{v} & c_2 \mathsf{w} \\ a_3 u & b_3 \mathsf{v} & c_3 \mathsf{w} \end{matrix} \quad \begin{matrix} 1 \\ 1 \\ 1 \end{matrix} = \begin{matrix} d_1 \\ d_2 \\ d_3 \end{matrix}$;
   2. write down the required projective transformation in the form t: $[\mathbf{x}] \quad [\mathbf{Ax}]$, where $\mathbf{A}$ is any non-zero real multiple of the matrix $\begin{matrix} a_1 u & b_1 \mathsf{v} & c_1 \mathsf{w} \\ a_2 u & b_2 \mathsf{v} & c_2 \mathsf{w} \\ a_3 u & b_3 \mathsf{v} & c_3 \mathsf{w} \end{matrix}$.
7. **Fundamental Theorem of Projective Geometry** Let $ABCD$ and $A\ B\ C\ D$ be two quadrilaterals in $\mathbb{RP}^2$. Then:
   (a) there is a projective transformation t which maps A to A , B to B , C to C , D to D ;
   (a) the projective transformation t is unique.
8. **Strategy** To determine the projective transformation t which maps the vertices of the quadrilateral $ABCD$ to the corresponding vertices of the quadrilateral $A\ B\ C\ D$:
   1. find the projective transformation t_1 which maps the triangle of reference and unit Point to the Points A, B, C, D, respectively;
   2. find the projective transformation t_2 which maps the triangle of reference and unit Point to the Points A , B , C , D , respectively;
   3. calculate $t = t_2 \quad t_1{}^{1}$.
9. With any given perspectivity we can construct an associated **perspective transformation** that is a one-one mapping of {the ideal Points for } onto the ideal Points for . This maps $\mathbb{RP}^2$ onto itself.
   Every projective transformation can be expressed as the composite of three perspective transformations.

Section 3.4: Using the Fundamental Theorem of Projective Geometry

1. **Desargues' Theorem** Let ABC and $A\ B\ C$ be triangles in $\mathbb{R}^2$ such that the lines AA , BB and CC meet at a point U. Let BC and $B\ C$ meet at P, CA and $C\ A$ meet at Q, and AB and $A\ B$ meet at R. Then P, Q and R are collinear.
2. The Fundamental Theorem is often used to simplify proofs of results in projective geometry, where the properties involved are projective properties. Generally, we do not explicitly refer to the corresponding auxiliary projective transformation t concerned, but simply comment that By the

Fundamental Theorem of Projective Geometry, we may choose the four Points . . . (no three of which are collinear) to be the triangle of reference and the unit Point; that is, to have homogeneous coordinates [1,0,0], [0,1,0], [0,0,1] and [1,1,1], respectively.

3. **Pappus' Theorem** Let A, B and C be three points on a line in $\mathbb{R}^2$, and let A , B and C be three points on another line. Let BC and $B\ C$ meet at P, CA and $C\ A$ meet at Q, and AB and $A\ B$ meet at R. Then P, Q and R are collinear.
4. Any Euclidean figure in an embedding plane corresponds to a projective figure in $\mathbb{RP}^2$. It follows that a Euclidean theorem concerned with projective properties (such as collinearity and coincidence) holds if and only if the corresponding projective theorem holds.
5. The **dual** of a statement about the projective properties of some figure in $\mathbb{RP}^2$ is the corresponding statement about $\mathbb{RP}^2$ in which the terms Point and Line are interchanged, and such other changes are made that ensure that the sentence makes sense.

   A triangle (three non-collinear Points and the Lines joining them) is self-dual.
6. A **hexagon** in $\mathbb{RP}^2$ consists of six Points joined by the six Lines joining them in turn.

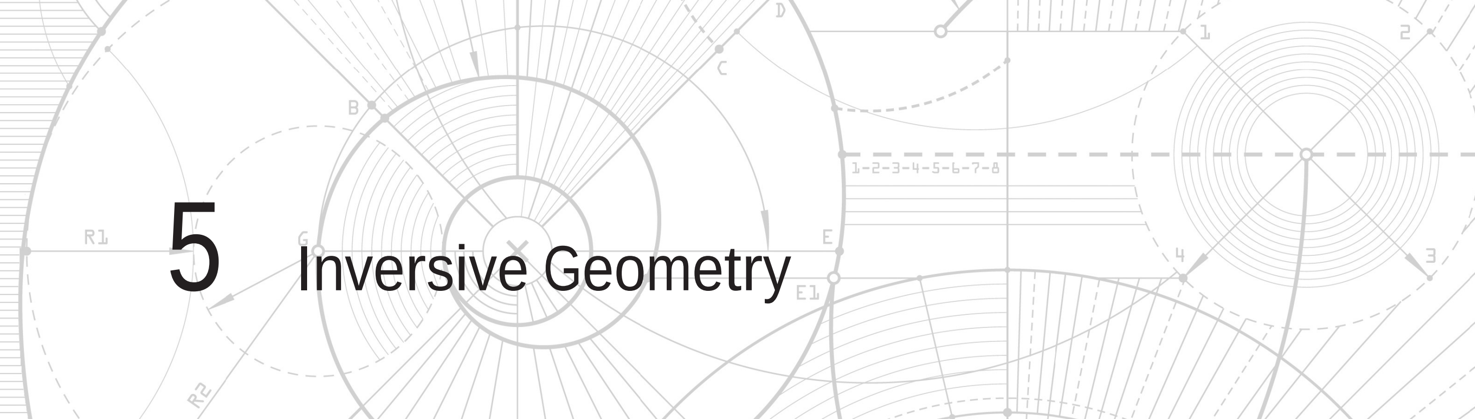
   Pappus' Theorem (rephrased) Let the vertices A, B , C, A , B and C of a hexagon lie alternately on two different Lines. Then the Points of intersection of opposite sides $B\ C$ and BC , CA and $C\ A$, and AB and $A\ B$, are collinear.
7. **Brianchon's Theorem** (the dual of Pappus Theorem) Let the sides AB , $B\ C, CA$, $A\ B, BC$, $C\ A$ of a hexagon pass alternately through two (different) Points P and Q in $\mathbb{RP}^2$. Then the Lines joining opposite vertices A and A , B and B , C and C , are concurrent.
8. **Converse of Desargues' Theorem** (also its dual) Let two triangles be such that the Points through which corresponding sides pass are collinear. Then the Lines through the corresponding vertices of the two triangles are concurrent.

Section 3.5: Cross-Ratio

1. Let A, B, C, D be four collinear Points in $\mathbb{RP}^2$ represented by the position vectors $\mathbf{a}$, $\mathbf{b}$, $\mathbf{c}$, $\mathbf{d}$, and let $\mathbf{c} = \ \mathbf{a} + \ \mathbf{b}$% and $\mathbf{d} = \ \mathbf{a} + \ \mathbf{b}$. Then the **cross-ratio** of A, B, C, D is $(ABCD) = -\ \ -$.

   The cross-ratio $(ABCD)$ is independent of the homogeneous coordinates that are used to represent the collinear Points A, B, C, D.
2. Let A, B, C, D be four distinct collinear Points in $\mathbb{RP}^2$, and let $(ABCD) = k$. Then $(BACD) = (ABDC) = 1\ \ k$ and $(ACBD) = (DBCA) = 1\ \ \ k$.
3. Let t be a projective transformation, and let A, B, C, D be any four collinear Points in $\mathbb{RP}^2$. If $A\ \ = t(A)$, $B\ \ = t(B)$, $C\ \ = t(C)$, $D\ \ = t(D)$, then $(ABCD) = \ A\ B\ C\ D\ \ $.

4. Let A, B, C, D be four distinct Points on a Line, and let $A\ , B\ , C\ , D$ be four distinct Points on another Line such that $AA\ , BB\ , CC\ , DD$ all meet at a Point U. Then $(ABCD) = \ A\ B\ C\ D\ $.
5. **Unique Fourth Point Theorem** Let A, B, C, X, Y be collinear Points in $\mathbb{RP}^2$ such that $(ABCX) = (ABCY)$. Then $X = Y$.
6. Let A, B, C, D and A, E, F, G be two sets of collinear Points (on different Lines in $\mathbb{RP}^2$) such that the cross-ratios $(ABCD)$ and $(AEFG)$ are equal. Then the Lines BE, CF and DG are concurrent.
7. Let four collinear Points of $\mathbb{RP}^2$ pierce an embedding plane at the points A, B, C, D with position vectors **a**, **b**, **c**, **d**, respectively. Then, if we can write **c** and **d** in the form $\mathbf{c} = \ \mathbf{a} + (1 \quad)\,\mathbf{b}$ and $\mathbf{d} = \mu\mathbf{a} + (1 \quad \mu)\,\mathbf{b}$, we have
$$(ABCD) = \frac{1 \qquad}{\qquad} \quad \frac{1 \quad \mu}{\mu} = \frac{AC}{CB} \quad \frac{AD}{DB}.$$
8. **Strategy** To use an embedding plane to calculate the cross-ratio of four collinear Points:
    1. if the four Points pierce the embedding plane at A, B, C, D, then $(ABCD) = \frac{AC}{CB} \% \frac{AD}{DB}$;
    2. if one of the Points is an ideal Point for the embedding plane, then
$$\begin{aligned}(ABCD) &= \frac{DB}{CB} &&\text{if } A \text{ is ideal,}\\ (ABCD) &= \frac{CA}{DA} &&\text{if } B \text{ is ideal,}\\ (ABCD) &= \frac{BD}{AD} &&\text{if } C \text{ is ideal,}\\ (ABCD) &= \frac{AC}{BC} &&\text{if } D \text{ is ideal.}\end{aligned}$$
9. Cross-ratios can be used to measure distances on the ground from aerial photographs, since the cross-ratio of any four points on a line on the ground equals the cross-ratio of their images on the film.



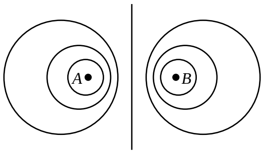
5 Inversive Geometry

In this chapter we introduce a geometry known as *inversive geometry* and use it to investigate circles and lines.

We also prove the *Apollonian Circles Theorem*: namely, that if A and B are two given points in the plane, then all the points P in the plane such that $PA : PB$ is a fixed ratio $k : 1$, for some positive real number $k = 1$, lie on a circle. Notice that if $k = 1$, the locus of points P such that $PA : PB = 1 : 1$ is simply the set of points equidistant from A and B, namely the perpendicular bisector of the segment AB.

This surprising fact was proved by the Greek geometer Apollonius of Perga (2nd century BC).

So for each pair of points A, B there is a family of circles known as the *circles of Apollonius*. Small values of k yield circles close to A, whereas large values yield circles close to B. It is sometimes helpful to regard the points A and B as point circles, corresponding to k being zero and infinity, respectively.



Apollonian circles

The key tool in our work is *inversion*, which is a generalization of the notion of reflection of points in a line. Just as reflection in a line maps points on one side of the line to points on the other, so inversion in a circle maps points inside the circle to points outside, and vice versa.

One difficulty that arises when we tackle problems like the Apollonian Circles Theorem is the presence of a line amongst what would otherwise be a family of circles. Clearly, it would be convenient if we could tackle such problems without having to treat the line as a special case. An ingenious way to do this is to think of the line as a circle of infinite radius in which the ends of the line have been joined by an additional point at infinity. This interpretation enables us to introduce the term *generalized circle* to mean either a line or a circle.

To make the idea of a point at infinity precise, we introduce a space known as the *extended plane*. This consists of the ordinary plane $\mathbb{R}^2$ together with an additional point that we define to be the *point at infinity*. This extended plane is the space in which we study inversive geometry. The transformations of this geometry, known as *inversive transformations*, are defined to be the composites of inversions.

Inversive transformations have the remarkable properties that they preserve the magnitude of angles between intersecting curves, and they map generalized circles onto generalized circles. These properties enable us to use inversive geometry to prove results like the Apollonian Circles Theorem.

In Section 5.1, we define inversion and study its basic properties.

In Section 5.2, we introduce the *extended plane*, and show how certain transformations of this plane can be represented using complex numbers. We then introduce the idea of a *generalized circle*, and show that every inversion preserves the magnitude of angles, and maps generalized circles onto generalized circles. We end the section by giving an interpretation of the extended plane in terms of the so-called *Riemann sphere*. On this sphere all generalized circles actually look like ordinary circles.

In Section 5.3, we formally define what is meant by an *inversive transformation* and *inversive geometry*. The group of all inversive transformations has a subgroup which consists of the so-called *Möbius transformations*. This subgroup is analogous to the subgroup of direct isometries in Euclidean geometry.

In Section 5.4, we prove the *Fundamental Theorem of Inversive Geometry:* namely, that any three points in the extended plane can be mapped onto any other three points by an inversive transformation. We use this result to show that, in inversive geometry, all generalized circles are congruent.

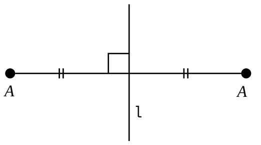
Finally, in Section 5.5 we use inversive geometry to prove the Apollonian Circles Theorem and to study various families of circles.

5.1 Inversion

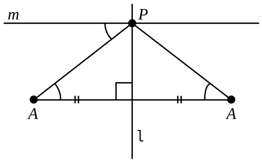
5.1.1 Reflection and Inversion

We begin our exploration of inversive geometry by introducing a type of transformation known as *inversion*. These transformations will be used in Section 5.3 to define inversive geometry.

Roughly speaking, an inversion is a transformation of the plane that generalizes reflection in a line. Instead of mapping points from one side of a line to the other, an inversion maps points inside a circle to points outside the circle, and vice versa.

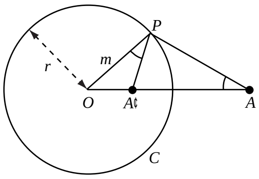


Recall that under reflection in a line ℓ, a point A is mapped to an image point A' that lies an equal distance from ℓ, but on the opposite side of ℓ. In order to generalize this notion of a reflection, we shall reformulate it in a way that provides us with a sensible analogue when the line ℓ is replaced by a circle C.

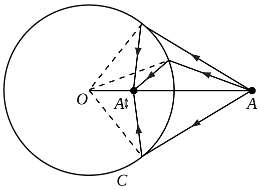


To do this, let m be a line parallel to AA' that crosses ℓ at some point P. Under reflection in ℓ, $\angle PAA'$ maps to $\angle PA'A$, so these two angles must be equal. But since the lines m and AA' are parallel, the angle $\angle PA'A$ is equal to the angle between PA' and m, so $\angle PAA'$ is equal to the angle between PA' and m. This is the clue that we need to generalize reflection.

By a stretch of the imagination, we can think of ℓ as an infinitely large circle with m lying along the radius through P. If we replace ℓ by a circle C of finite radius, and we replace m by a radial line that meets C at some point P, then, by analogy with reflection, we can define the image of A to be the point A' on the line segment OA for which $\angle OPA'$ is equal to $\angle PAO$. We say that A' is the point *inverse to* A *with respect to the circle* C.



Of course, for this definition to work, we must check that for a given point A, the position of the point A' is independent of P. To do this, observe that the triangles $\triangle POA'$ and $\triangle AOP$ are similar, for they have a common angle at O and $\angle OPA' = \angle OAP$. It follows that



$$\frac{OA'}{OP} = \frac{OP}{OA},$$

so

$$OA \cdot OA' = OP^2.$$

But OP is equal to the radius r of C, so

$$OA \cdot OA' = r^2. \tag{1}$$

Since there is only one point A' on the line segment OA that satisfies equation (1), and since the equation does not depend on P, it follows that the position of A' does not depend on the choice of P.

Although the above construction illustrates how inversion can be defined as a generalization of reflection, it is worth noting that equation (1) is all that we need to determine the point A' that corresponds to a given point A. For simplicity, we shall therefore use equation (1) as our formal definition of inversion.

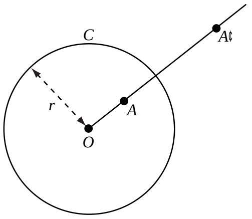
Definitions Let C be a circle with centre O and radius r, and let A be any point other than O. If A' is the point on the line OA that lies on the same side of O as A and satisfies the equation

$$OA \cdot OA' = r^2, \tag{2}$$

then we call A' the **inverse** of A with respect to the circle C. The point O is called the **centre of inversion**, and C is called the **circle of inversion**. The transformation t defined by

$$t(A) = A' \quad A \in \mathbb{R}^2 - \{O\}$$

is known as **inversion in** C.



$OA \cdot OA' = r^2$

Remark

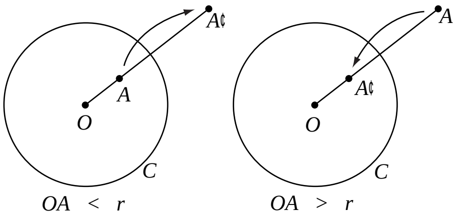
Since $OA \cdot OA' = r^2$ is non-zero, neither OA nor OA' can be zero, and so neither A nor A' can coincide with O. It is for this reason that O is excluded from the domain of the transformation t since there is no point to which O can be mapped. Likewise, there is no point that maps *to* O.

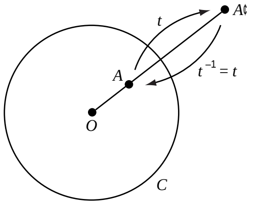
We can sometimes write down the inverse of a point directly from the above definition. For example, if C is the unit circle $\left\{(x,y) : x^2 + y^2 = 1\right\}$, then the inverse of (0, 2) with respect to C is the point $\left(0, \frac{1}{2}\right)$, and the inverse of $\left(-\frac{1}{3}, 0\right)$ is the point $(-3, 0)$.

Problem 1 Write down the inverse of each of the following points with respect to the circle of unit radius, centred at the origin.

(a) (4, 0) (b) (0, 1) (c) $\left(0, -\frac{1}{3}\right)$ (d) $\left(\frac{1}{4}, 0\right)$

Inversion distorts the plane considerably, for it maps points inside a circle C to points outside C, and vice versa. Indeed, if $OA < r$, then $OA' = r^2/OA > r$, whereas, if $OA > r$, then $OA' = r^2/OA < r$. Any point that lies on C maps to itself.



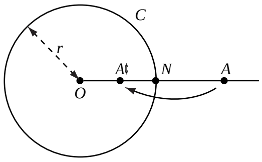


Note that if A' is the inverse of A, then A must be the inverse of A', for if $OA \cdot OA' = r^2$ then clearly $OA' \cdot OA = r^2$; we say that A and A' are **inverse points** with respect to C. In this sense, inversion is like reflection; if we reflect a point in a line and then reflect the reflection, we obtain the original point back again. Any transformation t that has this property is said to be *self-inverse* because it shows that t^{-1} exists and is equal to t.

Theorem 1 Inversion in a circle is a self-inverse transformation.

Since any transformation that has an inverse is one–one, it follows that every inversion is a one–one transformation. Remember, however, that since O is excluded from its domain, an inversion is a one–one transformation of $\mathbb{R}^2 - \{O\}$ onto itself.

Earlier, we mentioned that inversion can be regarded as a generalization of reflection. To see how this follows from the definition of inversion, we examine what happens to the inverse of a point A as we increase the radius of the circle.

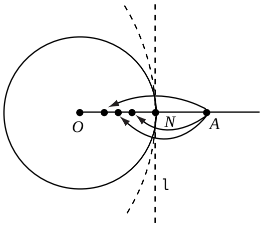


Let A be a point outside a circle C with centre O and radius r, let A' be the inverse of A with respect to C, and let the line segment AA' meet the circle at N. Then $OA = r + AN$ and $OA' = r - A'N$, so the equation $OA \cdot OA' = r^2$ becomes

$$(r + AN)(r - A'N) = r^2.$$

After expanding the brackets, cancelling the r^2 terms, and solving for $A'N$, we obtain

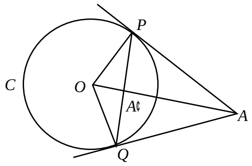
$$A'N = \frac{AN \bullet r}{r + AN} = \frac{AN}{1 + AN/r}.$$



Now fix A and N, and let the radius r of the circle tend to infinity. As it does so, it follows from the above equation that the length of $A'N$ tends to the length of AN. In other words, reflection in a line can be regarded as the limiting case of inversion in circles of increasing radii. For this reason, we adopt the following useful convention.

Convention We use the term **inversion** to mean either reflection in a line or inversion in a circle.

The following gives a geometric method for constructing inverse points with respect to a given circle.



Let A be a point outside a circle C with centre O and radius r, let AP and AQ be the two tangents from A to C, and let A' be the point of intersection of OA and PQ. Then A and A' are inverse with respect to C.

For, in the triangles $\triangle OPA'$ and $\triangle OAP$, the angles at O are equal and the two angles $\angle OA'P$ and $\angle OPA$ are equal, since they are both right angles; hence all the angles in the two triangles are equal. Thus the triangles are similar; hence, in particular, we must have that

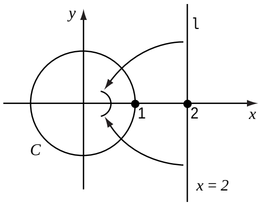
$$\frac{OA}{OP} = \frac{OP}{OA'},$$

so that

$$OA \bullet OA' = OP^2 = r^2.$$

Thus A and A' are inverse with respect to C, as claimed.

We end this subsection by showing that an inversion in a circle is a different type of transformation from those that arise in Euclidean and affine geometry.



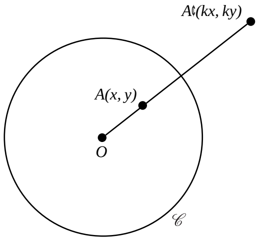
First, an inversion in a circle is not an affine transformation since it does not map lines to lines. For example, let C be the unit circle and ℓ be the line with equation $x = 2$. All the points on ℓ lie outside the unit circle, and so inversion in C must map all the points of ℓ to points that lie inside the unit circle. In particular, the image of ℓ cannot be a line. Thus, since the image of a line under any affine transformation is itself a line, it follows that inversion cannot be an affine transformation.

An inversion in a circle is not a Euclidean transformation either, for like affine transformations, Euclidean transformations map lines to lines. Indeed, a Euclidean transformation is just a special type of affine transformation.

5.1.2 The Effect of Inversion on Lines and Circles

In the previous subsection you saw how to construct the point A' that is the inverse of a given point A with respect to a given circle C. However, in order to study many of the properties of inversion, we require an *algebraic* formula that relates the coordinates of A and A'.

For our present purposes it is sufficient to derive the formula for the case where $\mathscr{C}$ is the unit circle $\{(x, y) : x^2 + y^2 = 1\}$. This circle will occur so frequently in our work that we denote it by the special symbol C.



Let A be a point $(x, y) \in \mathbb{R}^2 - \{O\}$, and let A' be its image under inversion in the unit circle C. Since A' lies on the same half-line from the origin as does A, it follows that A' must have coordinates (kx, ky), for some positive number k.

Since the radius of C is 1, we must have $OA \cdot OA' = 1$. Thus $OA^2 \cdot OA'^2 = 1$, and so

$$\left(x^2 + y^2\right)\left(k^2x^2 + k^2y^2\right) = 1.$$

It follows that

$$k^2 = \frac{1}{\left(x^2 + y^2\right)^2},$$

and hence that

$$k = \frac{1}{x^2 + y^2}.$$

Thus A' is the point $\left(\frac{x}{x^2+y^2}, \frac{y}{x^2+y^2}\right)$. We therefore have the following algebraic description of inversion in the unit circle.

Theorem 2 Inversion in the unit circle C is the function

$$t : (x, y) \mapsto \left(\frac{x}{x^2 + y^2}, \frac{y}{x^2 + y^2}\right) \quad \left((x, y) \in \mathbb{R}^2 - \{O\}\right).$$

We may use this theorem to find the image of any non-zero point of $\mathbb{R}^2$ under inversion in the unit circle C. For example, the image of $(3, -2)$ is the point

$$\left(\frac{3}{3^2 + (-2)^2}, \frac{-2}{3^2 + (-2)^2}\right) = \left(\tfrac{3}{13}, -\tfrac{2}{13}\right).$$

Problem 2 Determine the image of each of the following points under inversion in C.

(a) (4,1) (b) $\left(\frac{1}{2}, -\frac{1}{4}\right)$

Now let (x', y') be the image of (x, y) under inversion in C. Since inversion is self-inverse, it follows that

$$(x, y) = \left(\frac{x'}{(x')^2 + (y')^2}, \frac{y'}{(x')^2 + (y')^2}\right).$$

Using this relationship between (x, y) and (x', y'), we can find the image of a curve under inversion in $\mathscr{C}$ in much the same way as we found the image of a curve in affine geometry. The main difference is that we must be careful to remember that inversion is not defined at the origin (the centre of inversion) and that no point is mapped to the origin.

We shall return to the question of what happens at the origin later, in Subsection 5.2.3.

Example 1 Determine the image under inversion in $\mathscr{C}$ of the line $2x + 4y = 1$.

Solution Let (x, y) be an arbitrary point on the line $2x + 4y = 1$, and let (x', y') be the image of (x, y) under inversion in $\mathscr{C}$. Then

$$(x, y) = \left(\frac{x'}{(x')^2 + (y')^2}, \frac{y'}{(x')^2 + (y')^2}\right).$$

Since x and y are related by the equation $2x + 4y = 1$, it follows that x' and y' are related by the equation

$$\frac{2x'}{(x')^2 + (y')^2} + \frac{4y'}{(x')^2 + (y')^2} = 1.$$

Multiplying by $(x')^2 + (y')^2$, we obtain $2x' + 4y' = (x')^2 + (y')^2$, and by completing the square we may write this as

$$(x' - 1)^2 + (y' - 2)^2 = 5.$$

Dropping the dashes, we see that points on the image must have (x, y)-coordinates which satisfy the equation

$$(x - 1)^2 + (y - 2)^2 = 5.$$

This is the equation of a circle with centre (1, 2) and radius $\sqrt{5}$. Since this passes through the origin, and since the origin cannot be part of the image under the inversion, the required image must be the circle with the origin removed. □

For every point on $(x - 1)^2 + (y - 1)^2 = 5$ other than (0, 0) is the image of some point on $2x + 4y = 1$.

In this example we used dashes to distinguish the coordinates of a point (x, y) from the coordinates of its image (x', y'). However, once you have understood the method you may prefer to adopt the strategy below. This uses the same method as in the example, but it drops the dashes throughout.

Strategy To determine an equation for the image of a curve under inversion in the unit circle $\mathscr{C}$:

1. write down an equation that relates the x- and y-coordinates of points on the curve;
2. replace x by $\frac{x}{x^2+y^2}$ and y by $\frac{y}{x^2+y^2}$, and simplify the resulting equation.

When using this strategy to find the image of a curve that passes through the origin, we must first remove the origin from the curve.

We may also have to exclude the origin from the image.

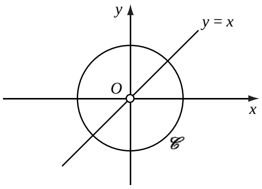
Example 2 Determine the image under inversion in C of the line $y = x$ (with the origin removed).

Solution Replacing x by $\frac{x}{x^2+y^2}$ and y by $\frac{y}{x^2+y^2}$, we obtain

$$\frac{y}{x^2 + y^2} = \frac{x}{x^2 + y^2}.$$

Hence

$$y = x.$$



This is the line we started with. Just as the origin had to be excluded from that line before we could find its image, so the origin has to be excluded from the image. Hence the line $y = x$ (with the origin removed) maps to itself under inversion in C. □

We shall use the term **punctured** to describe a line or circle that has one of its points removed. More specifically, if A is the point removed from a line or circle, then the line or circle is said to be **punctured at** A.

Problem 3 Determine the image under inversion in C of the line $y = 2x$ punctured at the origin.

Problem 4 Let be the line with equation $x + y = 1$.

(a) Determine the image of under inversion in C.
(b) Explain why the points (1, 0), (0, 1) lie both on and on its image.
(c) Sketch and its image on a single diagram.

The solutions to these problems and the preceding examples illustrate the following general result.

Theorem 3 Images of Lines under Inversion
Under inversion in a circle with centre O:

(a) a line that does not pass through O maps onto a circle punctured at O;
(b) a line punctured at O maps onto itself.

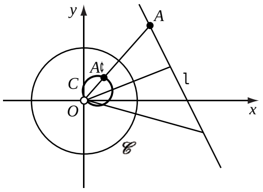
Proof First choose a pair of coordinate axes with origin at O, and choose a unit of length equal to the radius of the circle in which we are inverting. Then the circle in which we are inverting becomes the unit circle C.

(a) If is a line that does not pass through the origin, then it has an equation of the form

$$ax + by + c = 0,$$

where c is non-zero. Using the above strategy, we know that the image of ℓ under inversion in $\mathscr{C}$ has equation

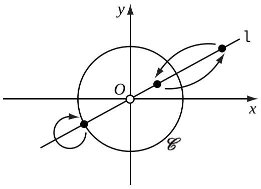
$$\frac{ax}{x^2+y^2} + \frac{by}{x^2+y^2} + c = 0.$$



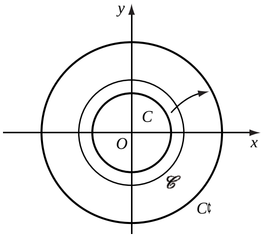
Since c is non-zero, we may rewrite this in the form

$$x^2 + y^2 + (a/c)x + (b/c)y = 0.$$

This is the equation of a circle C through the origin. If the origin is removed from this circle, then each remaining point A' is the image of the point A at which OA' intersects ℓ. It follows that the image of ℓ is the whole of the punctured circle $C - \{O\}$.



(b) Although we could use the strategy to prove this part as well, it is easier to work directly from the definition of inversion. Indeed, if ℓ is a line punctured at O, then each point of ℓ inside $\mathscr{C}$ is the image of a point of ℓ outside $\mathscr{C}$, and each point of ℓ outside $\mathscr{C}$ is the image of a point of ℓ inside $\mathscr{C}$. Points of ℓ that lie on $\mathscr{C}$ map to themselves. It follows that the punctured line ℓ maps onto itself, as required.



Next, we consider the images of circles under inversion. Since points on the circle of inversion map to themselves, the image of that circle is also a circle. Also, any circle C with centre the centre of inversion O must map onto another circle C' with centre O, for, by symmetry, every point of C is mapped an equal distance along a radial line.

This raises the question as to whether an inversion always maps circles to circles.

Example 3 Use the above strategy to determine the image under inversion in $\mathscr{C}$ of the circle C with centre (2, 0) and radius 1.

Solution The circle C has equation $(x-2)^2+y^2=1$, which we may rewrite in the form

$$x^2+y^2-4x+3=0.$$

Using the above strategy, we deduce that the image of C under inversion in $\mathscr{C}$ has equation

Note that the origin does not lie on C.

$$\left(\frac{x}{x^2+y^2}\right)^2 + \left(\frac{y}{x^2+y^2}\right)^2 - \frac{4x}{x^2+y^2} + 3 = 0.$$

We may add together the first two terms of this equation to obtain

$$\frac{1}{x^2+y^2} - \frac{4x}{x^2+y^2} + 3 = 0,$$

which we may rearrange in the form

$$x^2 + y^2 - \tfrac{4}{3}x + \tfrac{1}{3} = 0.$$

By completing the square we obtain

$$\left(x - \tfrac{2}{3}\right)^2 + y^2 = \left(\tfrac{1}{3}\right)^2.$$

This is the equation of a circle with centre $\left(\tfrac{2}{3}, 0\right)$ and radius $\tfrac{1}{3}$. □

So in this example the circle C does indeed map to another circle. Notice, however, that the centre (2, 0) of C maps to $(\tfrac{1}{2}, 0)$ which is *not* the centre of the image of C. It follows that even if an inversion maps one circle onto another, it may not map the centres to each other.

Problem 5 Determine the image under inversion in $\mathscr{C}$ of the circle with centre (2, 2) and radius 1.

The next example illustrates what happens when we use the strategy to find the image of a circle that passes through the origin.

Example 4 Let C be the circle with centre $(-2, 0)$ and radius 2, punctured at the origin. Determine the image of C under inversion in $\mathscr{C}$.

Solution The circle C has equation $(x + 2)^2 + y^2 = 2^2$, which we may rewrite in the form

$$x^2 + y^2 + 4x = 0.$$

Using the above strategy, we deduce that the image of C under inversion in $\mathscr{C}$ has equation

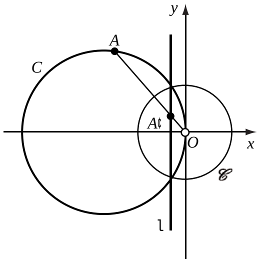
$$\left(\frac{x}{x^2 + y^2}\right)^2 + \left(\frac{y}{x^2 + y^2}\right)^2 + \frac{4x}{x^2 + y^2} = 0.$$

Adding together the first two terms of this equation, we obtain

$$\frac{1}{x^2 + y^2} + \frac{4x}{x^2 + y^2} = 0,$$

which we may rearrange in the form $1 + 4x = 0$.

It follows that the image of the punctured circle C is the line ℓ with equation $x = -\tfrac{1}{4}$. From the figure in the margin it is clear that every point of ℓ is the image of some point on C, so there is no need to puncture ℓ. □



Problem 6 Let C be the circle with centre $\left(0, -\tfrac{1}{4}\right)$ and radius $\tfrac{1}{4}$, punctured at the origin. Determine the image of C under inversion in $\mathscr{C}$.

The conclusions of Examples 3 and 4, and of Problems 5 and 6, suggest the following result.

Theorem 4 Images of Circles under Inversion
Under inversion in a circle with centre O:

(a) a circle that does not pass through O maps onto a circle;
(b) a circle punctured at O maps onto a line that does not pass through O.

Proof As for Theorem 3, we choose a pair of coordinate axes that makes the circle in which we are inverting the unit circle $\mathcal{C}$.

Now let C be an arbitrary circle with centre (a, b) and radius r. This has equation

$$(x - a)^2 + (y - b)^2 = r^2,$$

which we may rewrite in the form

$$x^2 + y^2 - 2ax - 2by + c = 0,$$

Note that this passes through O if and only if $c = 0$.

where $c = a^2 + b^2 - r^2$. Using the strategy for determining the images of curves under inversion, we deduce that the image of C under inversion has equation

$$\left(\frac{x}{x^2+y^2}\right)^2 + \left(\frac{y}{x^2+y^2}\right)^2 - \frac{2ax}{x^2+y^2} - \frac{2by}{x^2+y^2} + c = 0.$$

Adding together the first two terms of this equation, we obtain

$$\frac{1}{x^2+y^2} - \frac{2ax}{x^2+y^2} - \frac{2by}{x^2+y^2} + c = 0.$$

By multiplying this equation by $\left(x^2 + y^2\right)$, we may rearrange it in the form

$$1 - 2ax - 2by + c\left(x^2 + y^2\right) = 0. \qquad (3)$$

This is the equation of either a line or a circle, depending on whether or not C passes through O.

(a) If C does not pass through O, then c is non-zero. We can therefore divide equation (3) by c to obtain

$$x^2 + y^2 - 2\tfrac{a}{c}x - 2\tfrac{b}{c}y + \tfrac{1}{c} = 0.$$

This is the equation of a circle on which the image of C must lie.

(b) If C does pass through O, then $c = 0$, so equation (3) becomes

$$1 \quad 2ax \quad 2by = 0.$$

This is the equation of a line that does not pass through O.

The following box summaries the results of Theorem 3 and 4.

Under inversion with respect to a circle with centre O:

a line punctured at O	*maps onto*	the same line punctured at O;
a line not through O	*maps onto*	a circle punctured at O;
a circle punctured at O	*maps onto*	a line not through O;
a circle not through O	*maps onto*	a circle not through O.

If the circle of inversion is the unit circle C, then O is the origin.

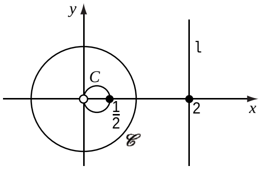
There is no need to remember the details of this summary since its predictions can be recalled intuitively as follows. First, points on a line or circle through the origin can be chosen arbitrarily close to the origin. The images of such points can therefore be chosen arbitrarily far from the origin, and must therefore lie on a line. Secondly, points on a line can be chosen arbitrarily far from the origin. The images of these points can be chosen arbitrarily close to the origin and must therefore lie on a circle or line punctured at the origin.

With a little practice it is easy to use the summary to simplify the work needed to determine the image of a circle or line under an inversion.

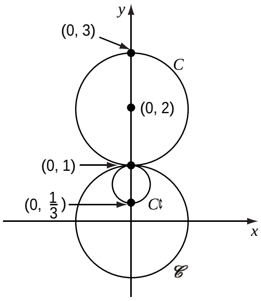
Example 5 Determine the image of each of the following under inversion in the unit circle C:

(a) the line with equation $x = 2$;
(b) the circle C with centre (0, 2) and radius 1.

Solution



(a) From the summary, we know that maps to a circle C punctured at the origin. This circle passes through the point $\frac{1}{2}, 0$, since $\frac{1}{2}, 0$ is the image of the point (2, 0) on the line. Since is symmetrical about the x-axis, it follows that the image circle must also be symmetrical about the x-axis. The only circle C that fulfils all these criteria is the circle with radius $\frac{1}{4}$ and centre $\frac{1}{4}, 0$.



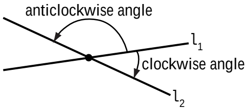
(b) From the summary, the image C of C is a circle that does not pass through the origin. It must be symmetrical about the y-axis (because C is), and it must pass through the points $0, \frac{1}{3}$ and (0, 1) (the images of (0, 3) and (0, 1), respectively). The only circle C that fulfils all these criteria is the circle with radius $\frac{1}{3}$ and centre $0, \frac{2}{3}$. □

Problem 7 Determine the image of each of the following under inversion in the unit circle $\mathcal{C}$:

(a) the line ℓ with equation $y = 1$;
(b) the circle C with centre (0, 1) and radius 1 (punctured at the origin).

5.1.3 The Effect of Inversion on Angles

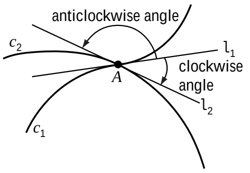
In this subsection we shall show that inversion preserves the magnitude of the angle at which two curves meet. First, however, we must clarify what it means to measure the angle between two intersecting curves.



In the case of two intersecting lines ℓ_1 and ℓ_2 there are two ways in which we can measure the angle from ℓ_1 to ℓ_2. We can measure it either in a clockwise direction, or in an anticlockwise direction, as shown in the margin. Clearly, the magnitude of the angle depends on the direction we choose, so when specifying an angle we must give both its magnitude and direction.

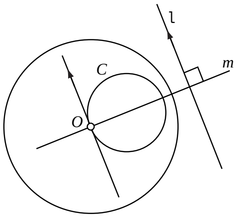
In the case of two intersecting *curves*, we define the angle between the curves by using tangents, as follows.

Definitions Let c_1 and c_2 be two curves that intersect at the point A, and let the tangents to the curves at A be ℓ_1 and ℓ_2, respectively. Then the **anticlockwise angle** from c_1 to c_2 at A is the anticlockwise angle from ℓ_1 to ℓ_2, and the **clockwise angle** from c_1 to c_2 at A is the clockwise angle from ℓ_1 to ℓ_2.



To examine what happens to the angles between two curves under an inversion, it is sufficient to examine what happens to the angles between the corresponding tangents.

For the moment let us concentrate on what happens to a single line ℓ under inversion in a circle centred at O. We know that ℓ maps onto a circle C punctured at O. But we can say more, for if m is the line through O that is perpendicular to ℓ, then ℓ is symmetrical about m. It follows that the circle C is symmetrical about m, and so ℓ is parallel to the tangent to C at O. We state this result as the Symmetry Lemma.

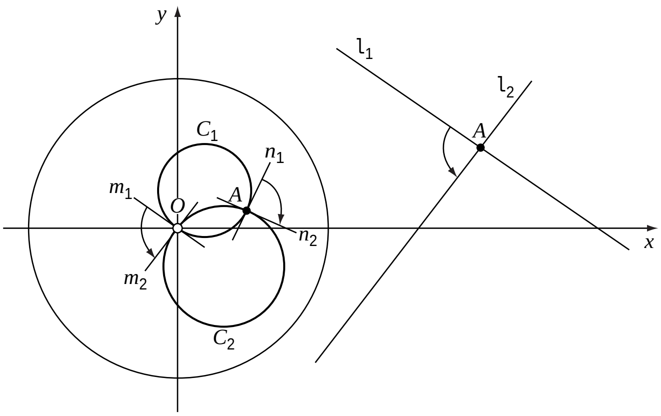


Lemma 1 Symmetry Lemma
Let ℓ be a line that does not pass through the point O. Then under inversion in a circle with centre O, ℓ maps to a circle C (punctured at O), and the tangent to C at O is parallel to ℓ.

Now consider what happens to the angle between two lines ℓ_1 and ℓ_2 which intersect at some point A other than O, as shown below. For the moment we shall assume that neither line passes through O, so that under the inversion the lines map to punctured circles C_1 and C_2, respectively. These punctured circles meet at the point A', where A' is the image of A. We want to compare

We ask you to investigate what happens when one of the lines passes through O in Problem 8.

the angle from ℓ_1 to ℓ_2 at A' with the angle from C_1 to C_2 at A. The trick we use is to compare both angles with the angle from C_1 to C_2 at O.



By the Symmetry Lemma, ℓ_1 is parallel to the tangent m_1 to C_1 at O, and ℓ_2 is parallel to the tangent m_2 to C_2 at O. It follows that the angle from ℓ_1 to ℓ_2 must be equal in magnitude and direction to the angle we have shown from m_1 to m_2.

Next observe that the reflection in the line through the centres of C_1 and C_2 sends the tangents m_1, m_2 at O to the tangents n_1, n_2 at A. Since the reflection preserves the magnitude of an angle but changes its orientation, we conclude that the angle from n_1 to n_2 at A must be equal in magnitude but *opposite* in orientation to the angle from m_1 to m_2 at O.

Overall, we have shown that the angle from C_1 to C_2 at A must be equal in magnitude but opposite in orientation to the angle from ℓ_1 to ℓ_2 at A'.

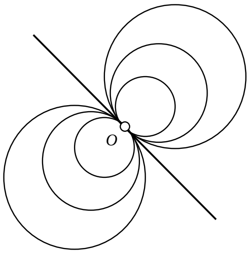
We sometimes abbreviate this by saying that the angle at A' is *equal but opposite* to the angle at A.

Theorem 5 Angle Theorem
An inversion in any circle preserves the magnitude of angles between curves but reverses their orientation.

The next problem asks you to complete our proof of this theorem.

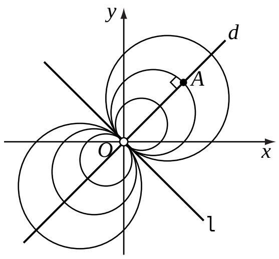
Problem 8 Prove the Angle Theorem in the case where one of the lines passes through the centre of inversion.

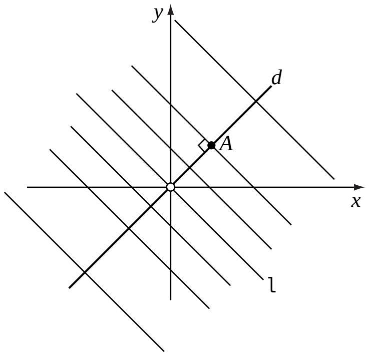
The Angle Theorem provides us with a very powerful tool for locating the images of two or more circles or lines under inversion.



Example 6 A family of circles shares a common tangent at the origin O, as shown in the margin. Describe the effect of inverting the family of circles (all punctured at O) in the unit circle C. Illustrate your answer with a sketch.

Solution Let be the common tangent to the circles, as shown on the left below. If d is the punctured line through O perpendicular to , then each of the circles crosses d at right angles. Since all the circles are punctured at O, their images under the inversion must be straight lines, as shown on the right. By the Angle Theorem, these straight lines must cross the image of d at right angles. But d maps onto itself under the inversion, so the punctured circles map to a family of parallel lines perpendicular to d.

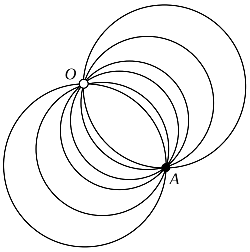




In fact, apart from , every line perpendicular to d must be the image of a punctured circle in the family. For if a perpendicular line meets d at some point A , then it must be the image of the punctured circle that passes through the point A which is mapped to A under the inversion. □

Problem 9 One family of circles touches the x-axis at the origin O, and another family of circles touches the y-axis at O. Describe the effect of inverting the two families of circles (all punctured at O) in the unit circle C. Illustrate your answer with a sketch.

Problem 10 A family of circles intersects at the origin O and at another point A, as shown in the margin. Describe the effect of inverting the family of circles (all punctured at O) in the unit circle C. Illustrate your answer with a sketch.



Problem 11 Let C_1, C_2 and C_3 be circles in the plane such that C_1 and C_2 touch at the origin O, C_3 and C_1 touch at another point A, and C_2 and C_3 touch at the further point B. Describe the effect of inverting the circles C_1, C_2 (both punctured at O) and C_3 in the unit circle C. Illustrate your answer with a sketch.

These problems illustrate that, by carefully choosing centres of inversion, we can transform some of the circles in a figure to straight lines. Since straight lines are often easier to deal with than are circles, we can use such transformed figures to investigate those properties of the original figures that are preserved by inversions. In essence, this is the idea that underlies inversive geometry, and you will see several example of its use in Section 5.5.

5.2 Extending the Plane

In order to define a geometry in which we can study the properties of circles, lines and angles, we need a group of transformations that preserve these properties. Among the transformations that do this are the Euclidean transformations, and the inversions introduced in the previous section. In this section we describe how such transformations can be represented in terms of complex numbers. This will enable us to manipulate the transformations by using the algebra of complex numbers.

5.2.1 Transformations of the Complex Plane

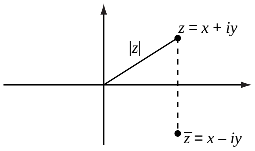
We begin by reminding you of some facts concerning complex numbers.

First, there is a one one correspondence between points (x, y) in the plane $\mathbb{R}^2$ and complex numbers $z = x + iy$ in the complex plane $\mathbb{C}$; we call x and y the **real part** and the **imaginary part** of the complex number z, and denote them by the symbols Re z and Im z, respectively. All the arithmetic operations may be carried out in $\mathbb{C}$ as for real numbers, except that we replace i^2 by 1 wherever i^2 occurs.

Recall that $x + iy$ is the *Cartesian* form of the complex number.

If z is the complex number $x + iy$, then its **conjugate** $\bar{z}$ is defined by

$$\bar{z} = x \quad iy,$$



and its **modulus** $|z|$ is defined by

$$|z| = \sqrt{x^2 + y^2}.$$

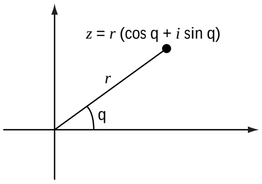
Recall that $|z|^2 = z\bar{z}$.

Problem 1 Let $z_1 = 2 \quad 3i$ and $z_2 = \quad 3 + 4i$.

(a) Determine each of the following complex numbers in Cartesian form.

(i) $z_1 + z_2$ (ii) $z_1 \quad z_2$ (iii) $z_1 z_2$
(iv) z_1 / z_2 (v) $\overline{z_1}$ (vi) $\overline{z_2}$

(b) Determine $|z_1|$ and $|z_2|$.



If a non-zero complex number $z = x + iy$ has modulus r, and if the position vector of the point (x, y) lies at an angle to the positive x-axis, then we can express z in the form

$$r(\cos \quad + i \sin \quad).$$

Such an expression is known as a **polar form** of z, and the angle θ is known as an **argument** of z, written $\arg z$. Polar forms and arguments are not unique, since the same z could equally well be expressed in the form

$$r(\cos(\theta + 2\pi n) + i\sin(\theta + 2\pi n))$$

for any integer n. The **principal argument** of z, written $\operatorname{Arg} z$, is the unique value of $\arg z$ that lies in the interval $(-\pi, \pi]$.

We can obtain the Cartesian form of a complex number from any of its polar forms by using the equations

$$x = r\cos\theta \quad \text{and} \quad y = r\sin\theta,$$

and we can obtain a polar form of a complex number from its Cartesian form by using the equations

$$r = \sqrt{x^2 + y^2}, \quad \cos\theta = \frac{x}{r} \quad \text{and} \quad \sin\theta = \frac{y}{r}.$$

Problem 2 Determine the polar forms of the complex numbers $z_1 = 1 - i$ and $z_2 = -\sqrt{3} + i$ in terms of their principal arguments.

The following strategy can be used to multiply and divide complex numbers given in polar form.

Strategy To multiply two complex numbers given in polar form, multiply their moduli and add their arguments.

To divide two complex numbers given in polar form, divide their moduli and subtract their arguments.

Although this strategy gives an argument for a product or quotient, you may require the principal argument, in which case you will need to adjust the argument by adding an appropriate multiple of 2π.

Problem 3 Let $z_1 = 1 - i$ and $z_2 = -\sqrt{3} + i$. Determine the polar forms of the following complex numbers in terms of their principal arguments.

(a) $z_1 z_2$ (b) z_1/z_2

We can now use the algebra of complex numbers described above to represent some of the basic Euclidean transformations of the plane.

Translations

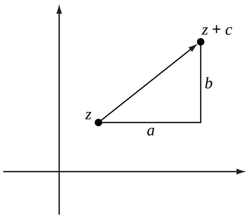
First, consider the transformation

$$t(z) = z + c \quad (z \in \mathbb{C}), \tag{1}$$

where $c = a + ib$. This maps an arbitrary point $x + iy \in \mathbb{C}$ to the point

$$(x + a) + i(y + b),$$

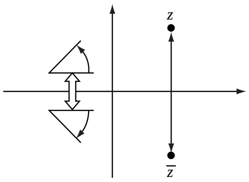
and therefore corresponds to a translation through the vector (a, b). Clearly, such transformations preserve angles, and map circles and lines to circles and lines.



Reflection in the x-Axis

Next, consider the transformation

$$t(z) = \bar{z} \quad (z \in \mathbb{C}). \tag{2}$$

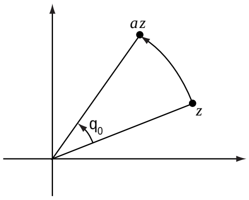


This maps an arbitrary point $x + iy \in \mathbb{C}$ to the point $x - iy$, and therefore corresponds to a *reflection* in the x-axis. It maps circles and lines to circles and lines, and it preserves the magnitude of angles; however, the orientation of angles is reversed.

Rotation about the Origin

Now, consider the transformation

$$t(z) = az \quad (z \in \mathbb{C}), \tag{3}$$



where $|a| = 1$. Since $|a| = 1$ we can write $a = \cos\theta_0 + i\sin\theta_0$, where $\theta_0 = \operatorname{Arg} a$. From the above strategy, t maps an arbitrary point $r(\cos\theta + i\sin\theta)$ in $\mathbb{C}$ to the point

$$r(\cos(\theta + \theta_0) + i\sin(\theta + \theta_0)),$$

and therefore corresponds to a rotation through the angle $\theta_0 = \operatorname{Arg} a$ about the origin. The rotation is clockwise if $\operatorname{Arg} a < 0$ and anticlockwise if $\operatorname{Arg} a > 0$.

Arbitrary Isometries

All the other isometries can be represented in the complex plane as composites of the basic transformations described above. In fact, we have the following result.

Theorem 1 Each isometry t of the plane can be represented in the complex plane by one of the functions

$$t(z) = az + b \quad \text{or} \quad t(z) = a\bar{z} + b,$$

where $a, b \in \mathbb{C}$, $|a| = 1$. Conversely, all such functions represent isometries.

Proof The converse is easy to prove, because every function of the type described is a composite of the basic isometries described above.

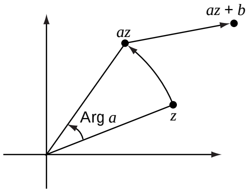
So let t be an isometry of the complex plane, and let $t(0) = b$, $t(1) = c$. If we denote $c - b$ by a, then $|a|$ is the distance between $t(0)$ and $t(1)$, and since t is an isometry it follows that $|a| = 1$. Now let s be the isometry defined by $s(z) = az + b$; then

$$s(0) = b = t(0) \quad \text{and} \quad s(1) = a + b = c = t(1).$$

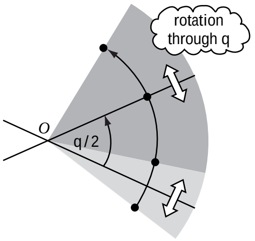
Thus $s^{-1} \circ t$ is an isometry that fixes 0 and 1, and so, since it is an isometry, it must fix each point of the x-axis.

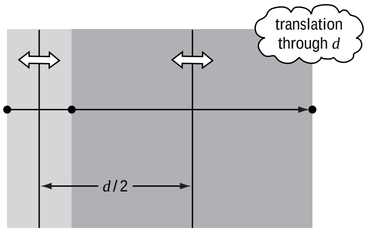
Then using the fact that $s^{-1} \circ t$ is an isometry (that is, it does not alter distances) that leaves each point of the x-axis unaltered, we may deduce that $s^{-1} \circ t$ is EITHER the identity transformation OR a reflection in the x-axis. If it is the identity, then $s^{-1} \circ t(z) = z$, in which case $t(z) = s(z) = az + b$. If it is a reflection, then $s^{-1} \circ t(z) = \bar{z}$, in which case $t(z) = s(\bar{z}) = a\bar{z} + b$.

Theorem 1 may be interpreted as saying that every isometry of the complex plane can be obtained as a rotation (through an angle Arg a) followed by a translation (through the vector (Re b, Im b)), possibly all preceded by a reflection in the real axis.



Slightly more surprising is the fact that every isometry of the plane can be expressed as a composite of reflections alone. This is because each rotation and each translation can be expressed as a composite of two reflections.





Thus a rotation about a point O can be expressed as a reflection in any line through O followed by a reflection in a second line through O, where the angle from the first line to the second line is half the desired angle rotation.

Similarly, a translation can be expressed as a reflection in any line perpendicular to the direction of the translation followed by a reflection in a second line that is parallel to the first and in the direction of the translation relative to the first line. The distance between the lines is half the distance of the translation.

So we have the following result.

Theorem 2 Every isometry can be expressed as a composite of reflections.

Example 1 Let t be the isometry defined by

$$t(z) = i\bar{z} + 4 + 2i \quad (z \in \mathbb{C}).$$

(a) Show that t represents an isometry.
(b) Interpret t as the composite of a reflection, a rotation and a translation.
(c) Interpret t as a composite of reflections.

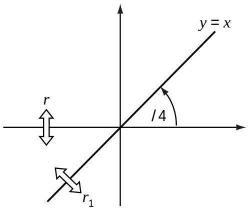
Solution

(a) The coefficient of $\bar{z}$ is i, which has modulus $|i| = 1$. By Theorem 1, it follows that t is an isometry.

(b) In the formula that defines t, the conjugation corresponds to a reflection in the x-axis, the multiplication by i corresponds to an anticlockwise rotation through $\pi/2$, and the addition of $4+2i$ corresponds to a translation through the vector (4, 2).

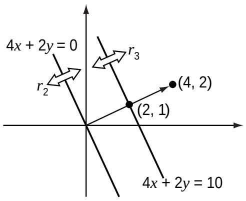
(c) First, let r be the reflection in the x-axis that corresponds to the conjugation.

Next, observe that the anticlockwise rotation through $\pi/2$ can be interpreted as the composite $r_1 \circ r$, where r is the reflection in the x-axis again, and r_1 is the reflection in the line $y = x$ through the origin that makes an angle $\pi/4$ with the x-axis.



Finally, observe that the translation through the vector (4, 2) can be interpreted as the composite $r_3 \circ r_2$, where r_2 is the reflection in the line $4x + 2y = 0$ through the origin that is perpendicular to the vector (4, 2), and r_3 is the reflection in the parallel line $4x + 2y = 10$ that passes through $\frac{1}{2}(4,2) = (2,1)$.

Overall, we have $t = r_3 \circ r_2 \circ r_1 \circ r \circ r$ or, since r is its own inverse, $t = r_3 \circ r_2 \circ r_1$. □



The decompositions illustrated above generalize as follows.

Problem 4 Let t be the transformation defined by

$$t(z) = -i\bar{z} + 6 - 4i \quad (z \in \mathbb{C}).$$

(a) Show that t represents an isometry.
(b) Interpret t as the composite of a rotation and a translation.
(c) Interpret t as a composite of reflections.
Hint: Use the decompositions described in the margin.

To *rotate* the plane $\mathbb{R}^2$ through an angle θ: first reflect in the line $\{z : \operatorname{Arg} z = 0\}$, then reflect in the line $\{z : \operatorname{Arg} z = \frac{1}{2}\theta\}$.

To *translate* the plane $\mathbb{R}^2$ through a vector (a, b): first reflect in the line $\{(x, y) : ax + by = 0\}$, then reflect in the line $\{(x, y) : ax + by = \frac{1}{2}(a^2 + b^2)\}$.

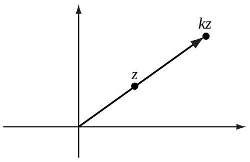
Having discussed isometries, we now turn our attention to two other transformations of the complex plane that preserve the magnitude of angles and map circles and lines to circles and lines.

Scalings

The transformation defined by

$$t(z) = kz \quad (z \in \mathbb{C}), \tag{4}$$

where k is real and positive, multiplies the modulus of each complex number by a factor k but leaves its argument unchanged. It is therefore a *scaling* by the factor k. Clearly, scalings preserve angles, and map circles and lines to circles and lines.



Inversions

The primary reason for introducing complex numbers into our discussion is that they provide a particularly convenient way in which to represent the effect of an inversion on points in the plane.

Theorem 3 An inversion in a circle C of radius r with centre (a, b) may be represented in the complex plane by the transformation

$$t(z) = \frac{r^2}{\overline{z - c}} + c \quad (z \in \mathbb{C} - \{c\}),$$

where $c = a + ib$.

Proof We first consider the case where C is the unit circle $\mathcal{C}$. The image under inversion in $\mathcal{C}$ of the point (x, y) is the point $\left(\frac{x}{x^2+y^2}, \frac{y}{x^2+y^2}\right)$. We may reformulate this expression in terms of complex numbers, by using the fact that the modulus $|z|$ of a complex number $z = x + iy$ satisfies the identity

By Theorem 2, Subsection 5.1.2

$$x^2 + y^2 = |z|^2 = z\bar{z}.$$

Thus the image under inversion of the point $z = x + iy$ is the point

$$\frac{x}{x^2 + y^2} + i\frac{y}{x^2 + y^2} = \frac{x + iy}{x^2 + y^2} = \frac{z}{z\bar{z}} = \frac{1}{\bar{z}}.$$

Next we consider the general case where C is a circle of radius r with centre (a, b). In this case the inversion in C can be expressed as the composite $t = t_3 \circ t_2 \circ t_1$, where

$t_1(z) = \frac{z-c}{r}$ is a translation and a scaling that sends C to the unit circle;

$t_2(z) = 1/\bar{z}$ is the inversion in the unit circle;

$t_3(z) = rz + c$ is the inverse of t_1 and sends the unit circle back to C.

Then

$$t(z) = t_3 \circ t_2 \circ t_1(z) = \frac{r^2}{\overline{z - c}} + c,$$

as required.

The representation of inversion provided by Theorem 3 has a particularly simple form in the case where C is the unit circle $\mathcal{C}$. In that case, $r = 1$ and $c = 0$ so the inversion is represented by the transformation

$$t(z) = \frac{1}{\bar{z}} \quad (z \in \mathbb{C} - \{O\}).$$

You met this formula in the proof of Theorem 3 above.

For example, the image of the point $1 \quad i$ under inversion in the unit circle C is the point

$$\frac{1}{\overline{1 \quad i}} = \frac{1}{1+i} = \frac{1 \quad i}{(1+i)(1 \quad i)} = \tfrac{1}{2}(1 \quad i).$$

Note that the technique of multiplying both numerator and denominator by the conjugate of the denominator is often useful.

Problem 5 Determine, in Cartesian form, the image under inversion in the unit circle C of each of the following points.

(a) $\overline{3} + i$ (b) $3 \quad 4i$

Problem 6 Let C be the circle of radius 2 with centre at the origin. Write down the inversion in C as a transformation of $\mathsf{C} \quad \{O\}$.

We know that inversions preserve the magnitude of angles. But what about their effect on circles and lines? Unfortunately, it is not strictly correct to say that an inversion maps circles and lines to circles and lines since some of the circles and lines may have to be punctured before the map can be carried out. We describe how to overcome this complication later, in Subsection 5.2.3.

By Theorem, Subsection 5.1.3

5.2.2 Linear and Reciprocal Functions

We can use the basic complex functions described in the previous subsection to give a geometric interpretation of many other complex functions. We illustrate this for the so-called *linear* and *reciprocal functions*.

Definition A **linear function** is a function of the form

$$t(z) = az + b \quad (z \quad \mathsf{C}),$$

where a, b C and $a = 0$.

Every linear function $t(z) = az + b$ can be decomposed into a composite $t_2 \quad t_1$ where

t_1 is the scaling $t_1(z) = |a|z$,
t_2 is the isometry $t_2(z) = (a/|a|)z + b$.

The geometrical interpretation of the linear function t depends on how we choose to interpret the isometry t_2. We can say that the linear function is a scaling by the factor $|a|$, followed by a rotation through the angle $\operatorname{Arg}(a/|a|)$, followed by a translation through the vector $(\operatorname{Re} b, \operatorname{Im} b)$. Alternatively, we can use Theorem 2 and say that the linear function is a scaling composed with a number of reflections.

Either way, since both the scaling and the isometry preserve angles and map circles and lines to circles and lines, it follows that the same must be true of all linear functions.

Next, we consider the *reciprocal function*.

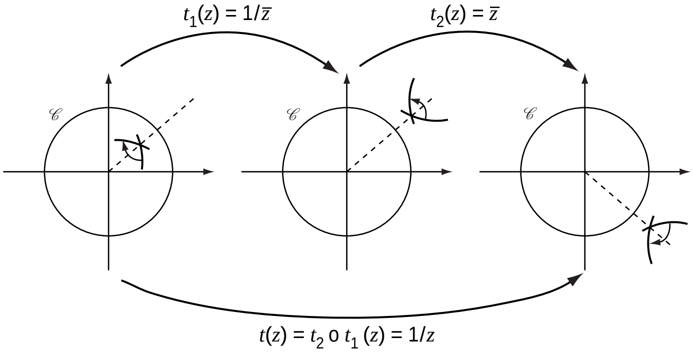
Definition The **reciprocal function** is defined by

$$t(z) = \frac{1}{z} \quad (z \in \mathbb{C} - \{O\}).$$

This function can be decomposed into the composite $t_2 \circ t_1$ where

t_1 is the inversion $t_1(z) = \frac{1}{\bar{z}}$,
t_2 is the conjugation $t_2(z) = \bar{z}$.

It follows that, geometrically, the reciprocal function can be interpreted as an inversion in the unit circle $\mathcal{C}$ followed by a reflection in the real axis, as shown below.



Since the inversion and the conjugation are both one-one functions that preserve the magnitude of angles and reverse their orientation, it follows that the reciprocal function must be a one-one function that preserves both the magnitude and the orientation of angles.

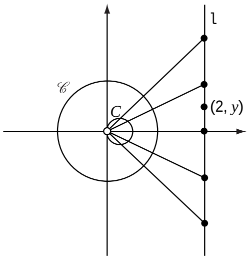
As in the case of inversions, it is not strictly correct to say that the reciprocal function maps circles and lines to circles and lines, because some of the circles and lines may have to be punctured before the reciprocal function can be applied. We next show how we can overcome this complication by extending the complex plane.

5.2.3 The Extended Plane

So far, our discussion of the effect of inversion on lines and circles has been complicated by the need to puncture those lines and circles that pass through the centre of inversion. Also, the need to distinguish between those images that are circles and those that are lines makes the description of the inversion process somewhat cumbersome. We can deal with both these difficulties in a very elegant way by adding an additional point to the plane to obtain the so-called *extended complex plane*.

To illustrate the ideas involved, consider the line with equation $x = 2$. Recall that inversion in the unit circle C maps to a circle C with radius $\frac{1}{4}$ and centre $(\frac{1}{4}, 0)$, punctured at the origin.

Example 5, part (a), Subsection 5.1.2



The point (2, 0) is mapped to $(\frac{1}{2}, 0)$, (2, 1) is mapped to $(\frac{2}{5}, \frac{1}{5})$, (2, 2) is mapped to $(\frac{1}{4}, \frac{1}{4})$, (2, 3) is mapped to $(\frac{2}{13}, \frac{3}{13})$ and, in general, the point $(2, y)$ is mapped to the point $(\frac{2}{4+y^2}, \frac{y}{4+y^2})$ on C. As the point $(2, y)$ moves from (2, 0) *up* the line , its image under inversion moves from $(\frac{1}{2}, 0)$ around the circle C towards the origin in an *anticlockwise* direction. Similarly, as the point $(2, y)$ moves from (2, 0) *down* the line , its image under inversion moves from $(\frac{1}{2}, 0)$ around the circle C towards the origin in a *clockwise* direction. The gap in the circle C at the origin arises because there is no point on , or indeed any point in R^2, that is inverted to the origin. To fill the gap we attach an additional *point at infinity* to the plane.

Definitions The **extended plane** is the union of the Euclidean plane R^2 and one extra point, the **point at infinity**, denoted by the symbol . When we wish to consider the plane as the complex plane C, then we call the extended plane the **extended complex plane** and denote it by the symbol C; thus $\mathsf{C} = \mathsf{C} \quad \{ \quad \}$.

C is read as C hat .

Remarks

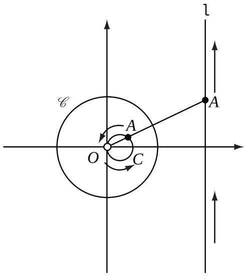
1. The *extended plane* and the *extended complex plane* both consist of the ordinary plane together with the point . We use both terms interchangeably, depending on whether we wish to think of the ordinary points in the plane as being represented by pairs of real numbers or by complex numbers.
2. The symbol does *not* represent a complex number and so it should *not* be used in association with arithmetic operations that act on complex numbers. For example, $+ 3i$ is a meaningless expression.

When we wish to think of points as complex numbers, we often denote them by lower-case letters such as z or a rather than the upper case letters usually used for points.

Having extended the plane in this way, we now extend the definition of inversion in a circle with centre O. We simply define the image of O to be , and the image of to be O. Other points are mapped as specified by the definition of inversion given in Subsection 5.1.1.

A more formal definition of inversion in C is given below.

With this extended definition of inversion, the point O corresponds to , and so the circle C in the above discussion now corresponds under inversion in C to the set $\{ \}$. This certainly fills the gap in C, but how can the set $\{ \}$ be interpreted?



As a point A on the circle C moves anticlockwise towards O, its image A under inversion moves up . When A reaches O, A reaches . As A continues around C below O, its image returns up from below. You can think of the point as linking the two ends of the line , thereby enabling points to travel round and round the line. With some stretch of your imagination, you can therefore think of the line as a circle of infinite radius, where the gap at infinity has been filled by the point .

Any line in the plane may have its gap at infinity filled by forming the set $\{ \}$. Such a set is called an **extended line**. Since an extended line can be thought of as a circle of infinite radius, we make the following definition.

Definition A **generalized circle** in the extended plane is a set that is either a circle or an extended line.

Remark

With this definition, you can think of an extended line as a generalized circle which passes through , and you can think of an ordinary line as a generalized circle which has been punctured at .

Recall that in Subsection 5.1.1 we adopted the convention that an inversion is either a reflection in a line, or an inversion with respect to a circle. We can now regard both of these as inversions in generalized circles.

Definition Let C be a generalized circle in the extended complex plane. Then an **inversion of the extended plane with respect to** C is a function t defined by one of the following rules:

(a) if C is a circle of radius r with centre O, then

$$t(A) = \begin{cases} \text{the inverse of } A \text{ with respect to } C, & \text{if } A \quad \mathbb{C} \quad \{O\},\\ \quad , & \text{if } A = O,\\ O, & \text{if } A = \quad ; \end{cases}$$

(b) if C is an extended line $\{ \}$, then

$$t(A) = \begin{cases} \text{the reflection of } A \text{ in } \quad , & \text{if } A \quad \mathbb{C},\\ \quad , & \text{if } A = \quad . \end{cases}$$

Remember that A' is the inverse of A with respect to C if it lies on the same radial half-line from O as A, and $OA \cdot OA' = r^2$.

Remark

Note that any inversion in an extended line fixes the point at infinity. Conversely, every inversion that fixes must be an inversion in an extended line.

The above definition of inversion ensures that generalized circles map to generalized circles. Indeed, we already know from Subsection 5.1.2 that this is true if we allow the circles to be punctured, but we still need to check that the gap in a punctured circle is mapped to the gap in its image circle.

In the case of inversion with respect to a circle with centre O, we know that a circle or line punctured at O maps to a line, and this is consistent with the fact that O maps to . Also, a line maps to a circle or line that is punctured at O, and this is consistent with the fact that maps to O.

In the case of inversion with respect to an extended line, we know that lines reflect to lines, which is consistent with the fact that maps to . Ordinary circles are not a problem since they reflect onto circles.

We therefore have the following important result.

Theorem 4 Inversions of the extended plane map generalized circles onto generalized circles.

We shall sometimes find it convenient to write inversions of the extended plane as inversions of $\mathbb{C}$. For example, by Theorem 3, we can write the inversion of the extended plane with respect to the unit circle $\mathbb{C}$ in the form

Subsection 5.2.1

$$t(z) = \begin{cases} \frac{1}{\bar{z}}, & \text{if } z \quad \mathbb{C} \quad \{O\}, \\ 0, & \text{if } z = \quad , \\ \quad , & \text{if } z = 0. \end{cases}$$

Problem 7 Write down each of the following inversions of the extended plane as a transformation of $\mathbb{C}$:

(a) the inversion with respect to the circle of radius 2 with centre the origin;

(b) the inversion with respect to the extended real axis.

The inversion of the extended plane that we asked you to write down in Problem 7, part (b), is particularly important because it provides us with a natural way of extending the conjugation function from $\mathbb{C}$ to $\mathbb{C}$.

Definition The function $t : \mathbb{C} \quad \mathbb{C}$ defined by

$$t(z) = \begin{cases} \bar{z}, & \text{if } z \quad \mathbb{C}, \\ \quad , & \text{if } z = \quad , \end{cases}$$

is called the **extended conjugation function**.

This function occurs so frequently that we shall introduce a notation for the images of the points in its domain. Since we already have the notation $\bar{z}$ for the conjugate of a complex number z, we simply adopt the convention that $\overline{} = $.

Inversions are not the only transformations that can be extended to $\mathbb{C}$. Indeed, most of the transformations discussed at the beginning of this section can be extended in a natural way to $\mathbb{C}$.

Definitions

(a) The function $t : \hat{\mathbb{C}} \to \hat{\mathbb{C}}$ defined by

$$t(z) = \begin{cases} \dfrac{1}{z}, & \text{if } z \in \mathbb{C} - \{0\}, \\ \infty, & \text{if } z = 0, \\ 0, & \text{if } z = \infty, \end{cases}$$

is called the **extended reciprocal function**.

(b) A function $t : \hat{\mathbb{C}} \to \hat{\mathbb{C}}$ of the form

$$t(z) = \begin{cases} az + b, & \text{if } z \in \mathbb{C}, \\ \infty, & \text{if } z = \infty, \end{cases}$$

where $a, b \in \mathbb{C}$ and $a \neq 0$, is called an **extended linear function**.

Since scalings, rotations and translations are all special types of linear function, they too are extended to $\hat{\mathbb{C}}$ by this definition.

The solution to the next example shows that the extended reciprocal function can be expressed as a composite of two inversions.

Example 2 Find the composite $t = t_2 \circ t_1$ where

t_1 is the inversion in the unit circle $\mathcal{C}$,
t_2 is the extended conjugation function.

Solution Since

$$t_1(z) = \begin{cases} \dfrac{1}{\bar{z}}, & \text{if } z \in \mathbb{C} - \{0\}, \\ \infty, & \text{if } z = 0, \\ 0, & \text{if } z = \infty, \end{cases} \quad \text{and} \quad t_2(z) = \begin{cases} \bar{z}, & \text{if } z \in \mathbb{C}, \\ \infty, & \text{if } z = \infty, \end{cases}$$

we have

$$t(\infty) = t_2 \circ t_1(\infty) = t_2(0) = 0,$$
$$t(0) = t_2 \circ t_1(0) = t_2(\infty) = \infty.$$

For the remaining values of $z \in \mathbb{C} - \{0\}$ we have

$$t(z) = t_2 \circ t_1(z) = t_2\left(\frac{1}{\bar{z}}\right) = \overline{\left(\frac{1}{\bar{z}}\right)} = \frac{1}{z}.$$

It follows that $t = t_2 \circ t_1$ is the extended reciprocal function. □

Next we describe how an extended linear function can be expressed as a composite of inversions. In preparation for this, we ask you to tackle the following problem.

Problem 8 Find the composite $t = t_2\ \ t_1$ where

t_1 is the inversion with respect to the unit circle C ,
t_2 is the inversion with respect to the circle of radius 2 with centre 0.

Give an interpretation of the composite function t. Also describe what would happen if the circle of radius 2 were replaced by a circle of radius $\overline{k}$ with centre 0.

Earlier, we noted that every linear function is a composite $t\ \ s$ of a scaling s followed by an isometry t. Since every isometry t is a composite of reflections, it follows that every linear function is a composite $r_n\ \ \ldots\ \ r_2\ \ r_1\ \ s$ of a scaling s followed by a number of reflections $r_1, r_2, \ldots, r_n$.

Now the only difference between a linear function and an *extended* linear function is that the latter contains an additional point at infinity in its domain. Since this additional point maps to itself, it follows that an extended linear function is a composite of a scaling that also fixes , followed by a number of reflections that also fix .

But a reflection that fixes is just an inversion in an extended line. Also, by the solution to Problem 8, a scaling that also fixes is a composite of two inversions. It follows that every extended linear function is a composite of inversions.

Combining this with the result of Example 2 above we have the following theorem.

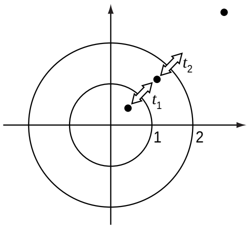
Theorem 5 The extended reciprocal function and the extended linear functions can be decomposed into composites of inversions.

Since inversions of the extended plane map generalized circles onto generalized circles, we have the following corollary of Theorem 5.

Corollary The extended linear functions and the extended reciprocal function map generalized circles onto generalized circles.

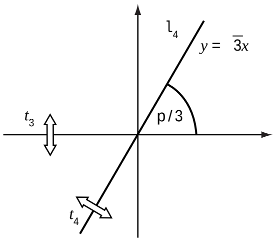
Example 3 Let t be the extended linear function defined by

$$t(z) = \begin{cases} 2\ \ \ 1+\ \overline{3}i\ \ z + (4\ \ \ 2i), & \text{if } z\ \ \ \mathsf{C},\\ & \text{if } z = \ \ . \end{cases}$$



Express t as a composite of inversions of the extended complex plane.

Solution In addition to mapping to , the transformation t *scales* the complex plane by the factor $|2(\ \ 1+\ \ \overline{3}i)| = 4$, *rotates* it through the angle $\text{Arg}\,(2(\ \ 1+\ \ \overline{3}i)) = \frac{2}{3}$, and then *translates* it through the vector $(4,\ \ 2)$.



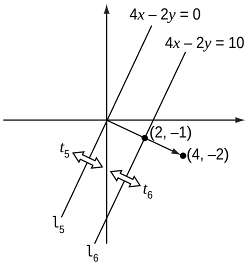
The *scaling* by the factor 4 can be decomposed into the composite $t_2 \circ t_1$, where

t_1 is the inversion in the unit circle $\mathbb{C}$,
t_2 is the inversion in the circle of radius $\sqrt{4} = 2$ centred at the origin.

The *rotation* through the angle $2\pi/3$ can be decomposed into the composite $t_4 \circ t_3$, where

t_3 is the inversion in the extended real axis,
t_4 is the inversion in the extended line $\ell_4 \cup \{\infty\}$, where ℓ_4 is the line $y = \sqrt{3}x$.

(Here ℓ_4 is the line through the origin that makes an angle $\pi/3$ with the x-axis.)



The *translation* through the vector $(4, -2)$ can be decomposed into the composite $t_6 \circ t_5$, where

t_5 is the inversion in the extended line $\ell_5 \cup \{\infty\}$, where ℓ_5 is the line $4x - 2y = 0$,
t_6 is the inversion in the extended line $\ell_6 \cup \{\infty\}$, where ℓ_6 is the line $4x - 2y = 10$.

(Note that ℓ_5 is the line through the origin that is perpendicular to the vector $(4, -2)$, and ℓ_6 is the line that passes through $(2, -1)$ parallel to ℓ_5.)

Since t_6, t_5, t_4, t_3 and $t_2 \circ t_1$ all map ∞ to itself, it follows that

$$t = t_6 \circ t_5 \circ t_4 \circ t_3 \circ t_2 \circ t_1. \qquad \square$$

Problem 9 Let t be the extended linear function defined by

$$t(z) = \begin{cases} 9z + (6 - 10i), & \text{if } z \in \mathbb{C}, \\ \infty, & \text{if } z = \infty. \end{cases}$$

Express t as a composite of inversions of the extended complex plane.
Hint: Use the decompositions described in the margin.

The decompositions illustrated above generalize as follows.

To *scale* $\mathbb{C}$ by a factor k: first invert in the circle $\{z : |z| = 1\}$, then invert in the circle $\{z : |z| = \sqrt{k}\}$.

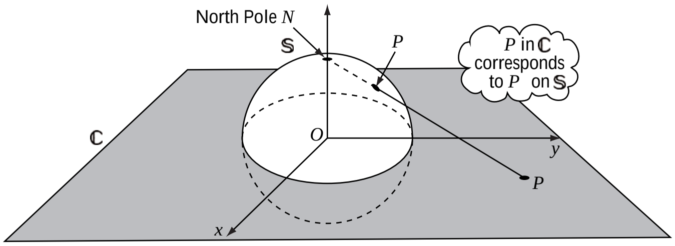
To *rotate* $\mathbb{C}$ through an angle θ: first invert in the extended line $\{z : \operatorname{Arg} z = 0\} \cup \{\infty\}$, then invert in the extended line $\{z : \operatorname{Arg} z = \frac{1}{2}\theta\} \cup \{\infty\}$.

To *translate* $\mathbb{C}$ through a vector (a, b): first invert in the extended line $\{(x, y) : ax + by = 0\} \cup \{\infty\}$, then invert in the extended line $\{(x, y) : ax + by = \frac{1}{2}(a^2 + b^2)\} \cup \{\infty\}$.

5.2.4 The Riemann Sphere

In the previous subsection, we introduced the point at infinity and the extended complex plane in order to provide a simplified explanation of the effect of inversion on lines and circles. However, it may seem unsatisfactory to have to visualize a straight line as a (generalized) circle, since the 'ends' of the line appear to be infinitely far apart. Also, it is difficult to visualize where the point at infinity should be placed relative to $\mathbb{C}$, other than to think of it as smeared in some vague way around the 'outer edge' of $\mathbb{C}$.

Fortunately, there is a model of the extended (complex) plane in which the point at infinity appears as an actual point! Consider the complex plane $\mathbb{C}$ as lying in $\mathbb{R}^3$ with the real and imaginary axes aligned along the x-axis and y-axis, respectively. Then each complex number $x + iy$ may be represented by the point $(x, y, 0)$ in the (x, y)-plane.



Next, draw the sphere S with centre at the origin and with radius 1; we call this the **Riemann sphere**. By analogy with the Earth, we refer to the point $N = (0, 0, 1)$ at the top of the sphere as the **North Pole** of S, and the point $S = (0, 0, \quad 1)$ at the bottom of the sphere as the **South Pole** of S.

Each line joining a point P in the complex plane to the North Pole intersects the Riemann sphere at some point P , and vice versa. In this way, we obtain a one one correspondence between all points P in the complex plane and all but one of the points P on the sphere. The one point on the sphere that cannot be associated with a point in the complex plane is the North Pole N.

As the point P on the sphere moves closer to N, the corresponding point P in the plane moves further away from the origin O. This suggests that we associate the North Pole N with the point in the extended complex plane.

The function $: \mathsf{S} \quad \mathsf{C}$, which maps points on the Riemann sphere to the associated points in the extended complex plane, is called **stereographic projection**. Since is one one and onto, it follows that we can use the Riemann sphere as a convenient visualization of the extended complex plane C.

In fact, we can find an explicit formula for stereographic projection of the point (X, Y, Z) onto the point $z = x + iy$, and vice versa.

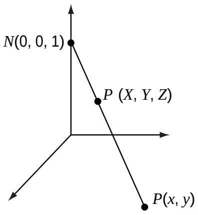
We use capital letters to denote coordinates of points in R^3, and small letters to denote points or coordinates in the complex plane.

Theorem 6 Let denote the mapping of the Riemann sphere S onto C given by stereographic projection. Then the stereographic projection of the point (X, Y, Z) of S onto the point $z = x + iy$ of C is given by

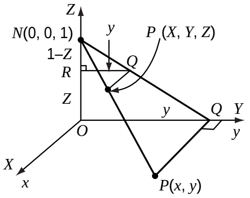
$$(X, Y, Z) = \frac{X}{1 \quad Z} + i\frac{Y}{1 \quad Z}.$$

Also, the inverse mapping is given by

$$^{1}(x + iy) = \frac{2x}{x^2 + y^2 + 1}, \frac{2y}{x^2 + y^2 + 1}, \frac{x^2 + y^2 \quad 1}{x^2 + y^2 + 1} \quad .$$



Proof Let the point $P\ (X, Y, Z)$ be a point on S (other than N), and $P(x, y)$ the point in the plane that corresponds to P under stereographic projection. Project the line $NP\ P$ perpendicularly onto the (Y, Z)-plane, with P and P projecting onto the points Q and Q; then Q and Q have coordinates $(0, Y, Z)$ and $(0, y, 0)$ in R^3. Draw the perpendicular $Q\ R$ from Q to the Z-axis.



Since RQ is parallel to OQ, the triangles NRQ and NOQ are similar. It follows that $NR : RQ = NO : OQ$, or

$$\frac{1-Z}{Y} = \frac{1}{y},$$

from which we obtain that

$$y = \frac{Y}{1-Z}.$$

By projecting the line $NP P$ onto the (X, Z)-plane and using a similar argument, we can show that

We omit the details.

$$x = \frac{X}{1-Z}.$$

It then follows that the mapping is given by

$$(X, Y, Z) = x + iy = \frac{X}{1-Z} + i\frac{Y}{1-Z}.$$

Clearly this formula also holds when N is mapped to .

For, here $Z = 1$.

To find the formula for ^{1}, we use the fact that $X^2 + Y^2 + Z^2 = 1$. Substituting the values of X and Y from the above formulas into the equation $X^2 + Y^2 + Z^2 = 1$ and doing some manipulation, we deduce that

We omit the details.

$$x^2 + y^2 + 1 = \frac{2}{1-Z}. \tag{5}$$

It follows from equation (5) and the earlier equations for X and Y that

$$X = x(1-Z) = \frac{2x}{x^2 + y^2 + 1}$$

and

$$Y = y(1-Z) = \frac{2y}{x^2 + y^2 + 1}.$$

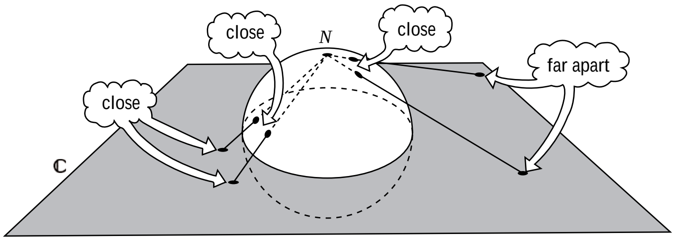
Also, we may rearrange equation (5) in the form

$$Z = \frac{x^2 + y^2 - 1}{x^2 + y^2 + 1}.$$

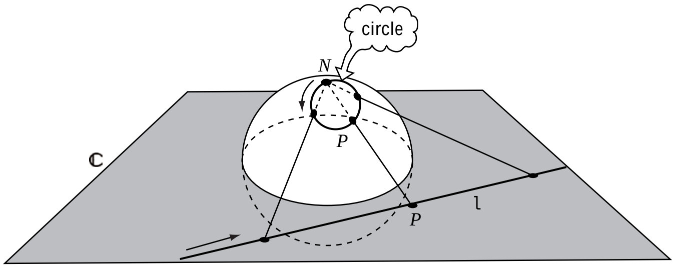
We can then combine these formulas to give the required formula for ^{1}:

$$\begin{aligned} {}^{1}(x + iy) &= (X, Y, Z) \\ &= \left(\frac{2x}{x^2 + y^2 + 1}, \frac{2y}{x^2 + y^2 + 1}, \frac{x^2 + y^2 - 1}{x^2 + y^2 + 1}\right). \end{aligned}$$

Notice that stereographic projection distorts the distances between points. For example, two points that are close together on S may project onto points that are close together in C, or onto points that are far from each other in C.



We can use the Riemann sphere to visualize extended lines as generalized circles in a very natural way, as follows. Consider a point P on a line in ℂ.



As P moves along , the line that joins P to the North Pole sweeps out the plane through and N; this intersects the sphere in a circle. Hence, as P moves along , the corresponding point P on the sphere traces out a circle. As P moves further out along the line, the point P moves towards the North Pole. The point P never actually reaches the North Pole, since the North Pole corresponds to the *gap* in the line that we mentioned earlier.

Subsection 5.2.3

We filled the gap in by attaching to to obtain the extended line { } in ℂ. On the sphere, the point N fills the corresponding gap in the circle, so that the extended line { } corresponds to an *actual* circle on the sphere in fact, a circle through N.

This fact is a particular instance of the following general result.

Theorem 7 Under stereographic projection, circles on the Riemann sphere map onto generalized circles in ℂ.

In particular, circles on the sphere that pass through N map onto extended lines in ℂ, and circles on the sphere that do not pass through N map onto ordinary circles in ℂ.

Proof A circle on the sphere is the intersection of the sphere $X^2 + Y^2 + Z^2 = 1$ with some plane $aX + bY + cZ + d = 0$, where a, b and c are not all zero. It follows from substituting the expressions

$$X = \frac{2x}{x^2 + y^2 + 1}, \quad Y = \frac{2y}{x^2 + y^2 + 1} \quad \text{and} \quad Z = \frac{x^2 + y^2 \quad 1}{x^2 + y^2 + 1},$$

You met these equations in the proof of Theorem 6 above.

for X, Y and Z into the equation $X^2 + Y^2 + Z^2 = 1$ that

$$\frac{2ax + 2by + c \quad x^2 + y^2 \quad 1}{x^2 + y^2 + 1} + d = 0.$$

This equation may be rewritten in the form

$$2ax + 2by + c \quad x^2 + y^2 \quad 1 \quad + d \quad x^2 + y^2 + 1 \quad = 0,$$

or

$$(c + d)x^2 + (c + d)y^2 + 2ax + 2by + (d \quad c) = 0.$$

It follows that the image of a circle on the sphere is a generalized circle in the (extended) plane.

For its equation is that of a circle or of an (extended) line.

The circle on the sphere passes through $N(0, 0, 1)$ if the plane $aX + bY + cZ + d = 0$ passes through N, and so if $c + d = 0$.

It follows that if the circle on the sphere passes through N, its image in the extended plane has an equation of the form

$$2ax + 2by + (d \quad c) = 0,$$

and is an extended line.

On the other hand, if the circle on the sphere does not pass through N, then $c + d = 0$ and its image is an ordinary circle in the plane.

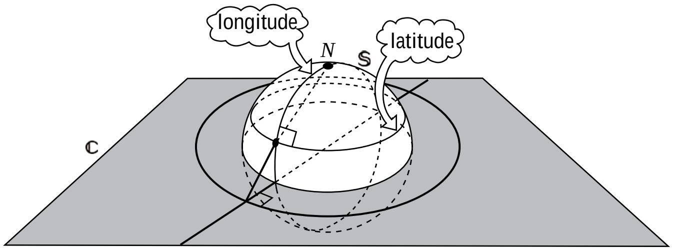
Problem 10 Determine the images under stereographic projection onto $\mathbb{C}$ of the following circles on $\mathbb{S}$.

(a) The circle $\{(X, Y, Z) : X^2 + Y^2 + Z^2 = 1, X = \frac{1}{2}\}$

(b) The circle of intersection of $\mathbb{S}$ with the plane $3X + 2Y + Z = 1$

As an illustration of Theorem 7, we describe what happens to the lines of latitude and longitude of the Riemann sphere under stereographic projection.

A line of longitude on the Riemann sphere is a circle on $\mathbb{S}$ that passes through the North Pole and the South Pole of $\mathbb{S}$; this projects onto a line through the origin in the plane. Similarly, a line of latitude on the Riemann sphere is a circle at a constant height above the (x, y)-plane, so, by symmetry, this projects onto a circle centred at the origin in the plane.

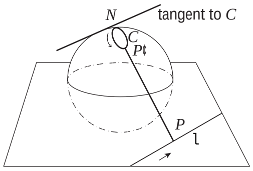


Just as the lines of latitude and longitude meet at right angles on the sphere, so do their projections. This is a consequence of the following remarkable result.

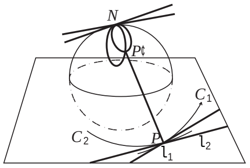
Theorem 8 Stereographic projection preserves the magnitude of angles.

Recall that inversion has a similar property (see Theorem 5, Subsection 5.1.3).

Proof First, we make the following crucial observation. Recall that if a point P moves along a line ℓ in the complex plane, then the corresponding point P' on the Riemann sphere moves round a circle through N. Indeed, as P moves out towards ∞, P' approaches N; and the line NP' (in $\mathbb{R}^3$) approaches the tangent at N to the circle on the sphere. It follows that the tangent at N to the circle on the sphere must be parallel to the original line ℓ.



Let C_1 and C_2 be curves in the complex plane that intersect at some point P, and let ℓ_1 and ℓ_2 be the tangents to C_1 and C_2 at P. (Recall that we define the angle between C_1 and C_2 at P to be the angle between ℓ_1 and ℓ_2 at P.)



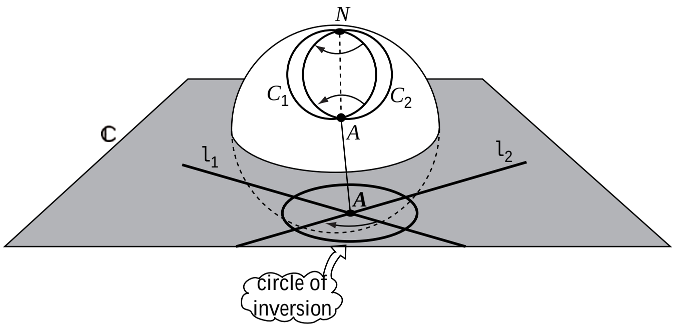
The curves on the Riemann sphere that correspond to ℓ_1 and ℓ_2 are circles through the North Pole N and the point P' on the sphere that corresponds to the point P in the plane. We have to show that the angle between these circles at P' (that is, the angle between their tangents at P') is equal to the angle between the lines ℓ_1 and ℓ_2 at P.

But, by symmetry, the angle between the circles at P' is equal to the angle between the same circles when they meet again at N. And, as we saw above, the lines ℓ_1 and ℓ_2 through P are parallel to the corresponding tangent lines through N. Thus the angle between the circles at N must be equal to the original angle between ℓ_1 and ℓ_2 at P.

Hence, stereographic projection does preserve the magnitude of angles, as asserted.

Earlier, we showed that inversion preserves the magnitude of angles but reverses their orientation. Having introduced the Riemann sphere, we can now show that there is a sense in which this is true even for angles which have a vertex at the centre of inversion, or at ∞.

To see this, let ℓ_1 and ℓ_2 be two lines that intersect at the centre of inversion A. The corresponding extended lines $\ell_1 \cup \{\infty\}$ and $\ell_2 \cup \{\infty\}$ intersect again at the point ∞. On the Riemann sphere these extended lines become circles C_1 and C_2 that intersect at the North Pole and at the point A' corresponding to A.



Under the inversion, each extended line maps to itself, so C_1 and C_2 also map to themselves. Notice, however, that the points A and N swap over, and so the angles at A and N swap over as well. By symmetry, these angles are equal in magnitude but opposite in direction. So, provided we interpret the angle between curves at as the corresponding angle on the Riemann sphere, we can conclude that the fact that inversion preserves the magnitude of angles holds throughout the whole of $\mathbb{C}$.

5.3 Inversive Geometry

5.3.1 Inversive Geometry

We now come to the main purpose of this chapter, which is to introduce a geometry, known as *inversive geometry*, that we can use to study the properties of circles, lines and angles.

Recall that according to Klein, a geometry has the following ingredients:

Introduction to Chapter 2, before Subsection 2.1.1

a space consisting of a set of points;
a group of transformations that act on the space.

Each geometry is used to study those properties of figures in its space that are preserved by its transformations. For example, Euclidean geometry is used to study those properties of figures in $\mathbb{R}^2$, such as angle and distance, that are preserved by the isometries of $\mathbb{R}^2$.

Since each isometry of $\mathbb{R}^2$ can be decomposed into a composite of reflections, we can think of the group associated with Euclidean geometry as the group of all possible composites of reflections.

This provides the clue that we need to define the transformations of our new geometry. Rather than consider composites of reflections, we consider composites of inversions.

Definition A transformation $t : \mathbb{C} \quad \mathbb{C}$ is an **inversive transformation** if it can be expressed as a composite of inversions.

It is important to distinguish between inversions and inversive transformations.

For example, the extended reciprocal function is an inversive transformation because it can be expressed as a composite $t_2 \quad t_1$ where t_1 is the inversion in the unit circle and t_2 is the inversion in the real axis. Similarly, all extended linear functions can be expressed as composites of inversions, so they too are inversive transformations.

Theorem 1 The extended reciprocal function and the extended linear functions are inversive transformations.

Since every inversion preserves the magnitude of angles and maps generalized circles to generalized circles, the same must be true of all composites of inversions. We therefore have the following result.

Theorem 2 Inversive transformations preserve the magnitude of angles, and map generalized circles to generalized circles.

Before we can use the inversive transformations to define a geometry, we must first check that they form a group.

Theorem 3 The set of inversive transformations forms a group under the operation of composition of functions.

Proof We check that the four group axioms hold.

G1 CLOSURE Let r and s be inversive transformations. Then we can write

$$r = t_1 \circ t_2 \circ \ldots \circ t_k$$

and

$$s = t_{k+1} \circ t_{k+2} \circ \ldots \circ t_n,$$

where $t_1, t_2, \ldots, t_n$ are inversions. Thus

$$r \circ s = (t_1 \circ t_2 \circ \ldots \circ t_k) \circ (t_{k+1} \circ t_{k+2} \circ \ldots \circ t_n)$$

is a composite of inversions, and is therefore an inversive transformation.

G2 IDENTITY The identity for composition of functions is the identity transformation given by

$$t(z) = z \quad (z \in \mathbb{C}).$$

This is an inversive transformation since $t = s \circ s$, where s is the inversion in the unit circle.

Here we could have chosen any other inversion for s since all inversions are self-inverse.

G3 INVERSES If t is an inversive transformation, then we can write

$$t = t_1 \circ t_2 \circ \ldots \circ t_n,$$

where $t_1, t_2, \ldots t_n$ are inversions. It follows that t has inverse

$$t^{-1} = t_n^{-1} \circ t_{n-1}^{-1} \circ \ldots \circ t_1^{-1} = t_n \circ t_{n-1} \circ \ldots \circ t_1,$$

which is an inversive transformation.

G4 ASSOCIATIVITY Composition of functions is always associative.

Since all four group properties hold, it follows that the set of inversive transformations forms a group under composition of functions.

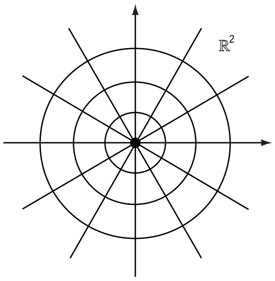
Having shown that the inversive transformations form a group, we can use them to define a geometry. But what space should we use for the geometry? Since the inversive transformations act on $\mathbb{C}$, the space will have to be $\mathbb{C}$. But what do figures look like in this space? Just as figures in $\mathbb{R}^2$ are defined to be subsets of $\mathbb{R}^2$, so **figures in $\mathbb{C}$** are defined to be subsets of $\mathbb{C}$. Thus circles and extended lines are both examples of figures in $\mathbb{C}$. We can now make the following definition.

Definition **Inversive geometry** is the study of those properties of figures in $\mathbb{C}$ that are preserved by inversive transformations.

We have already met the following inversive properties: generalized circles, magnitude of angles, and tangency (since zero angles are preserved).

5.3.2 Relationship with Other Geometries

Although the point at infinity is crucial to the theory of inversive geometry, when we come to interpret results about figures we often choose to confine our attention to points in $\mathbb{C}$. By ignoring the point ∞ in this way, the remaining points in $\mathbb{C}$ can be interpreted as points of $\mathbb{R}^2$ and any extended lines in the figure can be interpreted as ordinary lines.

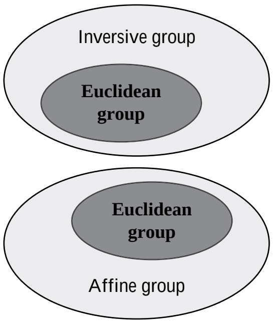


In this sense figures in $\mathbb{R}^2$ can be interpreted as figures in $\mathbb{C}$, and vice versa. For example, the figure in the margin is a figure in $\mathbb{R}^2$. It consists of a family of circles centred at the origin, and a family of lines that intersect at the origin. If we add the point ∞ to the figure, then all the lines become generalized circles and the figure becomes a figure in $\hat{\mathbb{C}}$.

Earlier, you saw that every Euclidean transformation can be expressed as a composite of reflections. Since a reflection can be interpreted as an inversion that fixes ∞, it follows that we can interpret every Euclidean transformation as a composite of inversions, and hence as an inversive transformation.

We could make this interpretation precise by adopting the convention that a Euclidean transformation maps ∞ to ∞ when it acts on $\hat{\mathbb{C}}$.

An immediate consequence of the above observations is that when figures in $\mathbb{C}$ are interpreted as figures in $\mathbb{R}^2$, all their inversive properties become Euclidean properties. This is because any property that is preserved by all inversive transformations must also be preserved by all Euclidean transformations. For example, the magnitude of angles is both an inversive and a Euclidean property.



A pictorial representation of the relationship between inversive and Euclidean geometry is given in the margin. Provided that we ignore the point ∞, the group of Euclidean transformations can be regarded as a subgroup of the group of inversive transformations. Because the Euclidean group is smaller than the inversive group, it follows that Euclidean geometry has more properties than does inversive geometry. For example, length is a Euclidean property but it is not an inversive property.

How does affine geometry fit into the scheme? In Subsection 2.2.1 we showed that every Euclidean transformation is an affine transformation. But what is the relationship between affine transformations and inversive transformations?

Certainly, some affine transformations are inversive without being Euclidean. For example, earlier you saw that the doubling map t,

See Subsection 2.2.3

$$t(z) = 2z \quad (z \in \mathbb{C}),$$

is an affine transformation. This transformation is not a Euclidean transformation, and yet it can be decomposed into the composite $t_2 \quad t_1$, where t_1 is the inversion in the unit circle C, and t_2 is the inversion in the circle $\{|z| = \quad \overline{2} : z \quad \mathrm{C}\}$. So, with the usual proviso about , t is an inversive transformation.

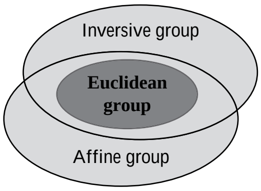
You saw how a scaling can be decomposed into a composite of inversions in Problem 8, Subsection 5.2.3.

However, not all affine transformations are inversive transformations. For example, the transformation

$$t(\mathbf{x}) = \begin{pmatrix} 2 & 0 \\ 0 & 1 \end{pmatrix} \mathbf{x} \qquad \mathbf{x} \quad \mathrm{R}^2$$

represents a horizontal shear. This cannot be an inversive transformation, since it does not preserve angles.

It follows that the affine group of transformations contains the Euclidean group but overlaps the inversive group, as illustrated in the margin.



5.3.3 Möbius Transformations

To enable us to tackle problems in inversive geometry algebraically, we need an algebraic representation of the inversive transformations.

We shall show that each inversive transformation has either the form $t(z) = M(z)$, or the form $t(z) = M(\bar{z})$, where M is a so-called *Möbius transformation*.

Definition A **Möbius transformation** is a function $M : \mathrm{C} \quad \mathrm{C}$ of the form

$$M(z) = \frac{az + b}{cz + d},$$

where $a, b, c, d \quad \mathrm{C}$ and $ad \quad bc = 0$.

If $c = 0$, then we adopt the convention that $M(\quad) = \quad$; otherwise, we adopt the convention that $M(\quad d/c) = \quad$ and $M(\quad) = a/c$.

Remarks

1. Every (extended) linear function is a Möbius transformation, as can be seen by setting $c = 0$, $d = 1$. Also, the (extended) reciprocal function is a Möbius transformation with $a = d = 0$ and $b = c = 1$.
2. If $c = 0$, then the formula for M reduces to $M(z) = (a/d)z + (b/d)$. This defines an extended linear function, because the condition $ad \quad bc = 0$ ensures that both a and d are non-zero, and so a/d is also non-zero. Also, the convention that $M(\quad) = \quad$ complies with the definition of an extended linear function.
3. The condition $ad \quad bc = 0$ is equivalent to the statement that the ratios $a : c$ and $b : d$ are unequal. This is necessary to ensure that the numerator is not simply a multiple of the denominator, for if it were, M would be a constant function.

For example,

$6i \times 2 \quad 4i \times 3 = 0,$

so that

$\frac{6iz + 4i}{3z + 2} = 2i$, a constant.

Problem 1 Which of the following formulas define a Möbius transformation?

(a) $M(z) = \frac{5}{z}$ (b) $M(z) = \frac{z + 2i}{3z \quad 4i}$

(c) $M(z) = \quad 3z + \frac{i}{z}$ (d) $M(z) = 1 + \frac{5}{z + 2i}$

For those formulas that do define a Möbius transformation, state the image of under M.

Before we look at the properties of Möbius transformations, we first verify that a Möbius transformation is indeed an inversive transformation.

Theorem 4 Every Möbius transformation is an inversive transformation.

Proof Let M be the Möbius transformation defined by the formula

$$M(z) = \frac{az + b}{cz + d}.$$

If $c = 0$, then M is an extended linear function, and is therefore an inversive transformation.

If $c = 0$, then for $z \quad \mathbb{C} \quad \{ \quad d/c\}$ we can write

$$\begin{aligned} M(z) &= \frac{ad + bc + a(cz + d)}{c(cz + d)} \\ &= \quad \frac{ad \quad bc}{c} \bullet \frac{1}{cz + d} \quad + \frac{a}{c}. \end{aligned}$$

It follows that M may be expressed as the composite $t_3 \quad t_2 \quad t_1$, where t_2 is the extended reciprocal function, and t_1 and t_3 are the extended linear functions

$$t_1(z) = \begin{cases} cz + d, & \text{if } z = \quad , \\ \quad , & \text{if } z = \quad , \end{cases}$$

and

$$t_3(z) = \begin{cases} ((ad \quad bc)/c)z + (a/c), & \text{if } z = \quad , \\ \quad , & \text{if } z = \quad . \end{cases}$$

Next, we check that the transformations $t_3 \quad t_2 \quad t_1$ and M agree also at the exceptional points and $\quad d/c$, as follows:

$$t_3 \quad t_2 \quad t_1(\quad) = t_3 \quad t_2(\quad) = t_3(0) = a/c = M(\quad);$$

$$t_3 \quad t_2 \quad t_1(\quad d/c) = t_3 \quad t_2(0) = t_3(\quad) = \quad = M(\quad d/c).$$

Since the extended reciprocal function and the extended linear functions are inversive transformations, it follows that M is an inversive transformation.

Since Möbius transformations are inversive transformations, they must preserve the magnitude of angles and map generalized circles to generalized circles. In fact, we can say slightly more than this, for in the proof of Theorem 4 we showed that every Möbius transformation is either an extended linear function or a composite of two extended linear functions and an extended reciprocal function. Since the extended linear functions and the extended reciprocal function preserve both the magnitude and *orientation* of angles, the same must be true of Möbius transformations.

Theorem 5 Möbius transformations preserve the magnitude and orientation of angles, and map generalized circles onto generalized circles.

5.3.4 Matrix Representation of Möbius Transformations

In order to explore some of the other properties of Möbius transformations, it is helpful to establish a correspondence between Möbius transformations and matrices.

Recall that, if $a, b, c, d, e, f, g, h \in \mathbb{C}$, then 2×2 matrices have the following properties:

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix} \bullet \begin{pmatrix} e & f \\ g & h \end{pmatrix} = \begin{pmatrix} ae + bg & af + bh \\ ce + dg & cf + dh \end{pmatrix},$$

and

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix}^{-1} = \frac{1}{ad - bc} \begin{pmatrix} d & -b \\ -c & a \end{pmatrix}, \quad \text{if } ad - bc \neq 0.$$

Here, the condition $ad - bc \neq 0$ for the matrix to be invertible is reminiscent of the condition $ad - bc \neq 0$ that appears in the definition of a Möbius transformation. This suggests the following fruitful connection between Möbius transformations and 2×2 invertible matrices.

Definition Let M be a Möbius transformation defined by

$$M(z) = \frac{az + b}{cz + d}, \tag{1}$$

where $a, b, c, d \in \mathbb{C}$. Then

$$\mathbf{A} = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$$

is a matrix **associated** with M.

Remark

1. Every matrix $\begin{pmatrix} a & b \\ c & d \end{pmatrix}$ associated with a Möbius transformation $M(z) = \frac{az+b}{cz+d}$ is invertible because $ad - bc \neq 0$.

2. A matrix associated with a Möbius transformation M is not unique, because we can multiply the numerator and denominator of the formula (1) by the same non-zero constant without altering the transformation. For example, both
$$M(z) = \frac{2z + i}{3z + 2i} \quad \text{and} \quad M(z) = \frac{2iz \quad 1}{3iz \quad 2}$$
specify the same Möbius transformation M, and so both the matrices
$$\begin{matrix} 2 & i \\ 3 & 2i \end{matrix} \quad \text{and} \quad \begin{matrix} 2i & 1 \\ 3i & 2 \end{matrix}$$
are associated with M.

   In general, if $\mathbf{A}$ is a matrix associated with a Möbius transformation M, then for any non-zero $c \quad \mathbb{C}$, $c\mathbf{A}$ is also a matrix associated with M. In fact, every matrix associated with M has the form $c\mathbf{A}$ for some $c \quad \mathbb{C} \quad \{0\}$.

Example 1 Decide which, if any, of the matrices
$$\mathbf{A}_1 = \begin{matrix} 0 & 4 \\ i & 0 \end{matrix}, \quad \mathbf{A}_2 = \begin{matrix} 8 & 0 \\ 2i & 8 \end{matrix}, \quad \mathbf{A}_3 = \begin{matrix} 4i & 0 \\ 0 & 1 \end{matrix}$$
are associated with each of the following Möbius transformations M.

(a) $M(z) = \dfrac{3iz + 2}{z \quad 3i}$ (b) $M(z) = \dfrac{4i}{z}$ (c) $M(z) = \dfrac{4iz}{z \quad 4i}$

Solution

(a) Every matrix associated with this M is a non-zero multiple of the matrix
$$\begin{matrix} 3i & 2 \\ 1 & 3i \end{matrix}.$$
Hence none of the three given matrices is associated with M.

(b) Every matrix associated with this M is a non-zero multiple of the matrix
$$\mathbf{A} = \begin{matrix} 0 & 4i \\ 1 & 0 \end{matrix}.$$
Since $\mathbf{A}_1 = i\mathbf{A}$, it follows that $\mathbf{A}_1$ is a matrix associated with M.

(c) Every matrix associated with this M is a non-zero multiple of the matrix
$$\mathbf{A} = \begin{matrix} 4i & 0 \\ 1 & 4i \end{matrix}.$$
Since $\mathbf{A}_2 = \quad 2i\mathbf{A}$, it follows that $\mathbf{A}_2$ is a matrix associated with M. □

Problem 2 Decide which, if any, of the matrices
$$\mathbf{A}_1 = \begin{matrix} 0 & 1 \\ \frac{1}{2}i & 0 \end{matrix}, \quad \mathbf{A}_2 = \begin{matrix} 0 & 2 \\ 1 & 2i \end{matrix}, \quad \mathbf{A}_3 = \begin{matrix} 2i & 0 \\ 1 & i \end{matrix}$$

are associated with each of the following Möbius transformations M.

(a) $M_1(z) = \dfrac{2i}{iz+2}$ (b) $M_2(z) = \dfrac{2i}{z}$ (c) $M_3(z) = \dfrac{iz+2}{2z-i}$

A particularly important transformation of $\mathbb{C}$ is the *identity* function defined by

$$t(z) = z \quad (z \in \mathbb{C}).$$

This is a Möbius transformation because it can be written in the form

$$t(z) = \frac{z+0}{0z+1}.$$

A matrix associated with this Möbius transformation is the identity matrix

$$\mathbf{I} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}.$$

5.3.5 Composing Möbius Transformations

The next example illustrates what happens when two Möbius transformations are composed.

Example 2 Determine the composite $M_1 \circ M_2$, where M_1 and M_2 are the Möbius transformations defined by

$$M_1(z) = \frac{iz+1}{2z-2} \quad \text{and} \quad M_2(z) = \frac{z+i}{2z-1}.$$

Solution Since M_1 and M_2 are one-one mappings of $\mathbb{C}$ onto $\mathbb{C}$, the same must be true of $M_1 \circ M_2$. A formula for $M_1 \circ M_2(z)$ is

$$\begin{aligned} M_1 \circ M_2(z) &= M_1\left(\frac{z+i}{2z-1}\right) \\ &= \frac{i\left(\frac{z+i}{2z-1}\right)+1}{2\left(\frac{z+i}{2z-1}\right)-2} \\ &= \frac{i(z+i)+(2z-1)}{2(z+i)-2(2z-1)} \\ &= \frac{(2+i)z-2}{-2z+(2+2i)}. \end{aligned}$$

We can check that this formula defines a Möbius transformation by noting that

$$(2+i)(2+2i) - (-2)(-2) = -2+6i \neq 0.$$

Strictly speaking, we should check our convention for the exceptional points separately. For example, by convention $M_2(\infty) = \frac{1}{2}$, so that

$$\begin{aligned} M_1 \circ M_2(\infty) &= M_1\left(\tfrac{1}{2}\right) \\ &= \frac{\frac{1}{2}i+1}{1-2} \\ &= \frac{2+i}{-2}. \end{aligned}$$

This agrees with the value obtained when we apply our convention to the formula for $M_1 \circ M_2$.

Thus $M_1 \circ M_2$ is a Möbius transformation given by

$$M_1 \circ M_2(z) = \frac{(2+i)z - 2}{2z + (2+2i)}. \qquad \square$$

Problem 3 Write down matrices $\mathbf{A}_1$ and $\mathbf{A}_2$ associated with the Möbius transformations M_1 and M_2 defined in Example 2. Calculate the product $\mathbf{A}_1\mathbf{A}_2$, and compare it with the Möbius transformation $M_1 \circ M_2$.

In Example 2, the composite of two Möbius transformations M_1 and M_2 turned out to be another Möbius transformation. The solution to Problem 3 demonstrates that the product of matrices associated with M_1 and M_2 is a matrix associated with $M_1 \circ M_2$. The following theorem confirms that this is always the case.

Theorem 6 Composition of Möbius Transformations

Let M_1 and M_2 be Möbius transformations with associated matrices $\mathbf{A}_1$ and $\mathbf{A}_2$, respectively. Then $M_1 \circ M_2$ is a Möbius transformation with an associated matrix $\mathbf{A}_1\mathbf{A}_2$.

Proof Let M_1 and M_2 be defined by

$$M_1(z) = \frac{az+b}{cz+d} \quad \text{and} \quad M_2(z) = \frac{ez+f}{gz+h}.$$

Since M_1 and M_2 are one–one mappings of $\hat{\mathbb{C}}$ onto $\hat{\mathbb{C}}$, the same must be true of $M_1 \circ M_2$. We can obtain a formula for $M_1 \circ M_2(z)$ as follows:

$$\begin{aligned}
M_1 \circ M_2(z) &= M_1\left(\frac{ez+f}{gz+h}\right)\\
&= \frac{a\left(\frac{ez+f}{gz+h}\right) + b}{c\left(\frac{ez+f}{gz+h}\right) + d}\\
&= \frac{a(ez+f) + b(gz+h)}{c(ez+f) + d(gz+h)}\\
&= \frac{(ae+bg)z + (af+bh)}{(ce+dg)z + (cf+dh)}.
\end{aligned}$$

Strictly speaking, we should check the exceptional cases separately. However, we shall omit this checking from here onwards.

Since $M_1 \circ M_2$ is one–one, this formula cannot remain constant as z varies, so $(ae+bg)(cf+dh) - (af+bh)(ce+dg) \neq 0$. The formula must therefore define a Möbius transformation.

A matrix associated with $M_1 \circ M_2$ is

$$\begin{pmatrix} ae+bg & af+bh \\ ce+dg & cf+dh \end{pmatrix},$$

which is the product of the matrices

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix} \quad \text{and} \quad \begin{pmatrix} e & f \\ g & h \end{pmatrix}$$

associated with M_1 and M_2, respectively.

Theorem 6 enables us to calculate the composite of two Möbius transformations by using the following strategy.

Strategy To compose two Möbius transformations M_1 and M_2:

1. write down matrices $\mathbf{A}_1$ and $\mathbf{A}_2$ associated with M_1 and M_2;
2. calculate $\mathbf{A}_1\mathbf{A}_2$;
3. write down the Möbius transformation $M_1 \circ M_2$ with which $\mathbf{A}_1\mathbf{A}_2$ is associated.

Example 3 Use the strategy to determine the composite $M_1 \circ M_2$ of the Möbius transformations

$$M_1(z) = \frac{3z+1}{iz-2} \quad \text{and} \quad M_2(z) = \frac{2iz+3}{z-2}.$$

Solution The Möbius transformations M_1 and M_2 have associated matrices

$$\mathbf{A}_1 = \begin{pmatrix} 3 & 1 \\ i & -2 \end{pmatrix} \quad \text{and} \quad \mathbf{A}_2 = \begin{pmatrix} 2i & 3 \\ 1 & -2 \end{pmatrix},$$

respectively. It follows that a matrix associated with $M_1 \circ M_2$ is

$$\mathbf{A}_1\mathbf{A}_2 = \begin{pmatrix} 3 & 1 \\ i & -2 \end{pmatrix} \begin{pmatrix} 2i & 3 \\ 1 & -2 \end{pmatrix} = \begin{pmatrix} 1+6i & 7 \\ -4 & 4+3i \end{pmatrix}.$$

The composite $M_1 \circ M_2$ is therefore the Möbius transformation defined by

$$M_1 \circ M_2(z) = \frac{(1+6i)z+7}{-4z+(4+3i)}.$$ □

Problem 4 Let M_1 and M_2 be the Möbius transformations defined by

$$M_1(z) = \frac{3z+1}{iz-2} \quad \text{and} \quad M_2(z) = \frac{2iz+3}{z-2}.$$

Use the strategy to determine each of the following composites.

(a) $M_2 \circ M_1$ (b) $M_1 \circ M_1$

Problem 5 Let M_1 and M_2 be the Möbius transformations defined by

$$M_1(z) = \frac{z - i}{iz + 2} \quad \text{and} \quad M_2(z) = \frac{2z + i}{-iz + 1}.$$

Use the strategy to determine the composite $M_1 \circ M_2$.

5.3.6 Inverting Möbius Transformations

In the solution to Problem 5 you saw that the composite $M_1 \circ M_2$ of the Möbius transformations

$$M_1(z) = \frac{z - i}{iz + 2} \quad \text{and} \quad M_2(z) = \frac{2z + i}{-iz + 1}$$

is the identity function on $\mathbb{C}$. This shows that M_2 is the inverse function of M_1. In terms of matrices, this is equivalent to saying that there are matrices associated with M_1 and M_2 whose product is the identity matrix $\mathbf{I}$. For example,

$$\begin{pmatrix} 1 & -i \\ i & 2 \end{pmatrix} \begin{pmatrix} 2 & i \\ -i & 1 \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}.$$

We can use this idea to find the inverse of any given Möbius transformation M. The inverse function M^{-1} certainly exists, since M is a one-one transformation from $\mathbb{C}$ onto $\mathbb{C}$. To find the inverse, let $\mathbf{A}$ be a matrix associated with M. Since $\mathbf{A}$ is invertible,

$$\mathbf{A}\mathbf{A}^{-1} = \mathbf{I} = \mathbf{A}^{-1}\mathbf{A},$$

so the Möbius transformation associated with the matrix $\mathbf{A}^{-1}$ must be the inverse function M^{-1}.

Now, if $M(z) = \frac{az+b}{cz+d}$, we can take $\mathbf{A} = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$, so that

$$\mathbf{A}^{-1} = \frac{1}{ad - bc} \begin{pmatrix} d & -b \\ -c & a \end{pmatrix}.$$

But any non-zero multiple of $\mathbf{A}^{-1}$ is also a matrix associated with M^{-1}, so we shall usually use the matrix $\begin{pmatrix} d & -b \\ -c & a \end{pmatrix}$ as a matrix for M^{-1}. Then

$$M^{-1}(z) = \frac{dz - b}{-cz + a}.$$

We summarize the result of this discussion in the following theorem.

Theorem 7 Inverse of a Möbius Transformation
The inverse of the Möbius transformation

$$M(z) = \frac{az + b}{cz + d}$$

is also a Möbius transformation, and it may be written in the form

$$M^{-1}(z) = \frac{dz - b}{-cz + a}.$$

For example, the inverse of the Möbius transformation

$$M(z) = \frac{iz + 1}{2z - 2}$$

is given by

$$M^{-1}(z) = \frac{-2z - 1}{-2z + i} = \frac{2z + 1}{2z - i}.$$

Problem 6 Determine the inverse of each of the following Möbius transformations.

(a) $M_1(z) = \frac{3iz+2}{z-3i}$ (b) $M_2(z) = \frac{4i}{z}$ (c) $M_3(z) = \frac{4iz}{z-4i}$

5.3.7 The Inversive Group

We now have all the information we need to prove the following theorem.

Theorem 8 The set of all Möbius transformations forms a group under composition of functions.

Proof We show that the four group axioms hold.

G1 CLOSURE By Theorem 6, the composite of two Möbius transformations is itself a Möbius transformation.
G2 IDENTITY The identity is the Möbius transformation given by $M(z) = \frac{1z+0}{0z+1}$.
G3 INVERSES By Theorem 7, every Möbius transformation has an inverse.
G4 ASSOCIATIVITY Composition of functions is always associative.

It follows that the set of all Möbius transformations forms a group under composition of functions.

Having shown that the set of Möbius transformations forms a group, we now investigate its relationship with the group of all inversive transformations. We know from Theorem 4 that every Möbius transformation is an inversive transformation, but is every inversive transformation a Möbius transformation? Clearly, the answer is no. For example, an inversion cannot be a Möbius transformation since it *reverses* the orientation of angles, whereas all Möbius transformations *preserve* the orientation of angles.

Although inversions are not Möbius transformations, there is a close connection between inversions and Möbius transformations.

Theorem 9 Every inversion t has the form $t(z) = M(\bar{z})$, where M is a Möbius transformation.

Proof If t is an inversion of $\mathbb{C}$ in an extended line, then by Theorem 1 of Section 5.2 it must have the form $t(z) = a\bar{z} + b$, with $t(\infty) = \infty$. It follows that $t(z) = M(\bar{z})$, where M is the Möbius transformation

$$M(z) = \frac{az + b}{0z + 1}.$$

It cannot have the form $t(z) = az + b$, since t reverses the orientation of angles.

On the other hand, if t is an inversion of $\mathbb{C}$ in a circle of radius r with centre c, then by Theorem 3 of Section 5.2,

$$t(z) = \frac{r^2}{\overline{z - c}} + c = \frac{r^2 + c(\bar{z} - \bar{c})}{\bar{z} - \bar{c}} = \frac{c\bar{z} + (r^2 - c\bar{c})}{\bar{z} - \bar{c}}.$$

So once again t has the form $t(z) = M(\bar{z})$, where M is the Möbius transformation

$$M(z) = \frac{cz + r^2 - c\bar{c}}{z - \bar{c}}.$$

Notice that

$$c \cdot (-\bar{c}) - (r^2 - c\bar{c}) \cdot 1 = -r^2 \neq 0.$$

We can now show that every inversive transformation t has the form $t(z) = M(z)$ or $t(z) = M(\bar{z})$, where M is a Möbius transformation.

Theorem 10 Every inversive transformation t can be represented in $\mathbb{C}$ by one of the formulas

$$t(z) = \frac{az + b}{cz + d} \quad \text{or} \quad t(z) = \frac{a\bar{z} + b}{c\bar{z} + d},$$

where $a, b, c, d \in \mathbb{C}$ and $ad - bc \neq 0$.

Proof We first show that the composite of two inversions t_1 and t_2 is a Möbius transformation. By Theorem 9 above, we can write $t_1(z) = M_1(\bar{z})$ and $t_2(z) = M_2(\bar{z})$, where M_1 and M_2 are Möbius transformations. Thus

$$t_1 \circ t_2(z) = t_1(M_2(\bar{z})) = M_1(\overline{M_2(\bar{z})}).$$

But if

$$M_2(z) = \frac{az + b}{cz + d},$$

then we can define a Möbius transformation M_3 by

$$M_3(z) = \overline{M_2(\bar{z})} = \overline{\frac{a\bar{z} + b}{c\bar{z} + d}} = \frac{\bar{a}z + \bar{b}}{\bar{c}z + \bar{d}}.$$

Since $t_1 \circ t_2(z) = M_1(\overline{M_2(\bar{z})}) = M_1(M_3(z))$, it follows that $t_1 \circ t_2$ is a composite of two Möbius transformations, and is therefore a Möbius transformation.

Next, let t be an arbitrary inversive transformation, and write

$$t = t_1 \circ t_2 \circ \ldots \circ t_n,$$

where $t_1, t_2, \ldots, t_n$ are inversions. If n is even, then we can rewrite t as a composite of Möbius transformations by pairing together the inversions in the form

$$t = (t_1 \circ t_2) \circ (t_3 \circ t_4) \circ \ldots \circ (t_{n-1} \circ t_n).$$

It follows that t is a Möbius transformation, M say, so we can write $t(z) = M(z)$.

To deal with the case where n is odd, let r be the extended conjugation function. Since r is its own inverse, we can write

$$t = (t_1 \circ t_2 \circ \ldots \circ t_n \circ r) \circ r.$$

Here the composite in the bracket involves an even number of inversions, so it must be a Möbius transformation, M say. Hence $t(z) = M \circ r(z) = M(\bar{z})$.

Theorem 10 provides us with an insight into the structure of the group G of all inversive transformations. Those inversive transformations that can be written in the form

$$t(z) = \frac{az + b}{cz + d}$$

are Möbius transformations, and we know from Theorem 8 that they form a subgroup of G. We refer to these transformations as **direct** inversive transformations because they preserve the orientation of angles.

The remaining inversive transformations are of the form

$$t(z) = \frac{a\bar{z} + b}{c\bar{z} + d}.$$

These are Möbius transformations composed with the extended conjugation function, and so they reverse the orientation of angles. For this reason we shall refer to them as **indirect** inversive transformations.

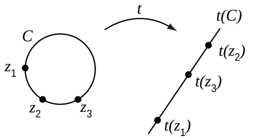
5.3.8 Images of Generalized Circles

We have shown that an inversive transformation maps generalized circles onto generalized circles. However, apart from the special case of inversion in the unit circle, we have not yet given a strategy for finding the image of a generalized circle under an inversive transformation.

One such strategy is based on the fact that every generalized circle in C is uniquely determined by any three points lying on it. Indeed, if the three points lie in C, and are non-collinear, then they determine a unique circle in C. On the other hand, if the three points are collinear, or if one of the points is , then they determine a unique (extended) line.

Strategy To determine the image of a generalized circle C under an inversive transformation t:

1. write down three points z_1, z_2, z_3 on C;
2. determine the images $t(z_1), t(z_2), t(z_3)$;
3. the image $t(C)$ is the (unique) generalized circle through $t(z_1)$, $t(z_2)$, $t(z_3)$.



Example 4 Use the strategy to find the image of the unit circle C under the inversive transformation defined by

$$t(z) = \frac{\bar{z} + i}{\bar{z}\quad 1}.$$

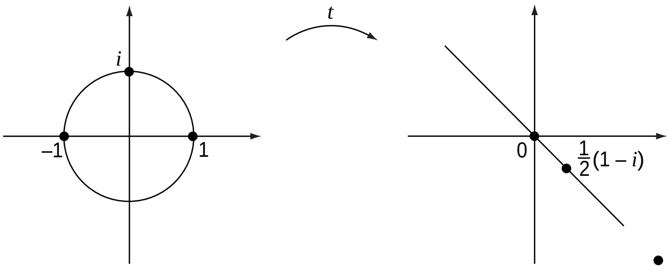
Solution We first pick three distinct points on the unit circle. There is no definite rule about which points should be chosen, so to keep the calculations simple, we pick the points 1, i and 1, as shown below. Now

$$t(1) = \quad,\ t(i) = \frac{\bar{i} + i}{\bar{i}\quad 1} = 0 \quad \text{and}$$

$$t(\quad 1) = \frac{\overline{\quad 1} + i}{\overline{\quad 1}\quad 1} = \frac{1}{2}(1 \quad i).$$

If you can pick a point that maps to then you know immediately that the image is an extended line.

So the image of C is the generalized circle through the points , 0 and $\frac{1}{2}(1 \quad i)$. This is an extended line through the origin with slope 1. □



Problem 7 Let t be the inversive transformation defined by

$$t(z) = \frac{z - 2i}{z + 2}.$$

Use the strategy to determine the image of each of the following generalized circles under t:

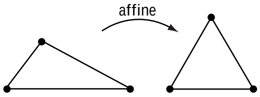
(a) the extended line $L \cup \{\infty\}$, where L is the line with equation $x + y = 2$;
(b) the circle with equation $(x + 1)^2 + y^2 = 1$.

Here $x + iy = z$, as usual.

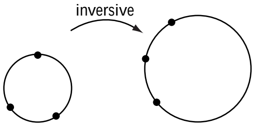
5.4 Fundamental Theorem of Inversive Geometry

5.4.1 Comparison with Affine Geometry

In Subsection 2.3.2 we introduced the Fundamental Theorem of Affine Geometry, which states that, given any three non-collinear points in the plane, there is always an affine transformation that maps the points to another three given non-collinear points. Since a triangle is uniquely determined by its three (non-collinear) vertices, and since affine transformations map triangles to triangles, we were able to use the Fundamental Theorem of Affine Geometry to show that all triangles are affine-congruent.

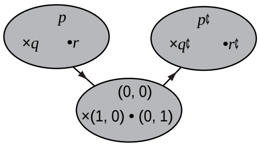


In this section we prove an analogous *Fundamental Theorem of Inversive Geometry* which states that given any three points in the extended complex plane $\hat{\mathbb{C}}$ there is always an inversive transformation (in fact a Möbius transformation) that maps them to another three given points in the extended complex plane. Since a generalized circle is uniquely determined by any three of its points, and since inversive transformations map generalized circles to generalized circles, we can show that all generalized circles are inversive-congruent. That is, given any two generalized circles C_1 and C_2 in the extended plane, it is always possible to find an inversive transformation (in fact a Möbius transformation) that maps C_1 onto C_2.

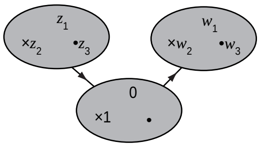


5.4.2 Mapping Three Points to Three Points

The proof of the Fundamental Theorem of Inverse Geometry is very similar to the proof of the Fundamental Theorem of Affine Geometry which we gave in Subsection 2.3.2. There we described how to construct an affine transformation which maps one given set of three (non-collinear) points in $\mathbb{R}^2$ onto another. We did this by forming a composite of two affine transformations which map the points via the auxiliary points (0, 0), (1, 0) and (0, 1).



A similar idea works for the Fundamental Theorem of Inversive Geometry. In this geometry the space is $\hat{\mathbb{C}}$ rather than $\mathbb{R}^2$, and we map via the auxiliary points 0, 1 and ∞.



So let us start by considering how to construct a Möbius transformation that maps three given points z_1, z_2, z_3 in $\hat{\mathbb{C}}$ to the points $0, 1, \infty$, respectively.

First observe that if z_1, z_2, z_3 belong to C, then any Möbius transformation of the form

$$M(z) = K\frac{z \quad z_1}{z \quad z_3}$$

Here K can be any complex number.

maps z_1 to 0 and z_3 to . We can therefore obtain the required Möbius transformation by choosing K so that $M(z_2) = 1$. The following example illustrates how this is done. It also shows how the method can be modified to deal with cases where one of z_1, z_2, z_3 is .

Example 1 For each set of three points given below, determine a Möbius transformation M that maps the points to 0, 1, , respectively.

(a) $\frac{1}{2}$, 1, 3 (b) , i, 2 (c) i, , 3 (d) 5, 2,

Solution

(a) To ensure that $M\ \frac{1}{2}\ = 0$ and $M(3) =$ we let M have the form

$$M(z) = K\frac{z \quad \frac{1}{2}}{z \quad 3},$$

for some complex number K. Since $M(\ \ 1) = 1$, we must have

$$1 = K\frac{1 \quad \frac{1}{2}}{1 \quad 3},$$

This has the form

$$M(z) = \frac{az + b}{cz + d}$$

with $a = K$, $b = \ \ \frac{1}{2}K$, $c = 1$ and $d = \ \ 3$.

so that $K = \frac{8}{3}$. The required Möbius transformation is therefore

$$M(z) = \frac{8z \quad 4}{3z \quad 9}.$$

(b) To ensure that $M(\ \ ) = 0$ and $M(2) =$ we let M have the form

$$M(z) = \frac{K}{z \quad 2}.$$

Since $M(i) = 1$, we must have

$$1 = \frac{K}{i \quad 2},$$

so that $K = i \quad 2$. It follows that

$$M(z) = \frac{i \quad 2}{z \quad 2}.$$

This has the form

$$M(z) = \frac{az + b}{cz + d}$$

with $a = 0$, $b = K$, $c = 1$ and $d = \ \ 2$. Since $c = 0$, it follows from the definition of a Möbius transformation that $M(\ \ ) = a/c = 0$, as required.

(c) To ensure that $M(i) = 0$ and $M(3) =$ we let M have the form

$$M(z) = \frac{z \quad i}{z \quad 3}.$$

In this case there is no need to include a constant K because $M(\ \ )$ is already equal to 1.

This has the form

$$M(z) = \frac{az+b}{cz+d}$$

with $a = 1$, $b = \ \ i$, $c = 1$ and $d = \ \ 3$. Since $c = 0$, we have $M(\ \ ) = a/c = 1$, as required.

(d) Here we require $M(5) = 0$ and $M(\quad) = \quad$, so M is an extended linear function of the form

$$M(z) = K(z \quad 5).$$

Since $M(2) = 1$, we must have

$$1 = K(2 \quad 5),$$

so that $K = \quad \frac{1}{3}$. It follows that

$$M(z) = \quad \frac{1}{3}(z \quad 5). \qquad \square$$

This has the form

$$M(z) = \frac{az+b}{cz+d}$$

with $a = K$, $b = \quad 5K$, $c = 0$ and $d = 1$. Since $c = 0$, it follows from the definition of a Möbius transformation that $M(\quad) = \quad$.

Guided by the above example we can summarize all the possible cases to obtain the following general strategy.

Strategy To determine the Möbius transformation M which maps three given points z_1, z_2, z_3 onto the points $0, 1, \quad$ respectively:

1. choose the appropriate form of mapping from the following formulas for M:
   for $z_1, z_2, z_3 \quad 0, 1, \quad$ use $M(z) = K\frac{z \quad z_1}{z \quad z_3}$;
   for $\quad, z_2, z_3 \quad 0, 1, \quad$ use $M(z) = \frac{K}{z \quad z_3}$;
   for $z_1, \quad, z_3 \quad 0, 1, \quad$ use $M(z) = \frac{z \quad z_1}{z \quad z_3}$;
   for $z_1, z_2, \quad 0, 1, \quad$ use $M(z) = K(z \quad z_1)$;
2. find the complex number K for which $M(z_2) = 1$.

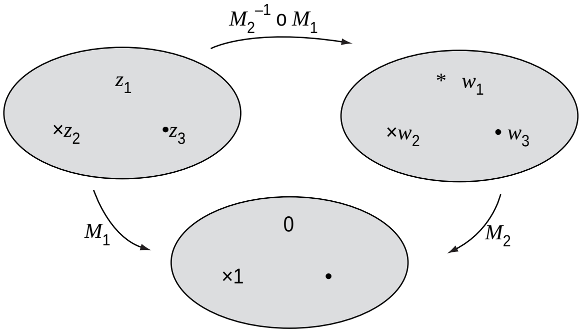
Problem 1 For each set of three points given below, determine a Möbius transformation M that maps the points to $0, 1, \quad$, respectively.

(a) $\quad 1, \quad 3, 0$ (b) $\frac{3}{2}, 2, 1$ (c) $\quad, \quad 3, 2$ (d) $\frac{3}{2}, 2, \quad$

We are now in a position to prove the main theorem of this section.

Theorem 1 The Fundamental Theorem of Inversive Geometry
Let z_1, z_2, z_3 and w_1, w_2, w_3 be two sets of three points in the extended complex plane C. Then there is a unique Möbius transformation M which maps z_1 to w_1, z_2 to w_2, and z_3 to w_3.

Proof According to the above strategy there is a Möbius transformation M_1 which maps the points z_1, z_2, z_3 to the points $0, 1, \quad$, respectively. Similarly, there is a Möbius transformation M_2 which maps the points w_1, w_2, w_3 to the points $0, 1, \quad$, respectively.



$M_2^{-1} \circ M_1$
z_1
$\times z_2$
$\bullet z_3$
$*$ w_1
$\times w_2$
$\bullet w_3$
M_1
0
$\times 1$
M_2

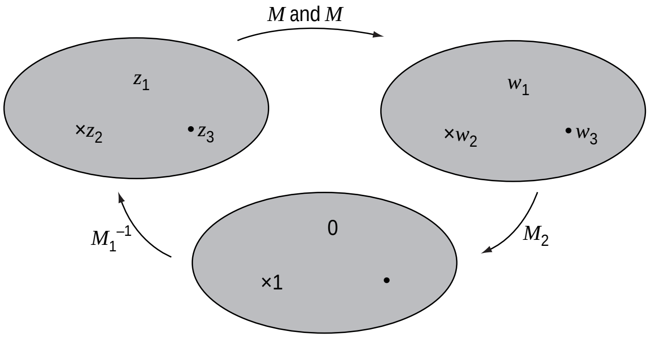
The composite $M = M_2^{-1} \circ M_1$ is therefore the required Möbius transformation which maps z_1, z_2, z_3 to the points w_1, w_2, w_3, respectively.

To check uniqueness we first observe that the identity is the only Möbius transformation which maps each of the points $0, 1, \infty$ to themselves. Indeed, if

$$M(z) = \frac{az + b}{cz + d}$$

is a Möbius transformation which maps ∞ to itself, then $c = 0$. Also, if M maps 0 to itself, then $M(0) = b/d = 0$, so $b = 0$. It follows that $M(z) = (a/d)z$. But if M maps 1 to itself, then $M(1) = a/d = 1$, which implies that $a = d$. Putting all this together we conclude that M is the identity $M(z) = z$, as required.

Next suppose that M and M' are two Möbius transformations which satisfy the conditions of the theorem.



M and M'
z_1
$\times z_2$
$\bullet z_3$
w_1
$\times w_2$
$\bullet w_3$
M_1^{-1}
0
$\times 1$
M_2

Then the composites $M_2 \circ M \circ M_1^{-1}$ and $M_2 \circ M' \circ M_1^{-1}$ must both be Möbius transformations which map each of the points $0, 1, \infty$ to themselves. Since this implies that both composites are equal to the identity, we can write

$$M_2 \circ M \circ M_1^{-1} = M_2 \circ M' \circ M_1^{-1}.$$

If we now compose both sides of this equation with M_2^{-1} on the left and with M_1 on the right, then we obtain $M = M'$, as required.

If we actually need to find the Möbius transformation which maps one set of three points onto another set of three points we simply follow the strategy used to prove part (a) of the Fundamental Theorem.

Strategy To determine the Möbius transformation M which maps the points z_1, z_2, z_3 to the points w_1, w_2, w_3, respectively:

1. find the Möbius transformation M_1 which maps the points z_1, z_2, z_3 to the points 0, 1, , respectively;
2. find the Möbius transformation M_2 which maps the points w_1, w_2, w_3 to the points 0, 1, , respectively;
3. calculate $M = M_2^{\ 1} \quad M_1$.

The following example illustrates how to implement this strategy.

Example 2 Find the Möbius transformation M which maps the points i, , 3 to the points $\frac{1}{2}$, 1, 3, respectively.

Solution We follow the steps in the above strategy.

1. From part (c) of Example 1, we know that the Möbius transformation M_1 which maps the points i, , 3 to the points 0, 1, , respectively, is given by

$$M_1(z) = \frac{z \quad i}{z \quad 3}.$$

2. Also, from part (a) of Example 1, we know that the Möbius transformation M_2 which maps the points $\frac{1}{2}$, 1, 3 to the points 0, 1, , respectively, is given by

$$M_2(z) = \frac{8z \quad 4}{3z \quad 9}.$$

3. Matrices associated with M_1 and M_2 are

$$\begin{matrix} 1 & i \\ 1 & 3 \end{matrix} \quad \text{and} \quad \begin{matrix} 8 & 4 \\ 3 & 9 \end{matrix} \ ;$$

also, by Theorem 7 of Subsection 5.3.6, a matrix associated with the inverse of M_2 is

$$\begin{matrix} 9 & 4 \\ 3 & 8 \end{matrix} \ .$$

Hence, a matrix associated with $M = M_2^{\ l} \quad M_1$ is given by

$$\begin{matrix} 9 & 4 \\ 3 & 8 \end{matrix} \quad \begin{matrix} 1 & i \\ 1 & 3 \end{matrix} = \begin{matrix} 5 & 12 + 9i \\ 5 & 24 + 3i \end{matrix} \ .$$

The required Möbius transformation is therefore

$$M(z) = \frac{-5z - 12 + 9i}{5z - 24 + 3i}. \qquad \square$$

As a check, you can verify that $M(i) = \frac{1}{2}$, $M(\infty) = -1$ and $M(3) = 3$.

Problem 2

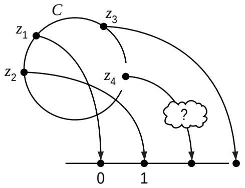
(a) Find the Möbius transformation which maps the points $-1, i, 1$ to the points $-1, -3, 0$, respectively.

(b) Find the Möbius transformation which maps the points $3, \infty, -2$ to the points $3, \frac{7}{3}, 1$, respectively.

5.4.3 Circles through Four Points

We now explore an application of the Fundamental Theorem which enables us to determine whether four given points z_1, z_2, z_3 and z_4 lie on some generalized circle.

If there is a generalized circle that passes through z_1, z_2, z_3 and z_4, then it must be the unique generalized circle C that passes through z_1, z_2 and z_3. We have to decide whether C also passes through z_4. To do this, consider the Möbius transformation M that maps z_1, z_2, z_3 to $0, 1, \infty$, respectively. Under M the image of C is the extended real axis, for this is the only generalized circle that passes through 0, 1 and ∞. If z_4 lies on C, then its image under M must lie on the real axis; whereas if z_4 does not lie on C, then its image under M cannot lie on the real axis.



Example 3 Determine whether the four points i, $1 + 4i$, 3, $4 + 3i$ lie on a generalized circle.

Solution First, we determine the Möbius transformation M that maps i, $1 + 4i$, 3 to $0, 1, \infty$, respectively. Following the strategy in the previous subsection, we observe that this transformation must be of the form

$$M(z) = K\frac{z - i}{z - 3}$$

for some complex number K. Since $M(1 + 4i) = 1$, we must have

$$1 = K\frac{(1 + 4i) - i}{(1 + 4i) - 3} = K\frac{1 + 3i}{-2 + 4i},$$

so

$$K = \frac{-2 + 4i}{1 + 3i} = \frac{(-2 + 4i)(1 - 3i)}{10} = 1 + i.$$

You met this method of simplifying a quotient by multiplying both numerator and denominator by the conjugate of the denominator earlier, in Subsection 5.2.1.

Thus the transformation M is given by

$$M(z) = \frac{(z - i)(1 + i)}{z - 3}.$$

It follows that

$$M(4+3i)=\frac{(4+2i)(1+i)}{1+3i}=\frac{2+6i}{1+3i}=2.$$

Since this is real, it follows that i, $1+4i$, 3, $4+3i$ do all lie on a generalized circle. □

In this example we showed that the points i, $1+4i$, 3, $4+3i$ all lie on a generalized circle; but suppose we want to show that the points lie on an *ordinary* circle. To do this we need to check that the generalized circle that passes through the points is not an extended line. If it were an extended line, then it would pass through , and so $M(\ \ )$ would be real. Since $M(\ \ )=1+i$ is not real, it follows that the points do indeed lie on an ordinary circle.

$M(\ \ )$ cannot be , as M is one one and $M(3)=$.

Strategy To determine whether z_1, z_2, z_3 and z_4 lie on a circle:

1. find the Möbius transformation M which maps z_1, z_2, z_3 to 0, 1, , respectively;
2. the points z_1, z_2, z_3, z_4, lie on a generalized circle if and only if $M(z_4)$ is real;
3. the generalized circle in Step 2 is a circle provided that $M(\ \ )$ is not real.

If $M(z_4)$ and $M(\ \ )$ are both real, then z_1, z_2, z_3, z_4 lie on a line.

Problem 3 Determine whether each of the following sets of four points lies on a circle.

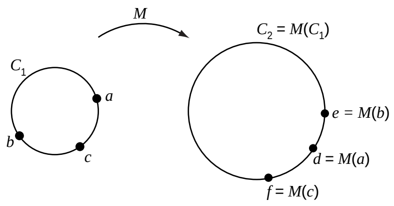
(a) 0, 4, 2i, 1 3i (b) 1, i, i, 2 i

5.4.4 Congruence of Generalized Circles

We end this section by stating an important consequence of the Fundamental Theorem of Inversive Geometry.

Theorem 2 Let C_1 and C_2 be generalized circles in the extended complex plane. Then there is a Möbius transformation that maps C_1 onto C_2.

Proof Let a, b, c be any three points on C_1 and let d, e, f be any three points on C_2. By the Fundamental Theorem of Inversive Geometry, there is a Möbius transformation M that maps a, b, c to d, e, f, respectively.



Since M maps generalized circles to generalized circles, it must map C_1 to a generalized circle through d, e and f. But a generalized circle is uniquely determined by any three of its points, so C_2 is the only generalized circle that passes through d, e and f. It follows that M maps C_1 onto C_2.

One of the remarkable consequences of Theorem 2 is that all generalized circles are inversive-congruent. In particular, an ordinary circle is inversive-congruent to any given (extended) line. Since lines are often easier to investigate than circles, we can sometimes simplify a problem that involves the inversive properties of a figure by using an inversive transformation to map one or more of the circles in a figure onto (extended) lines. You will see several examples of this in the next section.

5.5 Coaxal Families of Circles

We now prove some lovely theorems about circles, where the beauty of the final results is matched by the beauty of the proofs themselves. Inversion is our key tool.

Sadly this is not always the case in Mathematics!

5.5.1 Apollonian Circles Theorem

We start with the proof of the Apollonian Circles Theorem, which we stated at the beginning of the chapter.

Theorem 1 Apollonian Circles Theorem
Let A and B be two distinct points in the plane, and let k be a positive real number other than 1. Then the locus of points P that satisfy $PA : PB = k : 1$ is a circle whose centre lies on the line through A and B.

Recall that if $k = 1$, then P must lie on the perpendicular bisector of AB.

We give two proofs of this result. The first uses methods from Euclidean geometry, and has the advantage of providing us with equations for the circles in terms of k. The second proof uses the methods of inversive geometry, and has the advantage of providing us with a deeper insight into the geometry of the circles.

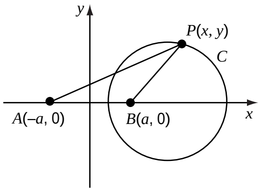
The second proof is given later.

First Proof

To keep the algebra simple, we introduce x- and y-axes into the plane such that A and B have coordinates $(-a, 0)$ and $(a, 0)$, respectively, where $a > 0$.

Now fix a value of $k > 0$, $k \neq 1$, and let C be the locus of points P that satisfy $PA : PB = k : 1$. Then a point $P(x, y)$ belongs to C if and only if $PA = k \bullet PB$, and since $k > 0$ this is equivalent to the equation

$$PA^2 = k^2 \bullet PB^2.$$



Using the Euclidean formula for distance between points, we see that this last equation holds if and only if

$$(x + a)^2 + y^2 = k^2((x - a)^2 + y^2).$$

Multiplying out the brackets and collecting terms in x^2, y^2 and x, we see that this is equivalent to

$$x^2(1 \quad k^2) + y^2(1 \quad k^2) + 2ax\,(1 + k^2) + a^2(1 \quad k^2) = 0.$$

Since $k = 1$, this holds if and only if

$$x^2 + y^2 + 2a \quad \frac{1 + k^2}{1 \quad k^2} \quad x + a^2 = 0.$$

It follows that the locus C is a circle with centre c and radius r where

$$c = \quad a \quad \frac{1 + k^2}{1 \quad k^2} \quad , 0$$

and

$$r = \overline{\quad a^2 \quad \frac{1 + k^2}{1 \quad k^2}^{\,2} \quad a^2} = \frac{2ak}{|1 \quad k^2|}.$$

Here we are using the formulas for centre and radius given in Theorem 2, Subsection 1.1.2.

In particular, the centre lies on the x-axis, which by our choice of axes is the line through A and B.

Notice that the centre of the circle is *not* at either of the points A or B.

If $k = 1$, then the locus of points that satisfy $PA = k \bullet PB$ is the line that bisects AB at right angles. If we adopt the convention that this locus includes the point , then we can think of this locus as the extended line $\{ \}$. With this convention, every positive value of k gives rise to a generalized circle known as a **circle of Apollonius**. The family of all such circles is known as the **Apollonian family of circles** defined by the points A and B.

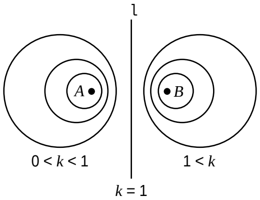
A circle of Apollonius is often referred to as an Apollonian circle .

As k increases through the interval $(0, \quad)$, the corresponding circles range through the Apollonian family.

When $0 < k < 1$, we have that $PA < PB$, and so P is closer to A than it is to B. The circles that correspond to these values of k therefore lie on the same side of as does A. For values of k close to 0, $PA = k \bullet PB$ is small, and so the corresponding circles are close to A. As k tends to 1, the circles grow and become ever closer to .

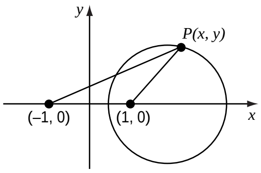
When $k = 1$, the corresponding circle is the extended line $\{ \}$.

When $k > 1$, we have that $PA > PB$, so that P is closer to B than it is to A. The circles that correspond to these values of k therefore lie on the same side of as does B. As k increases from 1, $PB = (1/k) \bullet PA$ becomes smaller, and the corresponding circles shrink and become ever closer to B.



In light of the above discussion, it is sometimes convenient to refer to the points A and B as **point circles** corresponding to the cases $k = 0$ and $k = \quad$, respectively. With this convention, every point of the plane belongs to a unique circle associated with the Apollonian family.

Example 1 For the Apollonian family defined by the point circles $(\quad 1, 0)$ and $(1, 0)$, determine the equation of the circle in the family that passes through the point $(2, 1)$.



Solution Let P be a point (x, y) in the plane whose distance from the point $(-1, 0)$ is k times its distance from the point $(1, 0)$. Then, if we use the Euclidean formula for distance between points in the plane, we obtain

$$(x+1)^2 + y^2 = k^2((x-1)^2 + y^2).$$

For each value of k this yields an equation for the corresponding Apollonian circle. The point $(2, 1)$ lies on the Apollonian circle for which

$$(2+1)^2 + 1^2 = k^2((2-1)^2 + 1^2),$$

that is, $k = \sqrt{5}$.

The equation of the Apollonian circle through the point $(2, 1)$ is therefore

$$(x+1)^2 + y^2 = 5((x-1)^2 + y^2),$$

which simplifies to

$$x^2 + y^2 - 3x + 1 = 0. \qquad \square$$

Problem 1 For the Apollonian family defined by the point circles $(0, -1)$ and $(0, 2)$, determine the equation of the circle in the family that passes through the point $(1, 1)$.

Problem 2 The circles C_1 and C_2 in an Apollonian family of circles have the segments $[-18, -2]$ and $[3, 12]$, respectively, as diameter. Determine the point circles in the family, and hence the equation of the Apollonian circle in the family that passes through the point $(6, 9)$.

We now give a second proof of the Apollonian Circles Theorem, using inversive geometry.

Theorem 1 Apollonian Circles Theorem
Let A and B be two given points in the plane, and let k be a positive real number other than 1. Then the locus of points P that satisfy $PA : PB = k : 1$ is a circle whose centre lies on the line through A and B.

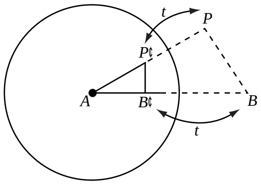
Second Proof

Let C be the locus of points P that satisfy $PA = k \cdot PB$, and let t be the inversion in the circle with centre A and radius 1. We shall show that $C' = t(C)$ is a circle, and hence that $C = t^{-1}(C')$ is a generalized circle.

We specify radius 1 here simply for definiteness; any positive radius would serve equally well.

Let P be an arbitrary point in the extended plane, and let $t(B) = B'$, $t(P) = P'$. Then by the definition of inversion,

$$AB \cdot AB' = 1 \quad \text{and} \quad AP \cdot AP' = 1, \tag{1}$$



so that

$$\frac{AB}{AP} = \frac{AP}{AB}.$$

This shows that the sides AB and AP of APB are proportional to the sides AP and AB of $AB\ P$. Since BAP is the same as $P\ AB$, it follows that APB is similar to $AB\ P$. Hence

$$\frac{B\ P}{PB} = \frac{AP}{AB}.$$

But, from equation (1), $AP = 1/AP$, so P is related to P by the equation

$$B\ P = \frac{PB}{AB \bullet AP}. \qquad (2)$$

Now if P lies on the locus C, then $AP\ (= PA) = k \bullet PB$, so that

$$B\ P = \frac{1}{k \bullet AB}.$$

Thus P lies on a circle C of radius $1/(k \bullet AB)$ and with centre B.

Conversely, if P lies on C, then $B\ P = 1/(k \bullet AB)$, so from equation (2),

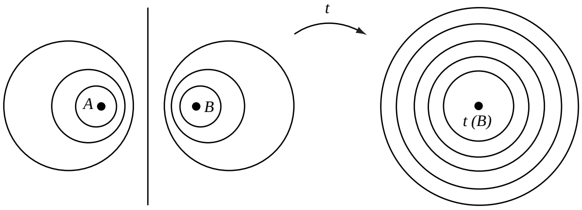
$$\frac{1}{k \bullet AB} = \frac{PB}{AB \bullet AP}.$$

Thus $AP = k \bullet PB$, and so P lies on the locus C.

It follows that the inversion t maps the locus C onto the circle C. But $t^{\ 1} = t$ maps generalized circles to generalized circles, so $C = t^{\ 1}(C)$ is a generalized circle.

This proof sets up a one one correspondence between the family of Apollonian circles and a family of concentric circles. Each Apollonian circle corresponds to a value of k, and this in turn corresponds to a circle of radius $1/(k \bullet AB)$ with centre $B = t(B)$.

In particular, the extended line in the Apollonian family corresponds to $k = 1$, which corresponds to the circle of radius $l/AB = AB$, with centre B. As you would expect, this circle passes through the centre A of the inversion t.



The importance of this correspondence is that it enables us to characterize Apollonian families of circles in terms of inversive transformations. Such a characterization is ideal for tackling problems in inversive geometry so we state it in the form of a theorem.

Theorem 2 Let A and B be distinct points in the plane, and let t be the inversion in the circle with centre A and radius 1. Then the Apollonian family of circles defined by the point circles A and B is mapped by t to the family of all concentric circles with centre $t(B)$; and the family of all concentric circles with centre $t(B)$ is mapped by t to the Apollonian family of circles defined by the point circles A and B.

For t is self-inverse.

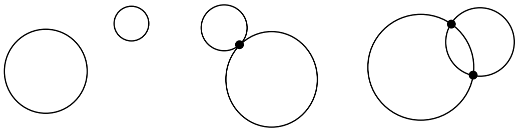
A remarkable consequence of this theorem is that in inversive geometry all Apollonian and concentric families of circles are congruent to each other. Indeed the theorem shows that every Apollonian family of circles is congruent to a family of concentric circles, so it is sufficient to show that all families of concentric circles are congruent to each other. This is easily achieved by noting that any family of concentric circles can be mapped onto any other family of concentric circles by a translation that makes their centres coincide.

Recall that a translation is an inversive transformation provided we adopt the convention that maps to .

5.5.2 Families of Circles

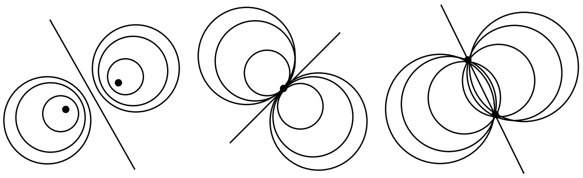
Any two (distinct) generalized circles in the extended plane are related in precisely one of the following ways:

1. they may not intersect;
2. they may intersect in precisely *one* point;
3. they may intersect in *two* distinct points.



Case 1 Case 2 Case 3

In the previous subsection you met Apollonian families of circles, in which no two circles intersect; in the following subsection we will show that any two non-intersecting circles determine an Apollonian family of circles. We now consider the two other families, namely families of generalized circles that intersect at precisely one point and families of generalized circles that intersect at precisely two points.



Apollonian circles Circles through one point Circles through two points

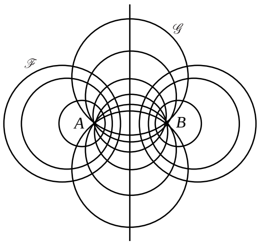
Each of these three families contains precisely one extended line known as the *radical axis* of the family. The centres of the circles in each family lie on a line, or *axis*, that is perpendicular to the radical axis. Since all the circles in each family are symmetrical about the axis through their centres, the families are known as *coaxal families*.

Definition A **coaxal family of circles** in the plane is a family of (generalized) circles of one of the following types:

1. an Apollonian family, with particular point circles;
2. a family that intersect at one particular point;
3. a family that intersect at two particular points.

The extended line in each family is called the **radical axis** of the family.

Given the Apollonian family of circles F defined by point circles A and B, there is a corresponding coaxal family of circles G that pass through A and B. Conversely, given a coaxal family of circles G that pass through distinct points A and B, there is a corresponding Apollonian family of circles F defined by the point circles A and B.

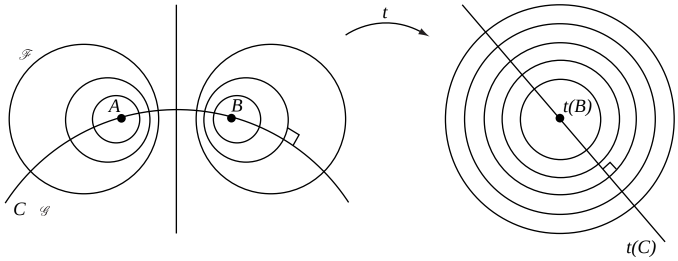


The following theorem describes a remarkable relationship between the two families of circles, F and G.

Theorem 3 Coaxal Circles Theorem
Let A and B be distinct points in the plane. Let F be the Apollonian family defined by the point circles A and B, and let G be the family of all generalized circles through A and B. Then every member of F is orthogonal to every member of G.

Two circles are *orthogonal* if they meet at right angles.

Proof Let t be the inversion in the unit circle with centre A. By Theorem 2, the Apollonian family F is mapped by t to the family of concentric circles with centre $t(B)$.



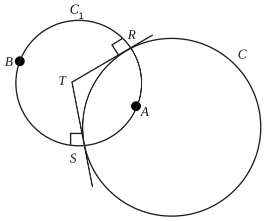
Now let C be an arbitrary member of G. Since C is a generalized circle that passes through A and B, it follows that $t(C)$ is a generalized circle that passes through $t(A) =$ and $t(B)$. In other words, $t(C)$ is an extended line through $t(B)$. Clearly, this line $t(C)$ intersects each of the circles with centre $t(B)$ at right angles. Since inversion preserves the magnitude of angles, it follows that C meets each of the Apollonian circles in F at right angles.

For an Apollonian family of circles defined by point circles A and B, the Coaxal Circles Theorem states that every generalized circle through A and B meets each of the Apollonian circles at right angles. The next theorem enables us to use this fact to deduce that A and B are inverse points with respect to each of the Apollonian circles.

Theorem 4 Two points A and B in the extended complex plane are inverse points with respect to a generalized circle C if and only if every generalized circle through A and B meets C at right angles.

Proof We first show that A and B are inverse points if every generalized circle through A and B meets C at right angles.

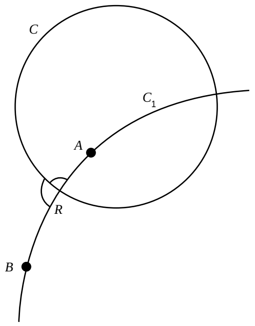
Let C_1 be any generalized circle through A and B that meets C at right angles, at points R and S. Now invert the figure C_1 in the generalized circle C. Since R and S remain fixed, C_1 is mapped to a generalized circle that meets C at right angles at R and S. It follows that C_1 is mapped to itself; for the fact that the image passes through R and S means that it must be a circle, and the radii of this circle through R and S must be along the tangents to C at R and S.



In fact, by a similar argument, every generalized circle through A and B that meets C at right angles maps to itself. The only way this can happen is if A inverts to B, and vice versa. Hence A and B are inverse points.

Next we show that if A and B are inverse points, then every generalized circle through A and B meets C at right angles.

Let A and B be inverse points, and let C_1 be a generalized circle through A and B that meets C at R. Under inversion in C, the points A and B swap over and R remains fixed, so C_1 maps to itself. It follows that both the angles that C_1 makes with the circle C must be equal. These angles must therefore be right angles, which is what we want to prove.



Theorem 4 has two important corollaries. The first follows directly from the Coaxal Circles Theorem.

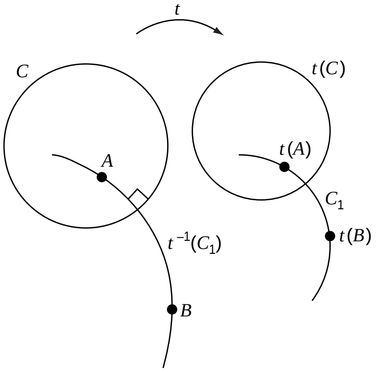
Corollary 1 If C is an Apollonian circle defined by the point circles A and B, then A and B are inverse points with respect to C.

Proof Let C be an Apollonian circle with respect to the point circles A and B. Then by the Coaxal Circles Theorem, every generalized circle through A and B meets C at right angles. By Theorem 4, A and B are inverse points with respect to C.

The second corollary asserts that inverse points are preserved by inversive transformations.

Corollary 2 Let A and B be inverse points with respect to a generalized circle C, and let t be an inversive transformation. Then $t(A)$ and $t(B)$ are inverse points with respect to the generalized circle $t(C)$.

Proof



Let C_1 be an arbitrary generalized circle through $t(A)$ and $t(B)$. Then $t^{-1}(C_1)$ is a generalized circle that passes through A and B. By Theorem 4, $t^{-1}(C_1)$ meets C at right angles. But t preserves the magnitude of angles, so C_1 meets $t(C)$ at right angles. Since C_1 is an arbitrary generalized circle through $t(A)$ and $t(B)$, it follows from Theorem 4 that $t(A)$ and $t(B)$ are inverse points with respect to $t(C)$.

An immediate consequence of Corollary 2 is that if F is the family of *all* generalized circles that have two given points A and B as inverse points, then under an inversive transformation t the family F maps onto the family of *all* generalized circles that have $t(A)$ and $t(B)$ as inverse points.

At first sight this observation appears to be little more than a restatement of Corollary 2; however the restatement has a particular significance, as the following theorem shows.

Theorem 5 Let F be the family of all generalized circles that have A and B as inverse points. Then F is either a concentric family of circles with centres A or B, or the Apollonian family of circles with point circles A and B.

Proof First, suppose that either A or B is the point ; to be definite, assume $A =$. Then each circle in F has and B as inverse points. But this can happen only if B is the centre of each circle in F; in other words F is the family of concentric circles with centre B. A similar argument applies if $B =$.

Next suppose that neither A nor B is the point , and let t be the inversion in the circle of unit radius with centre A. By Theorem 2, t maps the family F to the family of all generalized circles with inverse points at $t(A) =$ and $t(B)$, namely the family of concentric circles with centre $t(B)$. By Theorem 5, F is the Apollonian family of circles defined by the point circles A and B.

Roughly speaking, you can think of the family of concentric circles with centre A as an Apollonian family of circles defined by point circles A and . Then an Apollonian family of circles defined by the point circles A and B maps to an Apollonian family of circles defined by the point circles $t(A)$ and $t(B)$.

In light of the remarks that precede this theorem, it follows that under an inversive transformation t an Apollonian family of circles defined by point circles A and B

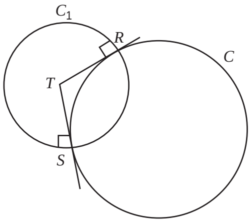
EITHER maps to an Apollonian family of circles defined by the point circles $t(A)$ and $t(B)$,
OR maps to a concentric family of circles with centre $t(A)$ or $t(B)$.

Similarly a concentric family of circles with centre A either maps to the Apollonian family of circles defined by the point circles $t(A)$ and $t(\ )$, or it maps to a concentric family of circles with centre $t(A)$ or $t(\ )$.

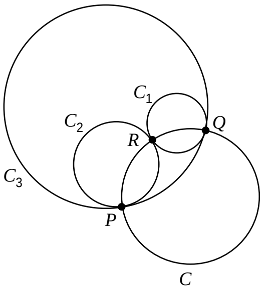
So far, we have used inversive geometry to prove results about Apollonian families of circles, but similar methods can be used to prove results about other plane figures. The technique is to use an inversive transformation (often an inversion) to map one or more circles in the figure to extended straight lines. The additional symmetry that results from this transformation is then used to establish the required result.

For future reference, we also note here a fact that we met in the proof of Theorem 4 above.

Corollary 3 Let C and C_1 be circles that meet at right angles at two points R and S. Then the centre of C_1 is the point T of intersection of the tangents to C at R and S; and C_1 maps to itself under inversion in C.

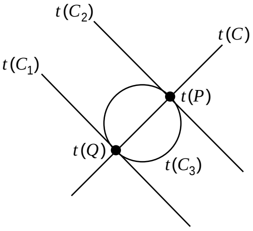


Example 2 Let C_1, C_2 and C_3 be circles in the plane such that C_2 and C_3 touch at a point P, C_1 and C_3 touch at a point Q, and C_1 and C_2 touch at a point R. Let C be the circle that passes through P, Q and R. Prove that C cuts C_1, C_2 and C_3 at right angles.



Solution Let t be an inversion in a circle with centre R. Then $t(C_1)$ and $t(C_2)$ are straight lines. Moreover, since C_1 and C_2 do not meet at any point other than P, it follows that $t(C_1)$ and $t(C_2)$ cannot meet in $\mathbb{C}$ and must therefore be parallel.

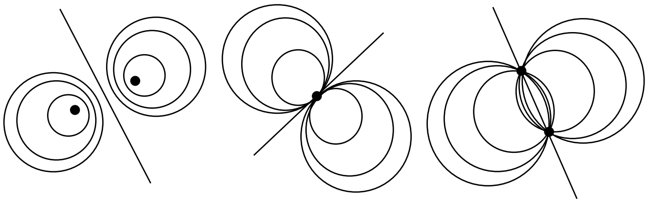
Now C_3 is tangential to C_1 and C_2, and does not pass through R, so $t(C_3)$ must be a circle that touches $t(C_1)$ and $t(C_2)$ tangentially at $t(Q)$ and $t(P)$, respectively. Next observe that C passes through R, so $t(C)$ is the extended line through $t(Q)$ and $t(P)$. Since the transformed figure has reflectional symmetry about $t(C)$, it follows that $t(C)$ cuts $t(C_1)$, $t(C_2)$ and $t(C_3)$ at right angles at $t(P)$ and $t(Q)$. But t preserves angles, so C cuts C_1, C_2 and C_3 at right angles at P and Q.



A similar argument with t replaced by inversion in a circle with centre P (or Q) shows that C cuts C_1 and C_2 at right angles at R. □

5.5.3 Two Circles Determine a Coaxal Family

It is clear that if we are given two circles in a coaxal family of mutually tangential circles, this determines the whole family.

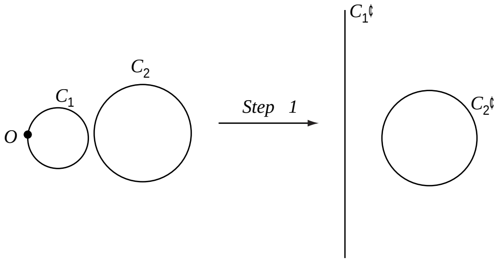


Similarly if we are given two circles in a coaxal family of circles through two fixed points, this determines the whole family. This raises the question as to whether two circles in an Apollonian family are sufficient to determine the whole family. We now prove that this is indeed the case. The crucial tool that we need is the following result.

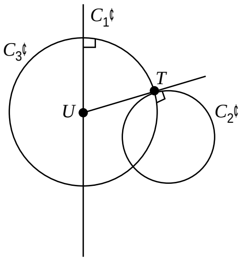
Theorem 6 The Concentricity Theorem
Let C_1 and C_2 be any two non-intersecting circles in the plane. Then there is a inversive transformation that maps C_1 and C_2 onto a pair of concentric circles.

Proof If the circles are concentric then there is nothing to prove, so we may assume they are not concentric.

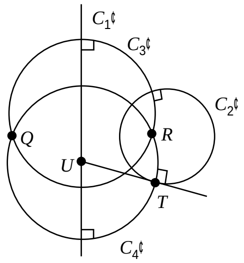
Step 1 Pick a point O on the circle C_1, and invert both circles in the circle of unit radius with centre O. Under this inversion C_1 maps to a line, C_1, and C_2 maps to a circle, C_2.



Step 2 Pick a point T on C_2 that does not lie on the perpendicular from the centre of C_2 to the line C_1, and let the tangent to C_2 at T intersect C_1 at the point U, say. Draw the circle C_3 with centre U and radius UT. This circle is perpendicular to C_2 at T, because a tangent to a circle is perpendicular to the radius at the point of contact. The circle C_3 is perpendicular to the line C_1 because its centre lies on the line C_1.



Step 2

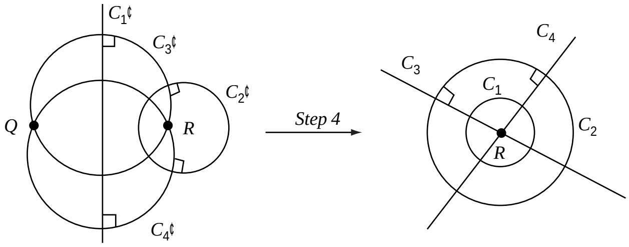


Step 3

Step 3 Repeat the construct in Step 2 starting with another position for the point T, to obtain a circle C_4 perpendicular to both C_1 and C_2 at the respective points T. Let C_3 and C_4 meet at Q and R, say.

Step 4 Invert the figure again, this time in the unit circle with centre Q. Then the line C_1 maps to a circle C_1, and the circle C_2 maps to a circle C_2; the circles C_3 and C_4 pass through Q, so they invert to straight lines at right angles to C_1 and C_2. These lines are therefore diameters of the circles C_1 and C_2, and so the point where they meet (the image R of R) must be the centre of both circles.

As in the (second) proof of Theorem 1, the choice of 1 for the radius is not significant.



Step 5 Composing the inversion in Step 1 with the inversion in Step 4, we obtain an inversive transformation that maps C_1 and C_2 onto the pair of concentric circles C_1 and C_2.

We can now prove the following beautiful result.

Theorem 7 Two Apollonian Circles Theorem

Let C_1 and C_2 be two non-concentric circles that do not intersect. Then there is a unique Apollonian family of circles that contains C_1 and C_2.

Proof By the Concentricity Theorem there is an inversive transformation t that maps C_1 and C_2 onto a pair of concentric circles $t(C_1)$ and $t(C_2)$. Let O be the common centre of these circles, and let G be the family of concentric circles with centre O. Under the inversive transformation t^{1} the family G maps to the family of all generalized circles that have $t^{1}(O)$ and $t^{1}(\ )$ as inverse points; we denote this family by F. Now F cannot be a concentric family of circles, since it contains C_1 and C_2; so, by Theorem 5, it must be an Apollonian family of circles.

Theorem 6 above

To complete the proof we must show that $\mathcal{F}$ is the only Apollonian family of circles that contains C_1 and C_2. To do this suppose that $\mathcal{F}'$ is any Apollonian family of circles that contains C_1 and C_2. Then $\mathcal{F}'$ is mapped by t either to an Apollonian family of circles, or to a concentric family of circles. In fact the image of $\mathcal{F}'$ under t contains the concentric circles $t(C_1)$ and $t(C_2)$ and must therefore be the family $\mathcal{G}$ of concentric circles with centre O. It follows that $\mathcal{F}$ and $\mathcal{F}'$ are the same family of circles, for they are both mapped to $\mathcal{G}$ by t.

5.5.4 Some Applications of Inversion

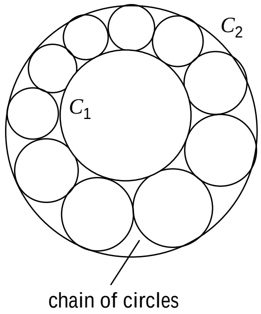
As we mentioned earlier, inversion can often be used to prove results about plane figures, using a suitable inversion to map one or more circles in the figures to extended lines — the additional symmetry then being used to establish the desired result.

Our first application of inversion to prove a beautiful result is known as Steiner's Porism. A *porism* is a mathematical construction problem that has a surprising answer: either the construction cannot be carried out or it has infinitely many solutions.

Jakob Steiner (1796–1863) was a 19th-century Swiss geometer.

Theorem 8 Steiner's Porism
Let C_1 and C_2 be non-intersecting circles, with C_1 inside C_2. Then:

EITHER it is impossible to fit a chain of circles between C_1 and C_2, with each circle touching C_1 and C_2 and two other circles in the chain;
OR it is possible to construct such a chain, and the first circle in the chain can be placed in any convenient position.

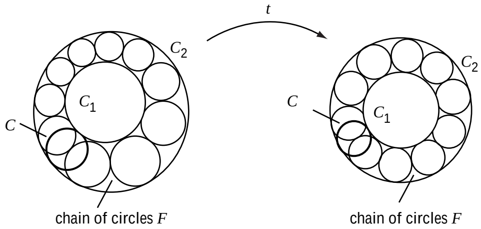


Proof There are two possibilities.

EITHER It is impossible to fit a chain between C_1 and C_2 with the properties described, in which case the porism is established.
OR There is at least one chain F that fits between C_1 and C_2. To establish the porism in this case we must show that a chain also exists for each choice of a first circle C between C_1 and C_2.

By the Concentricity Theorem there is an inversive transformation t that maps C_1 and C_2 onto concentric circles C_1' and C_2'. Under t the chain F maps onto a chain of circles F' between C_1' and C_2', and C maps onto a circle C' which touches C_1' and C_2'. Since C_1' and C_2' have a common centre O, we can rotate the chain F' about O until its first circle is superimposed on C'. If we denote the rotated chain by G', then the inversive transformation t^{-1} maps G' back to a chain G between C_1 and C_2. Moreover, the first circle of G is C as required.

Recall that t^{-1} must be an inversive transformation, since t is.



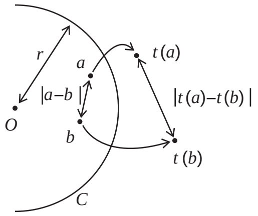
Another famous porism is **Poncelet's Porism**: If C_1 and C_2 are any two plane conics for which (for any given $n > 2$) it is possible to find one n-sided polygon which is simultaneously inscribed in C_1 and circumscribed around C_2, then it is possible to find infinitely many of them.

We omit a proof, as it is beyond the scope of this book.

Next, we prove a classical result known as Ptolemy's Theorem — but using inversion rather than using Ptolemy's Pythagorean geometry methods! A key tool in our proof is the following useful result.

Claudius Ptolemaus (c. 85–165 AD) was a geometer, astronomer and geographer in Alexandria, Egypt.

Lemma 1 Let a and b be points in $\mathbb{C} - \{O\}$. Then, under inversion in a circle C with centre O and radius r the distance between the images of a and b is $\frac{r^2}{|a|\bullet|b|}|a - b|$.



Proof Inversion in C may be represented in the complex plane by the transformation

$$t(z) = \frac{r^2}{\bar{z}}, \quad \text{where } z \in \mathbb{C} - \{O\}.$$

This is a special case of a general formula for inversion in $\mathbb{C}$ that you met in Theorem 3, Subsection 5.2.1.

It follows from this formula that

$$\begin{aligned} t(a) - t(b) &= \frac{r^2}{\bar{a}} - \frac{r^2}{\bar{b}} \\ &= \frac{r^2}{\bar{a}\bullet\bar{b}}(\bar{b} - \bar{a}), \end{aligned}$$

from which we may deduce that

$$|t(a) - t(b)| = \frac{r^2}{|a|\bullet|b|}|b - a|,$$

which is equivalent to the desired result.

The formula for distances in Lemma 1 plays a crucial role in our proof of Ptolemy's Theorem that the sum of the product of the lengths of opposite sides of a cyclic quadrilateral equals the product of the lengths of the diagonals.

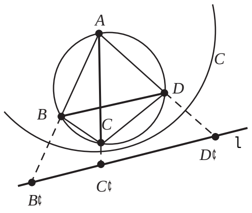
Theorem 9 Ptolemy's Theorem
Let A, B, C, D be the vertices (in order round a circle) of a quadrilateral $ABCD$ inscribed in a circle. Then

$$AD \bullet BC + AB \bullet CD = AC \bullet BD.$$

Proof Let the transformation t be inversion of the figure $ABCD$ in the circle C with centre A and radius 1. This inversion maps A to , the circle C to an extended line (which we will denote by), and the points B, C, D on C to points B , C , D on .

Since B, C, D are in order on C, it follows that B , C , D are in order on . Consequently,

$$B C + C D = B D. \tag{3}$$



Since t is self-inverse, the images of B , C , D under inversion in C are B, C, D. Hence, if we apply the result of Lemma 1 in turn to the distances $B C$, $C D$, $B D$ under the inversion t, it follows from equation (3) that

$$\frac{BC}{AB \bullet AC} + \frac{CD}{AC \bullet AD} = \frac{BD}{AB \bullet AD}.$$

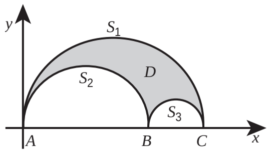
Multiplying both sides of this equation by the product $AB \bullet AC \bullet AD$, we obtain the desired result

$$AD \bullet BC + AB \bullet CD = AC \bullet BD.$$

Our final application of inversion is particularly attractive visually.

Theorem 10 Shoemaker's Knife
Let D be a region in the upper half-plane, whose boundary consists of three semicircles S_1, S_2 and S_3 that meet at three points A, B and C on the x-axis, as shown. Then it is possible to fit a chain of circles into D between S_1 and S_2, with the first circle touching S_i, S_2 and S_3, and with each successive circle touching S_1, S_2 and the previous and following circles in the chain.

The name *Shoemaker s Knife* (or o , *Arbelos*) is due to Archimedes.

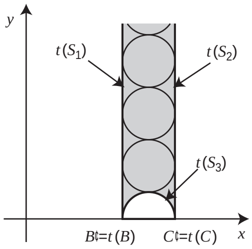


Proof Let t denote inversion in the circle C with centre A and radius 1.

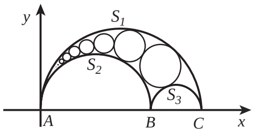
Under t, the positive x-axis maps to itself, and points in the upper half-plane (the set of points above the x-axis) map to points in the upper half-plane.

The circle of which S_3 is a portion is mapped by t to another circle, which crosses the x-axis at right angles, at points B and C say. The image of S_3 is therefore another semicircle in the upper half-plane, with endpoints B and C .

Under t, the origin A maps to , so the semicircles S_1 and S_2 map to portions of (generalized) circles in the upper half-plane that join to B and C , respectively. These portions do not intersect in the (ordinary) plane C, and



they meet the x-axis at right angles. Hence the images of S_1 and S_2 are two vertical half-lines with endpoints B' and C'.



Now, it is obviously possible to fit a chain of circles into the vertical strip bounded by the semicircle $t(S_3)$ and the vertical lines $t(S_1)$ and $t(S_2)$, with the first circle touching $t(S_3)$ and with each successive circle touching $t(S_1)$, $t(S_2)$ and the previous and following circles in the chain.

We can transform this new configuration back into the original configuration by applying the inverse transformation t^{-1}. Since t^{-1} preserves circles and their tangencies, the required result now follows.

Problem 3 Prove that the height above the x-axis of the centre of the n-th circle, C_n say, in the chain of circles constructed in Theorem 10 is n times the diameter of that circle.
Hint: Invert the figure in a circle with centre A that intersects C_n at right angles.

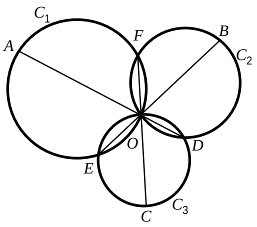
Problem 4 In the figure for Theorem 10, let A, B and C have coordinates (0,0), $(b, 0)$ and $(c, 0)$, respectively. Show that the centres of the circles in the chain constructed in Theorem 10 all lie on an ellipse with foci $F\left(\frac{1}{2}b, 0\right)$ and $F'\left(\frac{1}{2}c, 0\right)$, and major axis $\left[(0, 0), \left(\frac{1}{2}(b + c), 0\right)\right]$.
Hint: Use the Sum of Focal Distances of the Ellipse theorem.

Theorem 5, Subsection 1.1.4

5.6 Exercises

Section 5.1

1. Determine the image under inversion in the unit circle C of each of the following points.
   (a) $(3, -4)$ (b) $(-1, 1)$ (c) $(9, 0)$ (d) $\left(\frac{1}{2}, -\frac{\sqrt{3}}{2}\right)$
2. Determine the image under inversion in the unit circle C of the following circles C (with the origin removed if it belongs to C):
   (a) the circle with centre $(3, -4)$ and radius 5;
   (b) the circle with centre (1, 2) and radius 3.
3. Determine the image under inversion in the unit circle C of the following lines ℓ (with the origin removed if it belongs to ℓ):
   (a) the line $y + 3x = 5$;
   (b) the line $y + 2x = 0$.



4. Three circles C_1, C_2, C_3 pass through the origin O, and meet at three other distinct points D, E and F, as shown. The following sets of points are collinear: A, O and D; B, O and E; C, O and F. OA and OB are diameters of C_1 and C_2, respectively. Prove that OC is a diameter of C_3.
   Hint: Invert the figure in a unit circle with centre O, and then use the fact that the altitudes of a triangle are concurrent.

5. By means of a specific example, show that the centre of the image circle $t(C_2)$ of a circle C_2 under inversion t in another circle C_1 may not be the image of the centre of C_2 under t.
6. Let the origin O, P and Q be distinct points; and let P' and Q', respectively, be the images of P and Q under inversion in the circle with centre O and radius r. Prove that

$$P'Q' = \frac{r^2}{OP \cdot OQ} PQ.$$

(For simplicity, you may assume that O, Q', P' are points inside the circle of inversion and occur in this order along the radius outwards from O. The result holds in all other cases too, by a similar argument.)

7. Let P and Q be distinct points in $\mathbb{C} - \{O\}$ with the origin O, P and Q not being collinear; and let P' and Q', respectively, be their images under inversion in the circle with centre O and radius r. Let ON and ON' be the perpendiculars from O to PQ and $P'Q'$ (extended, if necessary), respectively.
   (a) Prove that

$$P'Q' = \frac{r^2}{OP \cdot OQ} PQ.$$

   (b) Prove that

$$\frac{ON}{PQ} = \frac{ON'}{P'Q'}.$$

8. Let AB be a diameter of a circle C, and let chords AD and BE (extended, if necessary) of C intersect at a point F. Prove that the circle DEF is orthogonal to the circle C.

Section 5.2

1. Let t be the transformation defined by

$$t(z) = \tfrac{1}{2}(1 + \sqrt{3}i)z + 2i \quad (z \in \mathbb{C}).$$

   (a) Show that t represents an isometry.
   (b) Interpret t as the composite of a rotation and a translation.
   (c) Interpret t as a composite of reflections.
2. Determine the image under inversion in the unit circle $\mathcal{C}$ of each of the following points.
   (a) $-3 + 4i$ (b) $5 - 12i$
3. Let C be the circle of radius 2 with centre $1 + i$.
   (a) Write down the inversion in C of the extended complex plane, as a transformation of $\mathbb{C}$.
   (b) Determine the image of i under the inversion in C.

4. Let t be the extended linear function defined by

$$t(z) = \begin{array}{ll} 5iz + (2+6i), & \text{if } z \quad \mathbb{C}, \\ \quad, & \text{if } z = \quad . \end{array}$$

Express t as a composite of inversions of the extended complex plane.

5. Prove that two points z and z in the complex plane correspond to two diametrically-opposite points on the Riemann sphere if and only if $z \bullet \overline{(z\ )} = \quad 1$.

Section 5.3

1. Which of the following formulas define a Möbius transformation? For each formula that does define a Möbius transformation, state the image of under M.
(a) $M(z) = \quad 2\frac{z+1}{z\quad 2}$ (b) $M(z) = \quad 2z + \frac{1}{z\quad 2}$ (c) $M(z) = \frac{2iz\quad 2}{z+i}$

2. Decide which, if any, of the following matrices

$$\mathbf{A}_1 = \begin{matrix} 1 & i \\ i & 1 \end{matrix}, \quad \mathbf{A}_2 = \begin{matrix} 1 & i \\ i & 1 \end{matrix}, \quad \mathbf{A}_3 = \begin{matrix} i & i \\ 1 & i \end{matrix},$$

are associated with each of the following Möbius transformations.
(a) $M_1(z) = \frac{z\quad 1}{iz+1}$ (b) $M_2(z) = \frac{iz\quad 1}{z\quad i}$ (c) $M_3(z) = \frac{z\quad 1}{z+i}$

3. Determine a formula for each of the following Möbius transformations, where M_1 and M_2 are the Möbius transformations defined in Exercise 2.
(a) $M_1 \quad M_1(z)$ (b) $M_1 \quad M_2(z)$ (c) $M_2 \quad M_1^{\quad 1}(z)$

4. State which of the following transformations of $\mathbb{C}$ onto itself are inversive transformations, giving a brief reason in each case.
(a) $t(z) = \frac{4i\quad 2}{3i\quad 2}$ (b) $t(z) = 5$ (c) $t(z) = \frac{iz+2}{z\quad 2i}$

5. Let t be the inversive transformation defined by

$$t(z) = \frac{z+i}{z\quad i}.$$

Determine the image of each of the following generalized circles under t:
(a) the extended line $\quad \{\quad\}$, where $\quad$ is the line with equation $y = x$;
(b) the unit circle $\mathbb{C}$.

Section 5.4

1. For each set of three points below, determine the Möbius transformation that maps the three points to 0, 1, $\quad$, respectively.
(a) i, $\quad i$, $\quad$ (b) $\quad$, 1, i (c) $2i$, $\quad$, 3 (d) 1, 2, 3

2. Using the results of Exercise 1, determine the Möbius transformations that map:
(a) 1, 2, 3 to $2i$, $\quad$, 3; (b) $\quad$, 1, i to i, $\quad i$, $\quad$;
(c) $2i$, $\quad$, 3 to $\quad$, 1, i; (d) i, $\quad i$, $\quad$ to 1, 2, 3.

3. Determine whether each of the following sets of points are collinear:
(a) $\frac{3}{2} + i$, $2i$, $\quad 6 + 6i$ (b) $1 + 2i$, $4 \quad 5i$, $10 \quad 20i$

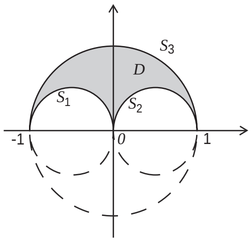
4. Determine whether each of the following sets of points lies on a circle:
   (a) i, 3, $1 + 2i$, $2 + 4i$ (b) $1 \quad 2i$, $4 + i$, $4 + i$, $1 + 6i$

Section 5.5

1. An Apollonian family of circles F includes (6,0) as a point circle and also the circle C with equation $x^2 + y^2 = 4$. Determine the other point circle in the family.
2. The circles C_1 and C_2 in an Apollonian family of circles have the segments [0,8] and $\#1, \frac{7}{2}\$$, respectively, of the x-axis as diameters.
   (a) Determine the point circles of the family.
   (b) Hence determine the equation of the Apollonian circle in the family that passes through the point (1,1).
3. Determine the images under inversion in a unit circle with centre A of the following families F of coaxal circles.
   (a) F is the family of all generalized circles tangential to the y-axis at the origin, and $A = (0, 0)$.
   (b) F is the family of all generalized circles through the points $A = (\quad 1, 0)$ and $B = (1, 0)$.
   (c) F is the Apollonian family of all generalized circles with point circles $A = (\quad 1, 0)$ and $B = (1, 0)$.
4. Let C_1 be the (extended) y-axis in the plane, and C_2 the circle with centre (2, 0) and radius 1. Find a sequence of inversions whose composite inversive transformation maps C_1 and C_2 onto concentric circles.
5. Let C_1 and C_2 be circles that touch at a point P, apart from which C_2 lies inside C_1. Prove that it is possible to fit a chain of circles between C_1 and C_2, with each circle touching C_1 and C_2 and two other circles in the chain, and with the first circle in the chain placed in any convenient position.
6. Prove that, if the Möbius transformation M maps C, the unit circle with centre the origin, to itself, then M is necessarily of the form

$$M(z) = K\frac{z \quad}{\bar{\ }z \quad 1}, \quad \text{where } |K| = 1 \quad \text{and} \quad |\ \ | = 1.$$

7. Let F be an Apollonian family of circles with point circles A and B and radical axis . Prove that, for any given point P on the radical axis, all the tangents from P to circles in F are of equal length.
8. Let D be the region in the upper half-plane whose boundary consists of three semicircles S_1, S_2 and S_3 with diameter the segments [1, 0], [0, 1] and [1, 1], respectively, of the x-axis, as shown.
   (a) Prove that it is possible to fit a chain of circles into D between S_1 and S_2, with the first circle touching S_1, S_2 and S_3, and with each successive circle touching S_1, S_2 and the previous and following circles in the chain.

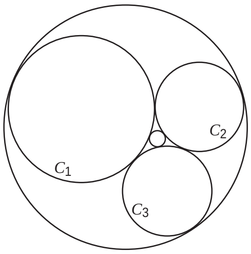


(b) Prove that the n^{th} circle in the chain has its centre at a height $\frac{2n}{4n^2-1}$ above the x-axis, and has radius $\frac{1}{4n^2-1}$.

9. Let C_1, C_2, C_3 be three circles, external to each other, where the pairs C_1 and C_2, C_2 and C_3, and C_3 and C_1 each touch at a point. Prove that there are exactly two circles that touch all of C_1, C_2, C_3.

   These circles are sometimes called *kissing circles* or *Soddy circles*, and were discovered by René Descartes (1643), then rediscovered by Jakob Steiner (1826) and Frederick Soddy (1936). Soddy published his discovery as a poem titled *The Kiss Precise*, in the scientific journal *Nature*; it starts:

   For pairs of lips to kiss maybe
   Involves no trigonometry.
   'Tis not so when four circles kiss
   Each one the other three.
   To bring this off the four must be
   As three in one or one in three.
   If one in three, beyond a doubt
   Each gets three kisses from without.
   If three in one, then is that one
   Thrice kissed internally.



Frederick Soddy (1877–1956) won the 1921 Nobel Prize in chemistry for research into radioactive decay and the theory of isotopes.

Summary of Chapter 5

Section 5.1: Inversion

1. Under **reflection in a line** ℓ in the plane, a point A is mapped to an image point A' that lies an equal distance from ℓ, but on the opposite side of ℓ.
2. Let C be a circle in the plane, with centre O and radius r, and let A be any point other than O. If A' is the point on the line OA that lies on the same side of O as A and satisfies the equation $OA \cdot OA' = r^2$, then we call A' the **inverse** of A with respect to (or *in*) the circle C. The point O is called the **centre of inversion**, and C the **circle of inversion**. The transformation t defined by $t(A) = A'$ $(A \in \mathbb{R}^2 - \{O\})$ is known as **inversion in** C.

   There is no point to which O is mapped by the inversion, and no point that is mapped to O by the inversion.

   Inversion in a circle is a generalization of reflection in a line.

   We often use the term **inversion** to mean EITHER reflection in a line OR inversion in a circle.
3. If A is a point outside a circle C with centre O, AB and AC are the two tangents from A to C, and A' is the point of intersection of OA and BC, then A and A' are inverse points with respect to C.
4. Inversion in a circle C maps points outside C to points inside C, and vice-versa; points on C map to themselves.

Inversion in a circle is a one-one transformation of the plane minus the centre of inversion onto itself.

Inversion is a self-inverse transformation.

5. Inversion is not a Euclidean transformation; for example, it does not preserve lengths.

   Inversion is not an affine transformation; for example, it does not preserve straight lines.

6. Inversion in the unit circle $\mathcal{C}$ is the function $t : (x, y) \mapsto \left(\frac{x}{x^2+y^2}, \frac{y}{x^2+y^2}\right)$, where $(x, y) \in \mathbb{R}^2 - \{O\}$.

   Strategy To determine an equation for the image of a curve under inversion in the unit circle $\mathcal{C}$:

   1. write down an equation that relates the x- and y-coordinates of the points on the curve;
   2. replace x by $x/(x^2 + y^2)$ and y by $y/(x^2 + y^2)$, and simplify the resulting equation.

   If the curve passes through the origin we must first remove the origin from the curve. If we remove a point A from a curve, the curve is said to be **punctured** at A.

7. **Images of lines under inversion** Under inversion in a circle with centre O:

   (a) a line that does not pass through O maps onto a circle punctured at O;
   (b) a line punctured at O maps onto itself.

   Images of circles under inversion Under inversion in a circle with centre O:

   (a) a circle that does not pass through O maps onto a circle;
   (b) a circle punctured at O maps onto a line that does not pass through O.

   Even if inversion maps one circle onto another, it may not map centre to centre.

8. Let c_1 and c_2 be two curves that intersect at the point A, and let the tangents to the curves at A be ℓ_1 and ℓ_2, respectively. Then the **anti-clockwise angle** from c_1 to c_2 at A is the anti-clockwise angle from ℓ_1 to ℓ_2, and the **clockwise angle** from c_1 to c_2 at A is the clockwise angle from ℓ_1 to ℓ_2.

9. **Symmetry Lemma** Let ℓ be a line that does not pass through the point O. Then under inversion in a circle with centre O, ℓ maps to a circle C (punctured at O), and the tangent to C at O is parallel to ℓ.

10. **Angle Theorem** An inversion in any circle preserves the magnitude of angles between curves but reverses their orientation.

Section 5.2: Extending the Plane

1. The transformation $t(z) = z + c$ $(z \in \mathbb{C})$, where $c = a + ib$, is a **translation** through the vector (a, b).

   The transformation $t(z) = \overline{z}$ $(z \in \mathbb{C})$ is a **reflection** in the x-axis.

   The transformation $t(z) = az$ $(z \in \mathbb{C})$, where $|a| = 1$, $a = \cos\theta_0 + i\sin\theta_0$, is a **rotation** through an anti-clockwise angle θ_0 about the origin.

Each isometry t **of the plane** can be represented in the complex plane by one of the functions $t(z) = az + b$ or $t(z) = a\overline{z} + b$, where $a, b \in \mathbb{C}$, $|a| = 1$. Conversely, all such functions represent isometries.

Every isometry can be expressed as a composite of reflections.

2. The transformation $t(z) = kz$ $(z \in \mathbb{C})$, where k is real and positive, is a **scaling** by a **factor** k.
3. An inversion in a circle C of radius r with centre (a, b) may be represented in the complex plane by the transformation $t(z) = \frac{r^2}{\overline{z} - \overline{c}} + c$ $(z \in \mathbb{C} - \{c\})$, where $c = a + ib$.

   In particular, inversion in the unit circle $\mathcal{C}$ may be represented by the transformation $t(z) = \frac{1}{\overline{z}}$ $(z \in \mathbb{C} - \{O\})$.
4. A **linear function** is a function of the form $t(z) = az + b$ $(z \in \mathbb{C})$, where $a, b \in \mathbb{C}$ and $a \neq 0$.

   It may be decomposed into a composite $t_2 \circ t_1$, where t_1 is the scaling $t_1(z) = |a|z$ and t_2 is the isometry $t_2(z) = (a/|a|)z + b$. This can be described geometrically as a scaling by the factor $|a|$, followed by a rotation through the angle $\operatorname{Arg}(a/|a|)$, followed by a translation through the vector $(\operatorname{Re} b, \operatorname{Im} b)$.

   Linear functions preserve angles, and map circles and lines to circles and lines.
5. The **reciprocal function** is the function of the form $t(z) = \frac{1}{z}$ $(z \in \mathbb{C} - \{O\})$.

   It may be decomposed into a composite $t_2 \circ t_1$, where t_1 is the inversion $t_1(z) = 1/\overline{z}$ and t_2 is the conjugation $t_2(z) = \overline{z}$.

   The reciprocal function preserves angles.
6. The **extended (complex) plane** $\hat{\mathbb{C}}$ is the union of the complex plane $\mathbb{C}$ and one extra point, the **point at infinity**, denoted by the symbol ∞.
7. An **extended line** is any line ℓ in the plane together with the point ∞. An extended line can be thought of as a circle of infinite radius.

   A **generalized circle** in the extended plane is a set that is either a circle or an extended line.
8. Let C be a generalized circle in the extended complex plane. Then an **inversion of the extended plane with respect to** C is a function t defined by one of the following rules.
   (a) If C is a circle of radius r with centre O, then

$$t(A) = \begin{cases} \text{the inverse of } A \text{ with respect to } C, & \\ & \text{if } A \in \mathbb{C} - \{O\}, \\ \infty, & \text{if } A = O, \\ O, & \text{if } A = \infty. \end{cases}$$

   (b) If C is an extended line $\ell \cup \{\infty\}$, then

$$t(A) = \begin{cases} \text{the reflection of } A \text{ in } \ell, & \text{if } A \in \mathbb{C}, \\ \infty, & \text{if } A = \infty. \end{cases}$$

Inversions of the extended plane map generalized circles onto generalized circles.

9. The **extended conjugation function**, **extended reciprocal function** and **extended linear functions** may be defined in the natural way as mappings of C to itself.
10. The extended reciprocal function and the extended linear functions can be decomposed into a composite of inversions, and map generalized circles onto generalized circles.
11. **Strategy** To scale C by a factor k:
    1. invert in the circle $\{z : |z| = 1\}$, then
    2. invert in the circle $\{z : |z| = \ \overline{k}\}$.

    Strategy To rotate C through an angle :
    1. invert in the line $\{z : \operatorname{Arg} z = 0\}\ \{\ \}$, then
    2. invert in the line $z : \operatorname{Arg} z = \frac{1}{2}\quad \{\ \}$.

    Strategy To translate C through a vector (a, b):
    1. invert in the line $\{(x, y) : ax + by = 0\}\quad \{\ \}$, then
    2. invert in the line $\{(x, y) : ax + by = \frac{1}{2}(a^2 + b^2)\}\quad \{\ \}$.
12. The **Riemann sphere** S is the sphere in $\mathbb{R}^3$ with centre the origin and radius 1. The points $N(0, 0, 1)$ and $S = (0, 0,\ 1)$ are called the **North Pole** and the **South Pole** of S, respectively.

    Lines through the North Pole intersecting S at points P and the (x, y)-plane at points P give a one one correspondence between points on S and points in the plane. (We associate the North Pole with the point in the extended complex plane.)

    The one-one onto function : S C which maps points on S to the associated points in the extended complex plane is called **stereographic projection**. If (X, Y, Z) S and $z = x + iy$ C, then

$$(X, Y, Z) = \frac{X}{1\quad Z} + i\,\frac{Y}{1\quad Z}$$

    and

$$^{1}(x + iy) = \quad \frac{2x}{x^2 + y^2 + 1}, \frac{2y}{x^2 + y^2 + 1}, \frac{x^2 + y^2\quad 1}{x^2 + y^2 + 1}\quad .$$

13. Under stereographic projection, circles on the Riemann sphere map onto generalized circles in C. In particular, circles on the sphere that pass through N map onto extended lines in C, and circles on the sphere that do not pass through N map onto ordinary circles in C.

    Stereographic projection preserves the magnitude of angles.

Section 5.3: Inversive Geometry

1. A transformation t : C C is an **inversive transformation** if it can be expressed as a composite of inversions.

    Inversive geometry is the study of those properties of figures in C that are preserved by inversive transformations.

The extended reciprocal function and the extended linear functions are inversive transformations.

2. Inversive transformations preserve the magnitude of angles, map generalized circles to generalized circles, and preserve tangency.

   The set of inversive transformations forms a group under the operation of composition of functions, called the **inversive group**.

3. Every Euclidean transformation is also an inversive transformation, and every Euclidean property is also an inversive property.

   The doubling map $t(z) = 2z$ $(z \in \mathbb{C})$ is an affine transformation and an inversive transformation, but is not a Euclidean transformation.

   The transformation of $\mathbb{R}^2$ to itself given by $t(\mathbf{x}) = \begin{pmatrix} 2 & 0 \\ 0 & 1 \end{pmatrix} \mathbf{x}$ represents a horizontal shear; it is an affine transformation, but is not an inversive transformation.

4. A **Möbius transformation** is a function $t : \hat{\mathbb{C}} \to \hat{\mathbb{C}}$ of the form $M(z) = \frac{az+b}{cz+d}$, where $a, b, c, d \in \mathbb{C}$, and $ad - bc \neq 0$.

   If $c = 0$, we adopt the convention that $M(\infty) = \infty$; otherwise we adopt the convention that $M(-d/c) = \infty$ and $M(\infty) = a/c$.

   The extended linear functions and the extended reciprocal function are Möbius transformations.

   Every Möbius transformation is an inversive transformation.

5. Möbius transformations preserve the magnitude and orientation of angles, and map generalized circles onto generalized circles.

6. Let M be a Möbius transformation defined by $M(z) = \frac{az+b}{cz+d}$, where a, b, c, $d \in \mathbb{C}$, and $ad - bc \neq 0$; then $\mathbf{A} = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$ is a matrix **associated** with M.

   A matrix associated with a Möbius transformation is invertible.

   If $\mathbf{A}$ is a matrix associated with a Möbius transformation M, then so is $c\mathbf{A}$ for any non-zero $c \in \mathbb{C}$. Every matrix associated with M has the form $c\mathbf{A}$ for some $c \in \mathbb{C} - \{O\}$.

7. Let M_1 and M_2 be Möbius transformations with associated matrices $\mathbf{A}_1$ and $\mathbf{A}_2$, respectively. Then $M_1 \circ M_2$ is a Möbius transformation with associated matrix $\mathbf{A}_1\mathbf{A}_2$.

   Strategy To compose two Möbius transformations M_1 and M_2:

   1. write down matrices $\mathbf{A}_1$ and $\mathbf{A}_2$ associated with M_1 and M_2;
   2. calculate $\mathbf{A}_1\mathbf{A}_2$;
   3. write down the Möbius transformation $M_1 \circ M_2$ with which $\mathbf{A}_1\mathbf{A}_2$ is associated.

8. The inverse of the Möbius transformation $M(z) = \frac{az+b}{cz+d}$ is also a Möbius transformation, and it may be written in the form $M^{-1}(z) = \frac{dz-b}{-cz+a}$.

9. The set of all Möbius transformations forms a group under composition of functions.

10. Every inversion t has the form $t(z) = M(\bar{z})$, where M is a Möbius transformation.

Every inversive transformation t can be represented in C by one of the formulas $t(z) = \frac{az+b}{cz+d}$ or $t(z) = \frac{a\bar{z}+b}{c\bar{z}+d}$, where $a, b, c, d \quad$ C, and $ad \quad bc = 0$.

The composite of an even number of inversions is a Möbius transformation and is called a **direct** inversive transformation (since it preserves the orientation of angles); the composite of an odd number of inversions is called an **indirect** inversive transformation (since it reverses the orientation of angles).

11. **Strategy** To determine the image of a generalized circle C under an inversive transformation t:
    1. write down three points z_1, z_2, z_3 on C;
    2. determine the images $t(z_1), t(z_2), t(z_3)$;
    3. the image $t(C)$ is the (unique) generalized circle through $t(z_1)$, $t(z_2)$, $t(z_3)$.

Section 5.4: Fundamental Theorem of Inversive Geometry

1. **Fundamental Theorem of Inversive Geometry**
   Let z_1, z_2, z_3 and w_1, w_2, w_3 be two sets of three points in the extended complex plane C. Then there is a unique Möbius transformation M which maps z_1 to w_1, z_2 to w_2, and z_3 to w_3.
2. **Strategy** To determine the Möbius transformation M which maps three given points z_1, z_2, z_3 onto the points 0, 1 and , respectively:
   1. choose the appropriate form of mapping from the following formulas for M:

mapping	form of M
$z_1, z_2, z_3 \qquad 0, 1,$	$K\frac{z \quad z_1}{z \quad z_3}$
$, z_2, z_3 \qquad 0, 1,$	$\frac{K}{z \quad z_3}$
$z_1, \quad , z_3 \qquad 0, 1,$	$\frac{z \quad z_1}{z \quad z_3}$
$z_1, z_2, \qquad 0, 1,$	$K(z \quad z_1)$

   2. find the complex number K for which $M(z_2) = 1$.
3. **Strategy** To determine the Möbius transformation M which maps the points z_1, z_2, z_3 to the points w_1, w_2, w_3, respectively:
   1. find the Möbius transformation M_1 which maps the points z_1, z_2, z_3 to the points 0, 1, , respectively;
   2. find the Möbius transformation M_2 which maps the points w_1, w_2, w_3 to the points 0, 1, , respectively;
   3. calculate $M = M_2^{\ 1} \quad M_1$.
4. **Strategy** To determine whether z_1, z_2, z_3 and z_4 lie on a circle:
   1. find the Möbius transformation M which maps z_1, z_2, z_3 to 0, 1, , respectively;
   2. the points z_1, z_2, z_3, z_4 lie on a generalized circle if and only if $M(z_4)$ is real;

   3. the generalized circle in Step 2 is a circle provided that $M(\infty)$ is not real.

   If $M(z_4)$ and $M(\infty)$ are both real, then z_1, z_2, z_3, z_4 lie on a line.

5. Let C_1 and C_2 be generalized circles in the extended complex plane. Then there is a Möbius transformation that maps C_1 onto C_2.

   All generalized circles are inversive-congruent.

Section 5.5: Coaxal Families of Circles

1. **Apollonian Circles Theorem** Let A and B be two distinct points in the plane, and let k be a positive real number other than 1. Then the locus of points P that satisfy $PA : PB = k : 1$ is a circle whose centre lies on the line through A and B.

   The centre of the circle is not at either A or B. If $A = (-a, 0)$ and $B = (a, 0)$, then the circle has centre c and radius r where $c = \left(-a\frac{1+k^2}{1-k^2}, 0\right)$ and $r = \frac{2ak}{|1-k^2|}$.

   If $k = 1$, then P lies on the perpendicular bisector of AB.

   Every positive value of k gives rise to a generalized circle, known as a **circle of Apollonius**; the family of all such circles is known as the **Apollonian family of circles** defined by the points A and B.

   If $0 < k < 1$, the Apollonian circle surrounds A; if $k > 1$, the Apollonian circle surrounds B. The points A and B are called **point circles**, corresponding to the cases $k = 0$ and $k = \infty$, respectively. Every point in the plane lies on precisely one circle (or generalized circle) in each Apollonian family.
2. Let A and B be distinct points in the plane, and let t be the inversion in the circle with centre A and radius 1. Then the Apollonian family of circles defined by the point circles A and B is mapped by t to the family of all concentric circles with centre $t(B)$; and the family of all concentric circles with centre $t(B)$ is mapped by t to the Apollonian family of circles defined by the point circles A and B.
3. A **coaxal family of circles** in the plane is a family of (generalized) circles of one of the following types:
   1. an Apollonian family, with particular point circles;
   2. a family that intersect at one particular point;
   3. a family that intersect at two particular points.

   The extended line in each family is called the **radical axis** of the family.

   Coaxal Circles Theorem Let A and B be distinct points in the plane. Let $\mathcal{F}$ be the Apollonian family defined by the point circles A and B, and let $\mathcal{G}$ be the family of all generalized circles through A and B. Then every member of $\mathcal{F}$ is orthogonal to every member of $\mathcal{G}$.
4. Two points A and B in the extended complex plane are inverse points with respect to a generalized circle C if and only if every generalized circle through A and B meets C at right angles.

If C is an Apollonian circle defined by the point circles A and B, then A and B are inverse points with respect to C.

Let A and B be inverse points with respect to a generalized circle C, and let t be an inversive transformation. Then $t(A)$ and $t(B)$ are inverse points with respect to the generalized circle $t(C)$.

Let $\mathcal{F}$ be the family of all generalized circles that have A and B as inverse points. Then $\mathcal{F}$ is either a concentric family of circles with centre A or B, or an Apollonian family of circles with point circles A and B.

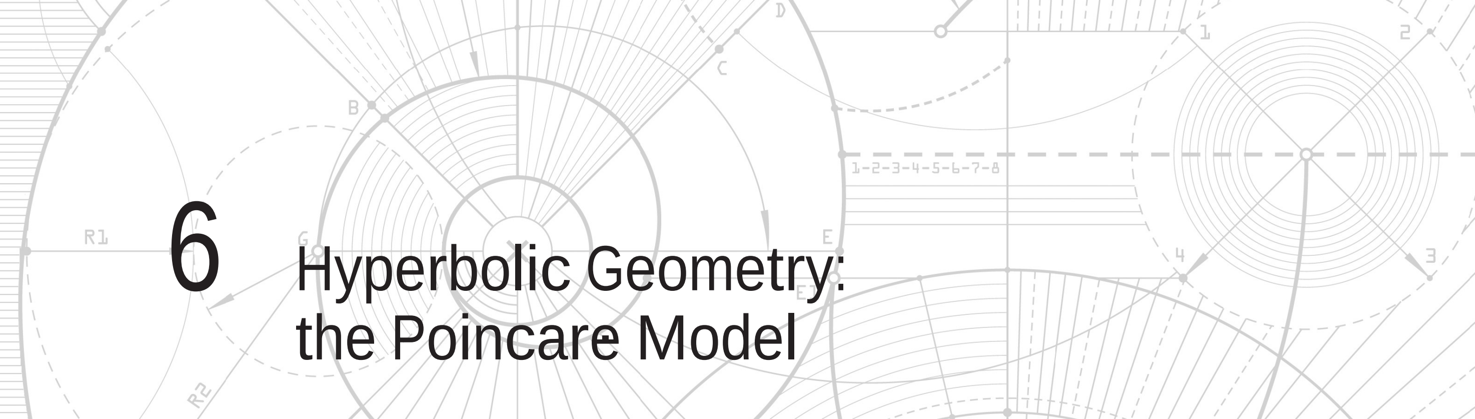
Let C and C_1 be circles that meet at right angles at two points R and S. Then the centre of C_1 is the point T of intersection of the tangents to C at R and S; and C_1 maps to itself under inversion in C.

5. **Concentricity Theorem** Let C_1 and C_2 be any two non-intersecting circles in the plane. Then there is an inversive transformation that maps C_1 and C_2 onto a pair of concentric circles.
6. **Two Apollonian Circles Theorem** Let C_1 and C_2 be two non-concentric circles that do not intersect. Then there is a unique Apollonian family of circles that contains C_1 and C_2.
7. A **porism** is a mathematical construction problem that has a surprising answer: either the construction cannot be carried out or it has infinitely many solutions.

   Steiner's Porism Let C_1 and C_2 be non-intersecting circles, with C_1 inside C_2. Then EITHER it is impossible to fit a chain of circles between C_1 and C_2, with each circle touching C_1 and C_2 and two other circles in the chain OR it is possible to construct such a chain, and the first circle in the chain can be placed in any convenient position.

   Poncelet's Porism If C_1 and C_2 are any two plane conics for which (for any given $n > 2$) it is possible to find one n-sided polygon which is simultaneously inscribed in C_1 and circumscribed around C_2, then it is possible to find infinitely many of them.
7. Let a and b be points in $\mathbb{C} - \{O\}$. Then, under inversion in a circle C with centre O and radius r the distance between the images of a and b is $\frac{r^2}{|a|\cdot|b|}|a - b|$.

   Ptolemy's Theorem Let A,B,C,D be the vertices (in order) of a quadrilateral inscribed in a circle. Then $AD \cdot BC + AB \cdot CD = AC \cdot BD$.
8. **Shoemaker's Knife/Arbelos** Let D be a region in the upper half-plane, whose boundary consists of three semicircles S_1, S_2 and S_3 that meet at three points A, B and C on the x-axis. Then it is possible to fit a chain of circles into D between S_1 and S_2, with the first circle touching S_1, S_2 and S_3, and with each successive circle touching S_1, S_2 and the previous and following circles in the chain.



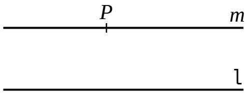
6

Hyperbolic Geometry: the Poincare Model

The book, Euclid's *Elements*, which underlay most geometrical teaching in Western Europe for over 2000 years, gave definitions of the basic terms in geometry and rules (called postulates) for their use. Many of Euclid's assumptions seem entirely uncontroversial, such as the assertions that through any two distinct points in a plane or in space there passes a unique line, and that a line can be extended indefinitely in both directions. On these foundations Euclid gave rigorous proofs of theorems in elementary geometry, which could be accepted as true because of the way they had been established.

Among the postulates for Euclidean geometry is one about parallel lines which is equivalent to the following statement.

The (Euclidean) Parallel Postulate Given any line ℓ and a point P not on ℓ, there is a unique line m in the same plane as P and ℓ which passes through P and does not meet ℓ.

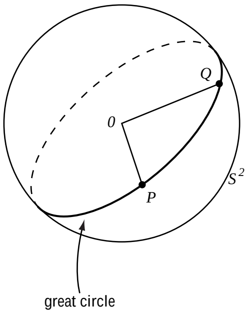


Note that the parallel postulate makes two assertions: first that the parallel line exists, and second that it is unique.

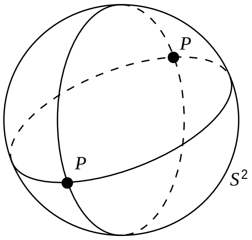
Historically it was felt that the Parallel Postulate as it stands is not obvious. It implies that every line through P other than m eventually meets ℓ, but plainly this meeting place can be a long way away. How much confidence would you place in an assumption about lines meeting somewhere in the Virgo star cluster, some 100 million light years away?

Many Greek, Arab and later Western geometers had felt that the answer was 'not much', and had tried to delete the Euclidean Parallel Postulate from the list and instead derive it as a theorem. They all failed, and in the end the reason was laid bare: the Parallel Postulate cannot be made into a theorem in this way because there are internally consistent models of geometries which obey all the Euclidean postulates except the Parallel Postulate.

But how do we obtain geometries other than Euclidean geometry with its Parallel Postulate? One way to do this might be to insist that any two lines intersect. The geometry to which this gives rise is called *Elliptic Geometry*. One model of elliptic geometry is *Spherical Geometry* (for example, on the surface of the Earth), and we shall investigate this model in Chapter 7.



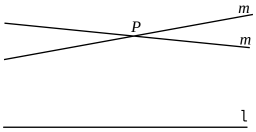
A line PQ on the surface of a sphere (which we call S^2), such as on the Earth s surface, can be defined to be the *great circle* (that is, the intersection of the plane through the centre O of the sphere with the surface of the sphere) through the two points P and Q. Any two distinct great circles meet in two (diametrically opposite) points, such as P and P shown in the margin, so any two lines in spherical geometry meet in two points.



Generalizing this fact, in *Elliptic Geometry* we keep all the other postulates that collectively describe Euclidean geometry, remove the Parallel Postulate, and replace it with the following analogue.

The (Elliptic) Parallel Postulate Given any line and a point P not on , all lines through P meet . (That is, there are no lines through P that are parallel to .)

Another way to obtain a non-Euclidean geometry is to insist that the line through P that does not meet is not unique. We could again keep all the other postulates that collectively describe Euclidean geometry, remove the Parallel Postulate, and replace it with the following.



The (Hyperbolic) Parallel Postulate Given any line and a point P not on , there are at least two lines m through P that do not meet . (That is, there are at least two lines through P that are parallel to .)

The geometry whose postulates are those of Euclidean geometry but with this variant of the Euclidean parallel postulate is called *Hyperbolic Geometry*. The term *non-Euclidean Geometry* is often used to describe elliptic and hyperbolic geometries together.

In fact there are still other geometries (and other models of both hyperbolic and elliptic geometries), that lie beyond the scope of this book.

Non-Euclidean geometry was discovered independently in the late 1820s by the distinguished Russian mathematician Nicolai Ivanovich Lobachevskii (1792 1856), working at the University of Kazan, and the Hungarian JÆnos Bolyai (1802 1860), an Army officer whose father, Farkas (or Wolfgang) (1775 1856), was also a mathematician. Many of the same ideas were also known to Carl Friedrich Gauss (1777 1855), but he did not publish them. However, non-Euclidean geometry was not accepted until after these three were dead, when the German Bernhard Riemann (1826 1866) and the Italian Eugenio Beltrami (1835 1900) published their ideas about geometry in the late 1860s. Riemann gave the appropriate general setting, Beltrami a specific account of non-Euclidean geometry. Only then did the new geometry become rapidly accepted. Amongst other things, it spurred Felix Klein (1849 1925) to propose his view of geometry.

Non-Euclidean geometry was one of the most momentous mathematical discoveries of the l9th century. It had several revolutionary implications, because it provided a physically plausible description of space that differed markedly from Euclid s. It became possible to imagine that the universe is not Euclidean, and in the 19th century some mathematicians and astronomers, such as Gauss and his friend Bessel), entertained the idea quite seriously.

Friedrich Wilhelm Bessel (1784 1846) was a German mathematician and astronomer, after whom Bessel functions are named.

The theorems in non-Euclidean geometries often differ markedly from their Euclidean equivalents. For example, in Euclidean geometry the angles of any triangle sum to ; in elliptic geometry the angle sum of any triangle turns out to be strictly greater than , whereas in hyperbolic geometry the angle sum of any triangle turns out to be strictly less than .

In this chapter we shall concentrate on a model of hyperbolic geometry due to the French mathematician Henri Poincaré. In this model (which we will generally call hyperbolic geometry for simplicity), the space of points is the interior of the unit disc $\mathbb{D} = \{z : |z| < 1\}$. All figures in this geometry will be drawn as they appear in this disc. In Section 6.1 we define *hyperbolic lines* and *hyperbolic angles*. We then introduce *hyperbolic reflections* in these lines, and obtain the *group of hyperbolic transformations*: a hyperbolic transformation is a composite of hyperbolic reflections. In Section 6.2 we see that every hyperbolic transformation can be described as either a Möbius transformation (of a certain form) or a Möbius transformation composed with complex conjugation.

You met Möbius transformations in Subsection 5.3.3.

The properties of hyperbolic geometry include angle and length, and so we can define *hyperbolic circles*, which we do in Section 6.3. We also obtain a formula relating Euclidean lengths and *hyperbolic lengths* (at least in special cases), and in Section 6.4 we give useful formulas for the study of hyperbolic triangles. In Section 6.5 we look at *area* in hyperbolic geometry, and at hyperbolic tilings, or *tessellations*, such as the one displayed on the cover of this book. Finally, in Section 6.6 we briefly discuss the half-plane model of hyperbolic geometry.

6.1 Hyperbolic Geometry: the Disc Model

6.1.1 What is Hyperbolic Geometry?

The **points** or ***d*-points** (where d stands for disc) in (Poincaré s version of) hyperbolic geometry consist of the points in the unit disc

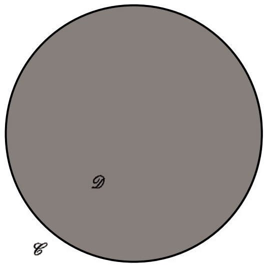
$$\mathbb{D} = \{z : |z| < 1\} = \left\{(x, y) : x^2 + y^2 < 1\right\}.$$

Note that we shall use the alternative notations z and (x, y) freely to describe points in $\mathbb{D}$, according to convenience.

In sketches we usually illustrate $\mathbb{D}$ by drawing in its boundary

$$\mathbb{C} = \{z : |z| = 1\} = \left\{(x, y) : x^2 + y^2 = 1\right\},$$

but you should note that points on $\mathbb{C}$ are *not* points which belong to the geometry.



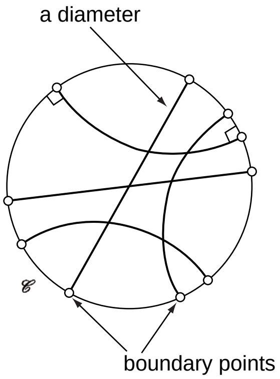
A crucial feature of this geometry is the concept of a *d-line*, or a *line in hyperbolic geometry.*

Definition A ***d*-line** is that part of a (Euclidean) generalized circle which meets C at right angles and which lies in D.

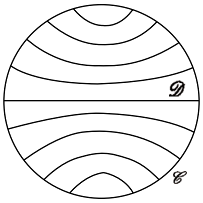
A generalized circle is either a circle or a (Euclidean) line; see Subsection 5.2.3.

Every d-line is part of a generalized (Euclidean) circle which meets the boundary circle in two points. We call these two points the **boundary points** of the d-line. Notice that the boundary points of a d-line are not d-points for they are not points in D.

The sketch below illustrates various d-lines. Some of these d-lines are arcs of (Euclidean) circles; some are (Euclidean) line segments, in fact, diameters of D.

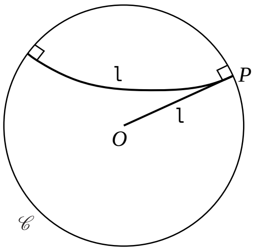


You may find the following figure a helpful reminder for the shapes of d-lines:

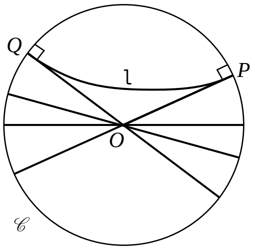


In fact, any d-line that is part of a Euclidean line must be a diameter of D, since otherwise it cannot meet C at right angles.

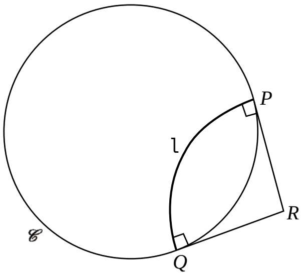
Conversely, any d-line that is an arc of a Euclidean circle cannot pass through the origin. For if meets C at a point P, then the tangent to at P is a radius of C and so passes through the origin O, which is the centre of C. But then is a line touching the Euclidean circle at P, and because circles lie entirely on one side of their tangents, cannot meet again. Thus cannot pass through O.



Indeed, if is a d-line that is an arc of a Euclidean circle, then there is a diameter of D that does not meet it. For, if meets C at the points P and Q, then the tangents to at P and Q are radii of C and so pass through the origin. They divide the disc D into four regions, one of which contains . Clearly, a diameter can be drawn that lies entirely in two of the other regions in fact, you can see that there are infinitely many such diameters. Each of these divides D into two regions, one which contains and one which does not.



Notice also that if a d-line is part of a Euclidean circle meeting C at points P and Q, then its centre is the point R where the tangents to C at P and Q meet. So the point R lies outside the circle C.



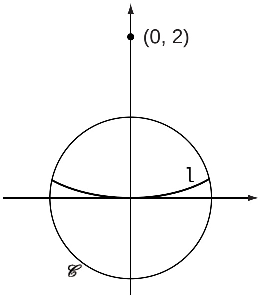
Sometimes it is clear from a (reasonably accurate) sketch whether or not part of a generalized circle is a d-line. For example, consider

$$\ell = \left\{(x, y) : x^2 + y^2 - 4y = 0\right\} \cap \mathbb{D}.$$

Since

$$x^2 + y^2 - 4y = 0 \Leftrightarrow x^2 + (y - 2)^2 = 4,$$

we can sketch ℓ, and deduce that it is not a d-line since it clearly does not meet $\mathcal{C}$ right angles. (The tangents to ℓ at its boundary points on $\mathcal{C}$ do not pass through the origin.)



Problem 1 Sketch the following parts of generalized circles, and determine which of them are d-lines.

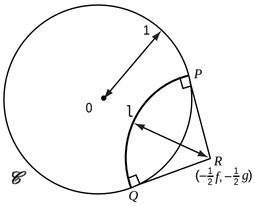
$$\ell_1 = \{(x, y) : y = 3x\} \cap \mathbb{D}$$
$$\ell_2 = \{(x, y) : 3x + y = 1\} \cap \mathbb{D}$$
$$\ell_3 = \left\{(x, y) : x^2 + y^2 + 2x + 2y + 1 = 0\right\} \cap \mathbb{D}$$

Now, it is rather easy to be mislead by a sketch into believing that something is true in general whereas it is not! So, we now give an analytic criterion for identifying d-lines.

Lemma 1 The equation of a d-line ℓ is of one of the following forms:

$ax + by = 0$, where a and b are not both zero;

$x^2 + y^2 + fx + gy + 1 = 0$, where $f^2 + g^2 > 4$.



Proof If a d-line ℓ is (part of) a Euclidean line through the origin, then certainly its equation is of the form $ax + by = 0$, where a and b are not both zero.

The other possibility is that the d-line ℓ is (part of) a Euclidean circle C that intersects the boundary $\mathcal{C}$ of $\mathbb{D}$ at right angles. So, let C have equation

$$x^2 + y^2 + fx + gy + h = 0, \text{ for some real numbers } f, g \text{ and } h.$$

First, it follows from the Orthogonality Test that any circle with this equation intersects the unit circle $\mathcal{C}$ with equation

$$x^2 + y^2 - 1 = 0$$

Subsection 1.1.2, Theorem 3

if and only if

$$f \cdot 0 + g \cdot 0 = 2 \cdot (h + (-1));$$

that is, if and only if $h = 1$. So the equation of C must be of the form

$$x^2 + y^2 + fx + gy + 1 = 0, \text{ for some } f \text{ and } g.$$

Next, the centre $\left(-\frac{1}{2}f, -\frac{1}{2}g\right)$ of C must be outside $\mathbb{C}$, so that $\left(-\frac{1}{2}f\right)^2 + \left(-\frac{1}{2}g\right)^2 > 1$, which we can equivalently write in the form $f^2 + g^2 > 4$.

Finally, we need the circle C to meet $\mathbb{D}$. This happens if and only if

$$1 + \text{radius of } C > \text{distance of the centre of } C \text{ from } O;$$

since $h = 1$ we can write this requirement in the form

$$1 + \sqrt{\frac{1}{4}f^2 + \frac{1}{4}g^2 - 1} > \sqrt{\frac{1}{4}f^2 + \frac{1}{4}g^2}. \qquad (1)$$

Since we already know that $\sqrt{\frac{1}{4}f^2 + \frac{1}{4}g^2} > 1$, the inequality (1) follows at once if we can prove that

$$1 + \sqrt{t - 1} > \sqrt{t}, \quad \text{whenever } t > 1. \qquad (2)$$

Here we are writing t in place of $\frac{1}{4}f^2 + \frac{1}{4}g^2$.

So, let $F(t) = 1 + \sqrt{t-1} - \sqrt{t}$. Then

$$\begin{aligned} F(1) &= 1 + \sqrt{0} - \sqrt{1} \\ &= 0, \end{aligned}$$

and

$$\begin{aligned} F'(t) &= \frac{1}{2\sqrt{t-1}} - \frac{1}{2\sqrt{t}} \\ &= \frac{\sqrt{t} - \sqrt{t-1}}{2\sqrt{t-1}\sqrt{t}} > 0. \end{aligned}$$

It follows at once that $F(t) > F(1) = 0$ for $t > 1$, and so that the inequality (2) holds, as required.

Thus, for example, let C be the circle in $\mathbb{R}^2$ with equation

$$x^2 + y^2 + 3x - 2y + 1 = 0,$$

and let be the part of C that lies in $\mathbb{D}$. Then is a d-line since its equation is of the form required by Lemma 1, with $f = 3$ and $g = -2$, and $f^2 + g^2 = 3^2 + (-2)^2 = 13 > 4$.

In fact, C is the circle with centre $\left(-\frac{3}{2}, 1\right)$ and radius $\sqrt{\left(-\frac{3}{2}\right)^2 + (-1)^2 - 1} = \frac{3}{2}$.

Note the following useful result that we obtain from putting $a = -\frac{1}{2}f$, $b = -\frac{1}{2}g$ into Lemma 1.

Corollary 1 Let $= a + ib$ be a point outside the unit circle $\mathbb{C}$. Then the d-line that is part of a Euclidean circle with centre has equation

$$x^2 + y^2 - 2ax - 2by + 1 = 0.$$

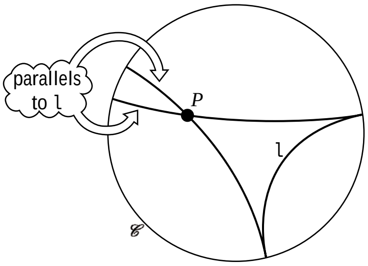
We can now turn to the question of parallelism, the notion that gave rise to the discovery of non-Euclidean geometries in the first place.

Definition Two d-lines that do not meet in $\mathbb{D}$ are:
parallel if the generalized Euclidean circles of which they are parts meet at a point on $\mathbb{C}$;
ultra-parallel if the generalized Euclidean circles of which they are parts do not meet on $\mathbb{C}$.

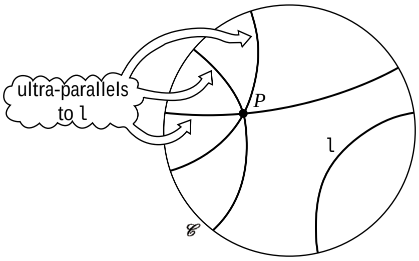
Recall that the boundary $\mathbb{C}$ is *not* part of the unit disc $\mathbb{D}$.

Remarks

1. It follows that given any d-line ℓ and any point P in $\mathbb{D}$ which is not on ℓ, there exist exactly two d-lines through P which are parallel to ℓ, as the next figure shows. A rigorous proof that such d-lines exist will be found below (Problem 5).



2. Similarly, corresponding to any given d-line ℓ and any point P in $\mathbb{D}$ which is not on ℓ, there exist infinitely many d-lines through P which are ultra-parallel to ℓ.



Problem 2 The following sets represent d-lines:

$$\ell_1 = \{(x,y) : y = x\} \cap \mathbb{D};$$
$$\ell_2 = \left\{(x,y) : x^2 + y^2 - 4x + 1 = 0\right\} \cap \mathbb{D};$$
$$\ell_3 = \left\{(x,y) : x^2 + y^2 - 2\sqrt{2}x + 1 = 0\right\} \cap \mathbb{D};$$
$$\ell_4 = \left\{(x,y) : x^2 + y^2 + 2x + 2y + 1 = 0\right\} \cap \mathbb{D}.$$

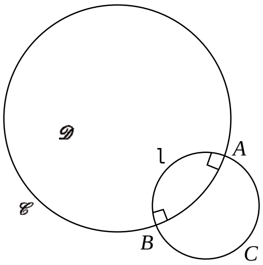
Sketch them, and decide from your figure which of the d-lines intersect each other, which are parallel, and which are ultra-parallel.

Problem 3 Sketch three d-lines ℓ_1, ℓ_2 and ℓ_3 with the property that ℓ_1 is parallel to ℓ_2, and ℓ_2 is parallel to ℓ_3, but ℓ_1 is not parallel to ℓ_3.

It follows that the relation is parallel to is not an equivalence relation in hyperbolic geometry.

In Euclidean geometry and in inversive geometry, reflection and inversion played important roles; this is also the case in hyperbolic geometry. Obviously, reflection of the unit disc $\mathcal{D}$ in a diameter maps $\mathcal{D}$ onto itself; in fact, so does inversion of $\mathcal{D}$ in a d-line that does not pass through the origin.

Theorem 1 Let ℓ be a d-line that is part of a Euclidean circle C. Then inversion in C maps $\mathcal{C}$ onto $\mathcal{C}$, and $\mathcal{D}$ onto $\mathcal{D}$.



Proof Let C meet $\mathcal{C}$ at the points A and B.

Under inversion in C, A and B map to themselves. Since inversion preserves angles, the circle $\mathcal{C}$ maps onto some circle that meets C at right angles at the points A and B. There is only one such circle, $\mathcal{C}$ itself; it follows that inversion in C maps $\mathcal{C}$ onto itself.

Subsection 5.1.3, Theorem 5

Hence the inside $\mathcal{D}$ of $\mathcal{C}$ must map either to the inside or to the outside of the image of $\mathcal{C}$, namely $\mathcal{C}$ itself. But the points of ℓ map to themselves under this inversion, so the image of $\mathcal{D}$ must be $\mathcal{D}$ itself.

Inversion in C maps the shorter arc AB of $\mathcal{C}$ onto the longer arc AB of $\mathcal{C}$, and vice versa.

Inversion in C maps the region bounded by ℓ and the shorter arc AB of $\mathcal{C}$ onto the region bounded by ℓ and the longer arc AB of $\mathcal{C}$, and vice versa.

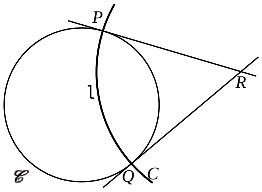
We now know that inversion in a d-line maps the disc $\mathcal{D}$ onto itself. We also know that the composition of an inversion with itself is the identity map. Because the analogous properties are true of Euclidean reflections, we make the following definition.

Definition A **hyperbolic reflection** in a d-line ℓ is the restriction to $\mathcal{D}$ of the inversion in the generalized circle of which ℓ is part.

Recall that we use the term inversion to mean *either* reflection in a line *or* inversion in a circle (see Subsection 5.1.1, Convention).

Remarks

1. If the d-line ℓ is part of a Euclidean circle C meeting the boundary circle $\mathcal{C}$ at points P and Q, then the point R where the tangents to $\mathcal{C}$ at P and Q meet is the centre of the inversion.
2. Notice that Theorem 1 may be reformulated as follows: hyperbolic reflection in any d-line maps the unit disc $\mathcal{D}$ onto itself.



Hyperbolic reflections are the building blocks of transformations in hyperbolic geometry. Composites of a finite number of hyperbolic reflections are called **hyperbolic transformations**. The set of all such transformations under the operation of composition of functions forms a group, called the **hyperbolic group**, $G_{\mathcal{D}}$.

A proof of the fact that these form a group will be found as an Exercise in Section 6.7; it consists simply of checking the axioms for a group.

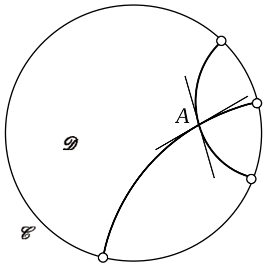
Definition **Hyperbolic geometry** consists of the unit disc, $\mathcal{D}$, together with the group $G_{\mathcal{D}}$ of hyperbolic transformations.

Remarks

1. Notice, in particular, that the identity mapping of $\mathbb{D}$ to itself belongs to $G_{\mathbb{D}}$, since it may be expressed as the finite composition $r \circ r^{-1}$ for any hyperbolic reflection r. Also, if $t_1 \circ t_2 \circ \ldots \circ t_n$ is any hyperbolic transformation, then its inverse is another hyperbolic transformation $t_n^{-1} \circ \ldots \circ t_2^{-1} \circ t_1^{-1}$.
2. Let the generalized circle C of which a d-line ℓ is part meet the boundary circle $\mathbb{C}$ in points P and Q, and let r be the hyperbolic reflection in ℓ. Then although r has domain the unit disc $\mathbb{D}$, and $P, Q \notin \mathbb{D}$, we sometimes find it convenient to call P and Q the boundary points of ℓ and to write the images of P and Q under inversion in C (of which r is a restriction) as $r(P)$ and $r(Q)$. The same convention is extended to the case where r is a hyperbolic transformation.

Next, we define the idea of angle in hyperbolic geometry.

Definition The **(hyperbolic) angle between two curves** (for example, two d-lines) through a given point A in $\mathbb{D}$ is the Euclidean angle between their (Euclidean) tangents at A.



Now, Euclidean reflections and inversions both preserve the magnitudes of angles. It follows that hyperbolic transformations also preserve magnitudes of angles. Also, Euclidean reflections and inversions map generalized circles onto generalized circles. Combining this with the angle-preservation property, we deduce that hyperbolic reflections and inversions map d-lines onto d-lines and so compositions of a finite number of such transformations also have this property. We summarize these facts in the following result.

Theorem 2 Hyperbolic transformations map d-lines onto d-lines, and preserve the magnitudes of angles.

In the remainder of Chapter 6 we study the properties of various figures under hyperbolic transformations, and obtain surprising (and sometimes beautiful) results!

6.1.2 Existence of *d*-lines

Through a typical point A of $\mathbb{D}$ there is at least one d-line: namely, the diameter through the origin O and A. But through the origin there are infinitely many d-lines: the diameters of $\mathbb{D}$. Is there more than one d-line through an arbitrary point A of $\mathbb{D}$?

The first step towards answering this question is the following useful result, which shows that there is a hyperbolic transformation which maps A to O.

Lemma 2 Origin Lemma
Let A be a point of $\mathbb{D}$ other than the origin O. Then there exists a d-line ℓ such that hyperbolic reflection in ℓ maps A to O.

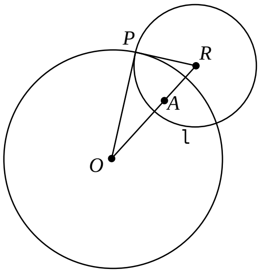
Proof We seek a d-line which is part of a Euclidean circle with centre R, say, such that inversion in this circle maps A to O. Suppose that this circle meets $\mathcal{C}$ at the point P.

The condition that this inversion maps A to O is

$$RO \bullet RA = RP^2, \tag{3}$$

since RP is a radius of the circle we seek.

The condition that part of this circle is a d-line is that triangle RPO is right-angled at P. By Pythagoras Theorem, this implies that



$$RP^2 + PO^2 = RO^2,$$

which, since $OP = 1$, is equivalent to

$$RP^2 = RO^2 - 1. \tag{4}$$

Eliminating the radius RP^2 from equations (3) and (4), we deduce that

$$RO \bullet RA = RO^2 - 1.$$

This is equivalent to

$$RO^2 - RO \bullet RA = 1$$

or

$$RO \bullet (RO - RA) = 1.$$

But $RO - RA = AO$, so we deduce that

$$RO \bullet AO = 1$$

which is equivalent to

$$OA \bullet OR = 1.$$

This tells us that the circle we seek has for its centre the point R which is found by inverting the given point A in the boundary circle $\mathcal{C}$ an unexpectedly memorable result!

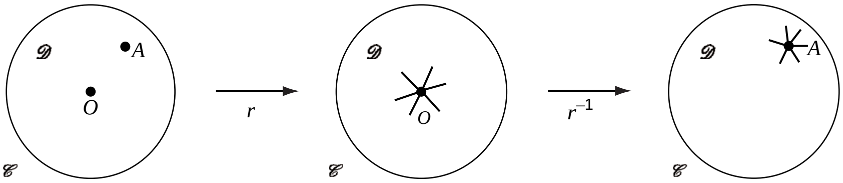
The great value of the Origin Lemma is that it enables us to study any problem in hyperbolic geometry by mapping a suitably chosen point to the origin, thereby yielding a (frequently) simpler picture than before yet without losing any generality. We shall use this method often in this chapter.

We can, for example, use this approach to answer the question of how many d-lines pass through a given point of $\mathcal{D}$.

Theorem 3 Let A be a point of $\mathcal{D}$. Then there exist infinitely many d-lines through A.

Proof Let A be the origin. As we said above, each of the infinitely many diameters of $\mathcal{D}$ passes through the origin, and each of these diameters is a d-line.

If A is not the origin, then by the Origin Lemma, there is a hyperbolic transformation, r say, that maps A to the origin O, through which pass infinitely many d-lines all the diameters of $\mathcal{D}$.



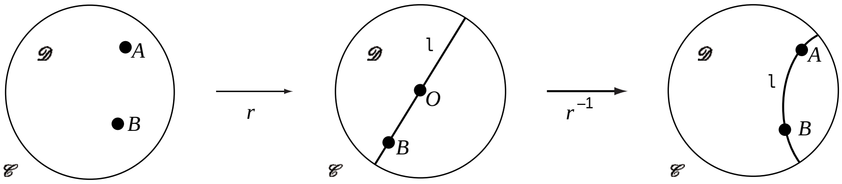
Since r ^{1} is also a hyperbolic transformation, it follows that the images of these diameters are also d-lines and they pass through A.

For, hyperbolic transformations map d-lines to d-lines, by Theorem 2.

An important result in Euclidean geometry is that there is exactly one line through any two given points. There is an analogous result in hyperbolic geometry.

Theorem 4 Let A and B be any two distinct points of D. Then there exists a unique d-line through A and B.

Proof (Existence) By the Origin Lemma, there is a hyperbolic transformation r that maps A to the origin O; let the image of B under r be the point B of D.



Then there is a unique d-line (a diameter of D) that passes through O and B . Since r ^{1} is also a hyperbolic transformation, it follows that $= r$ $^{1}($ $)$ is also a d-line (by Theorem 2) and it passes through A and B.

(Uniqueness) Suppose that $_1$ is another d-line through A and B. Then $r($ $_1)$ is a d-line that passes through O and B . It follows that $r($ $_1) =$, so $_1$ must be the same as r $^{1}($ $) =$. This proves the uniqueness of the d-line through A and B.

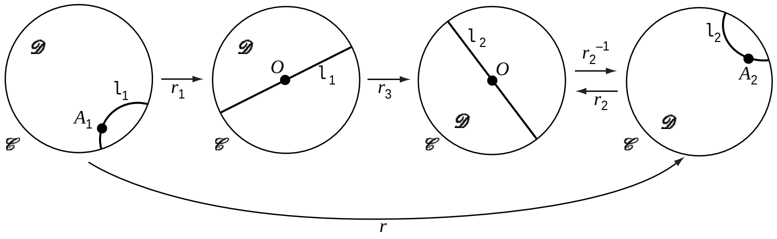
Problem 4 Let A_1 and A_2 be any two points of D. Use the Origin Lemma to prove that there is a hyperbolic transformation that maps A_1 to A_2.

In fact, we can establish a result stronger than that of Problem 4: we can determine a hyperbolic transformation which maps A_1 to A_2 *and* maps any given d-line through A_1 to any given d-line through A_2.

Theorem 5 Let A_1 and A_2 be any two points of D, and let $_1$ and $_2$ be d-lines through A_1 and A_2, respectively. Then there is a hyperbolic transformation which maps A_1 to A_2 and $_1$ to $_2$.

Proof By the Origin Lemma, there are hyperbolic transformations r_1 and r_2 which map A_1 and A_2, respectively, to the origin O. Let the images of $_1$ and $_2$ under r_1 and r_2 be the d-lines $_1$ and $_2$, respectively. Let r_3 be the hyperbolic transformation which rotates D about O so that $_1$ maps onto $_2$.

We shall verify in Subsection 6.2.1 that any rotation of D about O is a hyperbolic transformation.



Now let r be the hyperbolic transformation given by

$$r = r_2{}^{1} \quad r_3 \quad r_1.$$

Then r maps A_1 to A_2 and $_1$ to $_2$, as required.

Remark

We can choose the rotation r_3 to map the two parts of $_1$ O onto the two parts of $_2$ O in whichever way we please. Hence we can arrange for r to map the two parts of $_1$ A_1 onto the two parts of $_2$ A_2 in whichever way we please.

In the following example we show that parallel d-lines map to parallel d-lines under a hyperbolic transformation.

Example 1 Let A, B and C be points of C such that the d-lines AB and BC are parallel. Let r be a hyperbolic transformation under which the images of AB and BC are the d-lines $A\ B$ and $B\ C$, respectively, where A, B and C are points of C. Show that $A\ B$ and $B\ C$ are parallel d-lines.

Solution First, we show that $A\ B$ and $B\ C$ do not meet in D. If they do, let them meet at the point P, say. Then the point P corresponds to a point P, say, on the d-lines AB and BC; that is, $r\ {}^{1}(P) = P$. But there is no such point, since AB and BC are parallel; it follows that $A\ B$ and $B\ C$ do not meet in D.

Next, the generalized circles of which $A\ B$ and $B\ C$ are parts meet at a point B on C. So we conclude that the images of $A\ B$ and $B\ C$ are parallel d-lines. □

Note the convenient use of the label AB for a d-line even though A and B do not lie on that d-line (they lie on C). There is no ambiguity since there is only one circle through A and B with centre the point where the tangents to C at A and B meet. Analogously, we shall say that a d-line passes through its boundary points.

Problem 5 Show that, given a d-line and a point P not on , there are exactly two d-lines through P which are parallel to .
Hint: Use the Origin Lemma.

6.1.3 Inversion Preserves Inverse Points

Earlier, we proved the following result.

Subsection 5.5.2, Corollary 2

> Let A and B be inverse points with respect to a generalized circle C, and let t be an inversive transformation. Then $t(A)$ and $t(B)$ are inverse points with respect to the generalized circle $t(C)$.

We now consider a special case of this result, which we can interpret in terms of hyperbolic geometry.

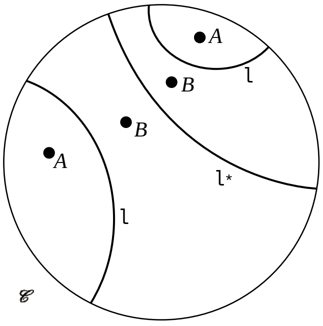
We take C to be a generalized circle of which part (a d-line) lies inside the unit disc $\mathbb{D}$. Let A be a point in $\mathbb{D}$; then its inverse with respect to , B say, is also in $\mathbb{D}$. We take t to be an inversion for which the generalized circle of inversion C^* is such that part (a d-line *) lies inside $\mathbb{D}$. Then, by the above result, $A \; = t(A)$ and $B \; = t(B)$ are inverse points in $\mathbb{D}$ with respect to the generalized circle $C \; = t(C)$, part of which lies in $\mathbb{D}$, namely the d-line $\; = t(\;)$.

See the diagram below.

Every inversion is an inversive transformation.

We now interpret this special case in terms of hyperbolic geometry.

Theorem 6 Let $A, B \quad \mathbb{D}$ be inverse points with respect to the d-line , and let A , B and be the images of A, B and under inversion (hyperbolic reflection) in another d-line *. Then A and B are inverse points with respect to inversion in .



Remark

Note the convenient use of the term inversion to mean hyperbolic reflection . This is consistent with the use of this term in Chapter 5.

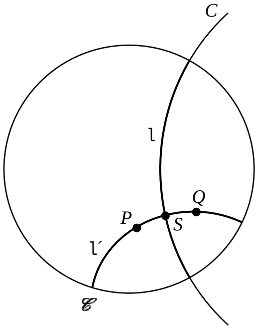
We shall make use of this theorem in Section 6.5, when we study the design on the cover of the book.

We finish this section with an illustration of the use of Theorem 6.

Example 2 Let be a d-line and P be a point in $\mathbb{D}$. Let Q be the image of P under inversion in the circle C of which is part. Let be the d-line through P and Q, meeting at the point S.

(a) Show that inversion in C maps to itself.

(b) Deduce that the d-lines and meet at right angles.



(c) Use Theorems 5 and 6 to show that there is a hyperbolic transformation mapping the figure to one in which the d-line is the x-axis and P and Q are complex conjugates.

Solution

(a) Inversion in C exchanges P and Q. So it maps , the unique d-line through P and Q, to itself.
(b) Inversion in C exchanges the angles makes with , and maps angles to angles of equal magnitude. So the angles must be equal, and since their sum is , each must be $/2$. Thus and meet at right angles.
(c) We use Theorem 5 to map the point S to O and the d-line to the x-axis. This makes the d-line part of the y-axis. By Theorem 6, P and Q are mapped to points that are inverse with respect to the x-axis, and so are complex conjugates of each other. □

6.2 Hyperbolic Transformations

6.2.1 Hyperbolic Transformations and Möbius Transformations

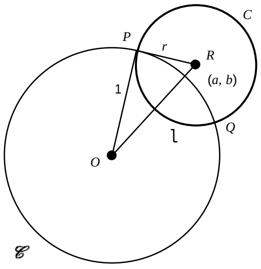
Each element of the group G_D of hyperbolic transformations is the composite of a finite number of reflections in d-lines. In this subsection we shall establish an explicit formula for a hyperbolic transformation in terms of Möbius transformations.

Subsection 5.3.3

We start by considering reflection in a d-line which is part of a circle C with centre the point R and radius r. Suppose that the d-line has boundary points P and Q. We let the coordinates of the point R be (a, b), and write the complex number $a + ib$ as , so that $| \; | > 1$ (which follows because is a d-line). We shall need the following observation: because the d-line is part of the circle with centre and radius r, the triangle RPO is right angled at P. So, by Pythagoras Theorem, $RP^2 + PO^2 = RO^2$. This implies that

We shall call this d-line the d-line obtained from .

$$r^2 + 1 = a^2 + b^2.$$



Using the fact that $a^2 + b^2 =$ fl, we may rewrite this equation as

$$r^2 \quad \text{fl} = \quad 1. \tag{1}$$

We now use equation (1), and the fact that inversion t in the circle C has the form

$$t(z) = \frac{r^2}{\overline{\overline{z}}} + \qquad (z \quad \mathrm{C} \quad \{ \; \}),$$

to obtain the form of the hyperbolic reflection in the d-line .

This follows from Subsection 5.2.1, Theorem 3.

Since is part of C, is given by

$$\begin{aligned} (z) &= \frac{r^2}{\overline{z}} + \\ &= \frac{r^2 + \bar{z} \quad \bar{}}{\bar{z} \quad \bar{}} \\ &= \frac{\bar{z} \quad 1}{\bar{z} \quad \bar{}} \quad (z \quad \mathbb{D}), \end{aligned}$$

by equation (1). Thus we have proved the following lemma.

Lemma 1 The hyperbolic reflection in the d-line that is part of a Euclidean circle with centre is given by the hyperbolic transformation

$$(z) = \frac{\bar{z} \quad 1}{\bar{z} \quad \bar{}} \qquad (z \quad \mathbb{D}).$$

Recall that $| \; | > 1$.

Notice that we may write

$$(z) = (M \quad B)(z), \qquad \text{for } z \quad \mathbb{D},$$

where $M(z) = \frac{z \quad 1}{z \quad \bar{}}$ is a Möbius transformation, and $B(z) = \bar{z}$ is complex conjugation. You know from Chapter 5 that Möbius transformations are important in inversive geometry: they preserve the magnitudes of angles, and they map generalized circles to generalized circles. Since angles and generalized circles are important in hyperbolic geometry, it is not surprising that particular sorts of Möbius transformations turn up here too.

Subsection 5.3.3, Theorem 5

Problem 1 Find the point which has image 0 under reflection in the d-line obtained from . Hence obtain a second proof of the Origin Lemma.

Reflection in a d-line which is a diameter of $\mathbb{D}$ is simply (Euclidean) reflection in that line. Recall that

Subsection 5.2.1

$$t_1(z) = \bar{z}$$

is reflection in the x-axis, and

$$t_2(z) = \quad z,$$

where $= \cos \quad + i \sin$ with $= \operatorname{Arg}$, is rotation about the origin through the angle . It follows that the composite

$$t_2 \quad t_1 \quad t_2^{\ 1} \quad (z) = \quad (\bar{z}) = \quad ^2\bar{z}$$

For $t_2^{\ 1}(z) = \bar{}z$

is reflection in the line with equation $y = x \tan$.

Thus hyperbolic reflection in the diameter on which $y = x \tan$ is given by

$$(z) = \quad ^2\bar{z} \qquad (z \quad \mathbb{D}),$$

where $= \cos \quad + i \sin$.

Example 1 Find the composite $_2 \quad _1$ of the hyperbolic reflections

$$_1(z) = {}^2\text{ﬂ}z \quad \text{and} \quad _2(z) = {}^2\text{ﬂ}z,$$

where $= \cos\ _1 + i \sin\ _1$ and $= \cos\ _2 + i \sin\ _2$, and interpret the transformation $_2 \quad _1$ geometrically.

Solution We have

$$(\ _2 \quad _1)(z) = {}^2\overline{(\ {}^2\text{ﬂ}z)} = {}^2\text{ﬂ}\,{}^2 z,$$

which is a Euclidean rotation about the origin of D. □

The composite of reflections and in two d-lines that are obtained from and , respectively, is found as follows. By Lemma 1, we have

$$(z) = \frac{\text{ﬂ}z \quad 1}{\text{ﬂ}z \quad \text{ﬂ}} = (M \quad B)(z)$$

Recall that $M(z) = \frac{z \quad 1}{z \quad \overline{\ }}$ and $B(z) = \text{ﬂ}z$.

and

$$(z) = \frac{\text{ﬂ}z \quad 1}{\text{ﬂ}z \quad \text{ﬂ}} = (M \quad B)(z),$$

where $M\ (z) = \frac{z \quad 1}{z \quad \text{ﬂ}}$ is a Möbius transformation. So

$$(\qquad)(z) = (M \quad B \quad M \quad B)(z).$$

But

$$(B \quad M)(z) = \frac{\overline{\ z} \quad 1}{\text{ﬂ}z} = (M \quad B)(z),$$

where $M(z)$ is the Möbius transformation $M(z) = \frac{\text{ﬂ}z \quad 1}{z}$. So

$$\begin{aligned}(\qquad)(z) &= (M \quad B \quad M \quad B)(z)\\ &= (M \quad M \quad B \quad B)(z) = (M \quad M)(z),\end{aligned}$$

because $(B \quad B)(z) = z$.

Now matrices associated with M and M are $\begin{pmatrix} & 1 \\ 1 & \text{ﬂ}\end{pmatrix}$ and $\begin{pmatrix}\text{ﬂ} & 1 \\ 1 & \end{pmatrix}$, respectively. Hence a matrix associated with the composite $M \quad M$ is

Here we are using the strategy in Subsection 5.3.5 for finding composites.

$$\begin{pmatrix} & 1 \\ 1 & \text{ﬂ}\end{pmatrix}\begin{pmatrix}\text{ﬂ} & 1 \\ 1 & \end{pmatrix} = \begin{pmatrix}\text{ﬂ} & 1 & \\ \text{ﬂ} & \text{ﬂ} & \text{ﬂ} \quad 1\end{pmatrix},$$

so that the composite of the hyperbolic reflections and is of the form

$$(\qquad)(z) = \frac{az + b}{\text{ﬂ}bz + \text{ﬂ}a},$$

where $a = \text{ﬂ} \quad 1, b = \quad$.

For ease of reference, we record this last result as a theorem.

Theorem 1 The composite of the hyperbolic reflections

$$(z) = \frac{\bar{z} \quad 1}{\bar{z} \quad \bar{\ }} \quad \text{and} \quad (z) = \frac{\bar{z} \quad 1}{\bar{z} \quad \bar{\ }} \qquad (z \quad D)$$

is the hyperbolic transformation

$$(\qquad)(z) = \frac{(\bar{\ } \qquad 1)z + \qquad}{(\bar{\ } \qquad \bar{\ })z + \quad \bar{\ } \quad 1} \qquad (z \quad D).$$

Example 2 Show that the hyperbolic reflection is its own inverse, by showing that $(\ (z)) = z$.

Solution From Theorem 1, we know that the composite of the reflection with itself is given by

$$(\qquad)(z) = \frac{(\bar{\ } \qquad 1)z + \qquad}{(\bar{\ } \quad \bar{\ })z + \quad \bar{\ } \quad 1} = \frac{(\bar{\ } \qquad 1)z}{\bar{\ } \quad 1} = z,$$

as required. □

$\bar{\ } = 1$ since $|\ | > 1$.

Example 3 Show that the composite $M_2 \quad M_1$ of the Möbius transformations

$$M_1(z) = \frac{az+b}{\bar{b}z+\bar{a}} \quad \text{and} \quad M_2(z) = \frac{cz+d}{\bar{d}z+\bar{c}}$$

is a Möbius transformation of the same form.

That is, of the form $\frac{ez+f}{\bar{f}z+\bar{e}}$, for some $e, f \quad$ C.

Solution By the strategy for finding composites of Möbius transformations, a matrix associated with the composite $M_2 \quad M_1$ is the matrix product

$$\begin{matrix} c & d \\ \bar{d} & \bar{c} \end{matrix} \qquad \begin{matrix} a & b \\ \bar{b} & \bar{a} \end{matrix} \quad = \quad \begin{matrix} ca+d\bar{b} & cb+d\bar{a} \\ \bar{d}a+\bar{c}\bar{b} & \bar{d}b+\bar{c}\bar{a} \end{matrix} \quad .$$

This product is of the required form, because

$$\overline{(ca+d\bar{b})} = \bar{d}b+\bar{c}\bar{a} \quad \text{and} \quad \overline{(cb+d\bar{a})} = \bar{d}a+\bar{c}\bar{b}.$$ □

It follows from this example that every composite of an even number of hyperbolic reflections in d-lines can be represented as a Möbius transformation, restricted to D, of the form

$$M(z) = \frac{az+b}{\bar{b}z+\bar{a}}, \quad z \quad D.$$

Similarly, it can be shown that every composite of an odd number of reflections can be represented as a Möbius transformation of this form composed with complex conjugation.

We omit the details of a proof of this.

It follows from the above discussion that any composite of a finite number of hyperbolic reflections, that is, any hyperbolic transformation, can be expressed in one of the forms

$$z \mapsto M(z) \quad \text{or} \quad z \mapsto M(\bar{z}) \quad (z \in \mathbb{D}),$$

where M is the Möbius transformation

$$M(z) = \frac{az+b}{\bar{b}z+\bar{a}}, \quad z \in \mathbb{D}.$$

Moreover, since $M(0) = b/\bar{a}$ and the image of 0 under a hyperbolic transformation must be in $\mathbb{D}$, we require that the above Möbius transformation must be such that

$$|b| < |a|.$$

The remaining question is: Do all such Möbius transformations represent hyperbolic transformations? In fact the answer is YES, as the following theorem shows.

Theorem 2 The restriction to $\mathbb{D}$ of every Möbius transformation of the form $M(z) = \frac{az+b}{\bar{b}z+\bar{a}}$ with $|b| < |a|$ is a composite of two hyperbolic reflections, and is therefore a hyperbolic transformation.

When the context is clear, we often omit to say that the Möbius transformation we are considering is restricted to $\mathbb{D}$.

The proof is a little devious (and no less elegant for that). We first prove it for the special case when the Möbius transformation maps the origin to itself. Using this special case, we then prove the general case.

Proof

Case 1 The Möbius transformation $M(z) = \frac{az+b}{\bar{b}z+\bar{a}}$ maps the origin to itself.

We shall show that M is the composite of two reflections.

The condition $M(0) = 0$ implies that $b = 0$, so that the Möbius transformation is simply $M(z) = \frac{a}{\bar{a}}z$ — a rotation about the origin.

Now, if we let $a = re^{i\theta}$, then

$$\frac{a}{\bar{a}} = e^{2i\theta}.$$

So, if we let σ_1 and σ_2 be the reflections in diameters of $\mathbb{D}$ given by

$$\sigma_1(z) = \bar{z}, \quad z \in \mathbb{D}, \quad \text{and} \quad \sigma_2(z) = e^{2i\theta}\,\bar{z}, \quad z \in \mathbb{D},$$

then

$$\sigma_2 \circ \sigma_1(z) = e^{2i\theta}\,\overline{(\bar{z})} = e^{2i\theta}z,$$

so that $M = \sigma_2 \circ \sigma_1$, as required.

Recall that reflection in the diameter $y = x\tan\theta$ of $\mathbb{D}$ is a mapping of the form $z \mapsto \lambda^2\bar{z}$, where $\lambda = e^{i\theta} = \cos\theta + i\sin\theta$ and $z \in \mathbb{D}$.

Case 2 The Möbius transformation $M(z) = \frac{az+b}{\bar{b}z+\bar{a}}$ does not map the origin to itself.

We shall again show that M is the composite of two hyperbolic reflections.

Consider a hyperbolic transformation φ given by $\varphi(z) = (M \circ B)(z)$, where $M\ (z) = \frac{z \quad 1}{z \quad \bar{\ }}$ is a Möbius transformation, and $B(z) = \bar{z}$ is complex conjugation. We shall choose so as to make φ and $M \circ \varphi$ hyperbolic reflections. This will show that $M = (M \circ \varphi) \circ \varphi^{-1}$ is a composite of two hyperbolic reflections.

Since M and M_λ are associated with the matrices

$$\begin{pmatrix} a & b \\ \bar{b} & \bar{a} \end{pmatrix} \quad \text{and} \quad \begin{pmatrix} \lambda & -1 \\ 1 & -\bar{\lambda} \end{pmatrix},$$

respectively, the composite $M \circ M_\lambda$ is associated with the matrix

$$\begin{pmatrix} a & b \\ \bar{b} & \bar{a} \end{pmatrix} \begin{pmatrix} \lambda & -1 \\ 1 & -\bar{\lambda} \end{pmatrix} = \begin{pmatrix} a\lambda + b & -(\bar{\lambda} b + a) \\ \lambda\bar{b} + \bar{a} & -\bar{b} - \bar{a}\bar{\lambda} \end{pmatrix},$$

so we deduce that

$$(M \circ M_\lambda \circ B)(z) = \frac{(a\lambda + b)\bar{z} - (\bar{\lambda} b + a)}{(\lambda\bar{b} + \bar{a})\bar{z} - \bar{b} - \bar{a}\bar{\lambda}}.$$

Now since $M(0) \neq 0$, it follows that $b \neq 0$. Hence we may choose $\lambda = -\overline{(a/b)}$, so that

$$\bar{\lambda} b + a = -(a/b)b + a = 0.$$

For, σ is of the form required by Lemma 1.

Next, since $|b| < |a|$, we deduce that $|\lambda| = \frac{|a|}{|b|} > 1$, and so the transformation $\sigma = M_\lambda \circ B$ is a hyperbolic reflection as required. Moreover,

$$(M \circ \sigma)(z) = (M \circ M_\lambda \circ B)(z) = \frac{(a\lambda + b)\bar{z}}{-\bar{b} - \bar{a}\bar{\lambda}}$$

is of the form $-\frac{\mu}{\bar{\mu}}\bar{z}$, where $\mu = a\lambda + b$, and so the transformation $M \circ \sigma$ is a hyperbolic reflection. It follows that the transformation M is a composite of two hyperbolic reflections, $M \circ \sigma$ and σ^{-1}.

A similar argument shows that the more general transformation

$$z \mapsto \frac{a\bar{z} + b}{\bar{b}\bar{z} + \bar{a}}$$

is a composite of three reflections. For it is the composite $(M \circ B)(z)$ of the Möbius transformation

$$M(z) = \frac{az + b}{\bar{b}z + \bar{a}}$$

with complex conjugation $B(z) = \bar{z}$. Now, the Möbius transformation M is a composite of two reflections, and complex conjugation B is reflection in the x-axis. So $M \circ B$ is a composite of three reflections, as claimed.

Putting together all the above results, we have shown the following.

Theorem 3 Every hyperbolic transformation can be written as a composite of at most three hyperbolic reflections.

Example 4 Show that the composite $\sigma_2 \circ \sigma_1$ of the two reflections in lines through the origin given by $\sigma_1(z) = \alpha^2\bar{z}$ and $\sigma_2(z) = \beta^2\bar{z}$ can be written in the form $M(z) = \frac{az+b}{\bar{b}z+\bar{a}}$.

Solution From Example 1, we know that

$$(\ {}_2\ \ {}_1)(z) = {}^2\text{fl}^2 z.$$

Since $|\ | = 1$ and $|\ | = 1$,

$${}^1 = \text{fl} \quad \text{and} \quad {}^1 = \text{fl},$$

and so

$$(\ {}_2\ \ {}_1)(z) = M(z),$$

where

$$M(z) = \frac{az + b}{\text{fl}bz + \text{fl}a} \quad \text{with } a = \ \text{fl} \text{ and } b = 0. \qquad \square$$

Problem 2 Let $M(z) = \frac{az+b}{\text{fl}bz+\text{fl}a}$ be a hyperbolic transformation mapping the origin to itself. Show that $b = 0$.

Hyperbolic Rotations and Translations

It follows from the Angle Theorem of inversive geometry that a single hyperbolic reflection reverses the orientation of angles between d-lines. So a composite of two such transformations leaves the orientation unchanged, while a composite of three reverses it again. We call a hyperbolic transformation that leaves orientation unchanged a **direct** hyperbolic transformation, and one that reverses orientation **indirect.** So, by Theorem 3 above, we deduce that

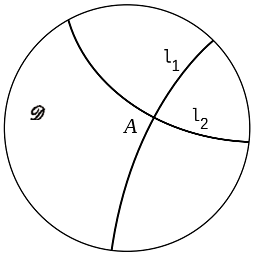
Subsection 5.1.3, Theorem 5

> a direct hyperbolic transformation can be written as a composite of at most two hyperbolic reflections

Theorem 1 gives the form of a composite of two reflections.

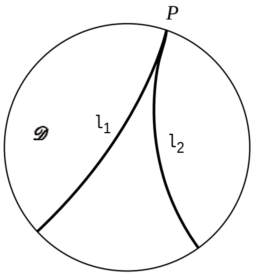
and

> an indirect hyperbolic transformation can be written as a composite of at most three hyperbolic reflections.



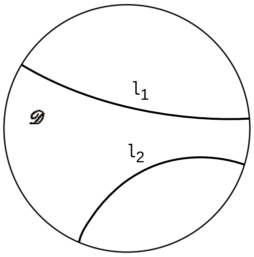
It is possible to say more about the direct transformations. Let r_1 and r_2 be reflections in the d-lines ${}_1$ and ${}_2$, respectively.

First, suppose that ${}_1$ and ${}_2$ intersect at some point A. (Certainly they cannot intersect at more than one point if they are distinct d-lines, since by Theorem 4 of Subsection 6.1.2 there is a unique d-line through any two points of D.) Then the composition $r_2\ \ r_1$ leaves the point A fixed, moves the points of D around A, and does not alter the orientation of D. Such a hyperbolic transformation is called a **(hyperbolic) rotation,** and has exactly one fixed point in D.



Next, suppose that the d-lines ${}_1$ and ${}_2$ are parallel, that is, the generalized circles of which they are parts do not meet in D but do meet at some point P on C. Then the composite $r_2\ \ r_1$ moves the points of D around P, and does not alter the orientation of D; it has no fixed point in D, but it leaves all the parallel lines with P as their common boundary point as parallel lines ending at P. We can regard this as the limiting case of a rotation (about a point of $\mathcal{C}$), and so call it a **(hyperbolic) limit rotation.**

Finally, suppose that the d-lines ℓ_1 and ℓ_2 are ultra-parallel, that is, the generalized circles of which they are parts do not meet in $\mathcal{D}$ or on $\mathcal{C}$. Then the composite $r_2 \circ r_1$ moves all the points of $\mathcal{D}$ in one general direction, and does not alter the orientation of $\mathcal{D}$; but no point of $\mathcal{D}$ (or $\mathcal{C}$) remains fixed. Such a hyperbolic transformation is called a **(hyperbolic) translation.**



The analogy between Euclidean geometry and hyperbolic geometry is not exact, however. For instance, the composite of two Euclidean translations is independent of the order in which they are applied, whereas the composite of two hyperbolic translations may not be independent of the order in which they are applied.

6.2.2 The Canonical Form of a Hyperbolic Transformation

In this subsection we show how to write a hyperbolic transformation in the most suitable form for applications. We shall do this only for a direct transformation of the form $M(z) = \frac{az+b}{\bar{b}z+\bar{a}}$, where $|b| < |a|$. Our result is the following theorem.

Theorem 4 A direct hyperbolic transformation M can be written in the form

$$M(z) = K\frac{z-m}{1-\bar{m}z},$$

where K and m are complex numbers with $|K| = 1$ and $m \in \mathcal{D}$.

Remark

We call this form the **canonical form** of a direct hyperbolic transformation. It has the great advantage of showing that the transformation M maps the point m to the origin.

Proof We know from the previous subsection that a direct hyperbolic transformation can always be written in the form

$$M(z) = \frac{az+b}{\bar{b}z+\bar{a}}, \quad \text{with } |b| < |a|.$$

See the discussion before Theorem 2.

Indeed, on dividing the expression for $M(z)$ above and below by $\bar{a}$, we can write it as

$$M(z) = \frac{\frac{a}{\bar{a}}z + \frac{b}{\bar{a}}}{1-\left(-\frac{\bar{b}}{\bar{a}}\right)z} = \frac{a}{\bar{a}}\left(\frac{z-\left(-\frac{b}{a}\right)}{1-\left(-\frac{\bar{b}}{\bar{a}}\right)z}\right),$$

which is of the required form, with $K = a/\bar{a}$ and $m = -b/a$. Since $|a| = |\bar{a}|$, it follows that $|K| = 1$, as required. Since $|b| < |a|$, it follows that $|m| < 1$, as required.

We can now find the form of every direct hyperbolic transformation that maps a point m of D to the origin. We know from Theorem 4 that it must be of the form

$$M(z) = K\frac{z \quad m}{1 \quad \overline{m\ } z}, \qquad \text{where } |K| = 1 \text{ and } |m\ | < 1.$$

The condition that $M(m) = 0$ implies that $m\ = m\ $, so we deduce that in fact *every* direct hyperbolic transformation mapping the point m to the origin is of the form

$$M(z) = K\frac{z \quad m}{1 \quad \overline{m}z}.$$

The direct hyperbolic transformations that map the origin to itself are therefore those for which $m\ = 0$, so they are of the form $M(z) = Kz$ with $|K| = 1$. These are (Euclidean) rotations of the disc D about the origin through an angle , where $K = \cos \quad + i \sin$. In general, if all that is required is just one direct hyperbolic transformation sending a given point m to the origin, then we may set $K = 1$, and use the transformation $M(z) = \frac{z \quad m}{1 \quad \overline{m}z}$.

$K = 1$ is the most convenient value to choose.

Example 5

(a) Find the general form of a direct hyperbolic transformation that maps the point $\frac{1}{2}i$ to the origin.
(b) Find one direct hyperbolic transformation that maps $\frac{3}{4}$ to the origin.

Solution

(a) The general form is

$$M(z) = K\frac{z \qquad \frac{1}{2}i}{1 \qquad \frac{1}{2}i \quad z} = K\frac{2z \quad i}{iz + 2}, \qquad \text{where } |K| = 1.$$

(b) Taking $K = 1$ in the formula of Theorem 4, as suggested above, one such transformation is

$$M(z) = \frac{z \quad \frac{3}{4}}{1 \quad \frac{3}{4}z}. \qquad \square$$

Problem 3 Determine all the direct hyperbolic transformations that map the origin to the origin and the line $y = x/\quad \overline{3}$ to the line $y = \quad \overline{3}x$.

Problem 4 For each of the following points, determine all the direct hyperbolic transformations that map it to the origin.
(a) $\frac{1}{4}i$ (b) $\quad \frac{1}{3} + \frac{2}{3}i$

The general form of the inverse of a direct hyperbolic transformation M mapping the point m to the origin is a direct hyperbolic transformation sending the origin to m. To find this inverse explicitly, we write

$$\begin{aligned} M(z) &= K\frac{z - m}{1 - \overline{m}z} \quad \text{(by Theorem 4)} \\ &= \frac{Kz - Km}{-\overline{m}z + 1}, \end{aligned}$$

and make use of the fact that M is the restriction to $\mathbb{D}$ of a Möbius transformation to write

$$M^{-1}(z) = \frac{z + Km}{\overline{m}z + K}, \tag{2}$$

where $|K| = 1$.

By restriction to $\mathbb{D}$ we mean that we only consider those z in $\mathbb{D}$.

This form for M^{-1} follows immediately from Subsection 5.3.6, Theorem 7.

Problem 5 Determine the general form of the inverse of the direct hyperbolic transformation M which maps $\frac{3}{4}$ to the origin.

Problem 6 Prove that any direct hyperbolic transformation M that maps the diameter $(-1, 1)$ onto itself must be of the form

$$M(z) = -\frac{z - m}{1 - mz}, \qquad \text{where } m \in (-1, 1).$$

Since an *indirect* hyperbolic transformation can be written as the composite of at most three reflections, it follows that the general form of such a transformation is

$$z \mapsto \frac{a\overline{z} + b}{\overline{b}\overline{z} + \overline{a}}.$$

See the discussion preceding Theorem 2.

An argument similar to that for direct transformations shows that this transformation can always be written in the form

$$z \mapsto K\frac{\overline{z} - m}{1 - \overline{m}\overline{z}}, \qquad \text{where } |k| = 1 \text{ and } |m| < 1.$$

We call this form the **canonical form** of an indirect hyperbolic transformation.

Theorem 4 gives the general form of a direct hyperbolic transformation that maps a given point m in $\mathbb{D}$ to the origin. By two applications of the theorem, therefore, we can obtain the general form of a direct hyperbolic transformation that maps any given point in $\mathbb{D}$ to any other given point in $\mathbb{D}$.

If we require a particular direct transformation that maps p to q, then we may choose a particular M_1 and a particular $\mathbf{A}_1$.

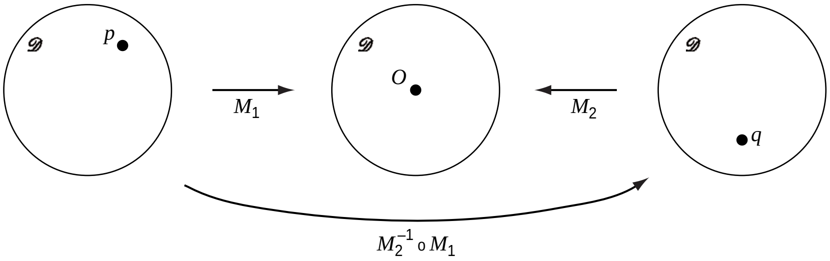
The constant arising in Step 1 means that it is sufficient to use any particular transformation in Step 2, since the final general transformation requires only one constant.

Strategy To determine the general form of the direct hyperbolic transformation that maps one point p in $\mathbb{D}$ to another point q in $\mathbb{D}$:

1. write down the general form of the direct transformation M_1 that maps p to 0, and a matrix $\mathbf{A}_1$ associated with M_1;
2. write down a direct transformation M_2 that maps q to 0, and a matrix $\mathbf{A}_2$ associated with M_2;

3. form the matrix product $\mathbf{A}_2^{-1}\mathbf{A}_1$ associated with the direct transformation $M_2^{-1} \circ M_1$, and hence write down the general form of the required direct transformation $M_2^{-1} \circ M_1$.

The following figure illustrates this strategy.



Example 6 Determine the general form of the direct hyperbolic transformation that maps $\frac{1}{2}i$ to $\frac{3}{4}$.

Solution We have already seen that the general form of the direct hyperbolic transformation M_1 that maps $\frac{1}{2}i$ to 0 is

Example 5, part (a).

$$M_1(z) = K\frac{2z - i}{iz + 2}, \qquad \text{where } |K| = 1;$$

a matrix associated with M_1 is

$$\mathbf{A}_1 = \begin{pmatrix} 2K & -iK \\ i & 2 \end{pmatrix}.$$

Also, the direct transformation

$$M_2(z) = \frac{z - \frac{3}{4}}{1 - \frac{3}{4}z}$$

Example 5, part (b).

maps $\frac{3}{4}$ to 0; a matrix associated with M_2 is

$$\mathbf{A}_2 = \begin{pmatrix} 1 & -\frac{3}{4} \\ -\frac{3}{4} & 1 \end{pmatrix}.$$

The inverse of $\mathbf{A}_2$ is

$$\mathbf{A}_2^{-1} = \tfrac{16}{7}\begin{pmatrix} 1 & \frac{3}{4} \\ \frac{3}{4} & 1 \end{pmatrix}.$$

So a matrix associated with the required direct transformation is

$$\begin{aligned} \mathbf{A}_2^{-1}\mathbf{A}_1 &= \tfrac{16}{7}\begin{pmatrix} 1 & \frac{3}{4} \\ \frac{3}{4} & 1 \end{pmatrix}\begin{pmatrix} 2K & -iK \\ i & 2 \end{pmatrix} \\ &= \tfrac{4}{7}\begin{pmatrix} 8K + 3i & -4iK + 6 \\ 6K + 4i & -3iK + 8 \end{pmatrix}. \end{aligned}$$

Hence any direct transformation that maps $\frac{1}{2}i$ to $\frac{3}{4}$ may be written in the form

The fraction $\frac{4}{7}$ disappears at this point, as it is simply a multiple of the whole matrix.

$$M(z) = \frac{(8K + 3i)z + (-4iK + 6)}{(6K + 4i)z + (-3iK + 8)}, \qquad \text{where } |K| = 1. \qquad \square$$

Problem 7

(a) Determine the general form of the direct hyperbolic transformation that maps $\frac{1}{3}i$ to $\frac{2}{3}$.
(b) Determine the direct hyperbolic transformation that also maps i to 1.

Problem 8 Determine the general form of the direct hyperbolic transformation that maps $\frac{1}{2}$ to $\frac{1}{2}$.

These functions fix the point $\frac{1}{2}$.

Problem 9 For each of the following pairs of points, either find a direct hyperbolic transformation mapping the first point to 0 and the second point to $\frac{1}{2}$, or prove that no such transformation exists.

(a) $\frac{1}{2}i$ and 0 (b) $\frac{1}{2}$ and $\frac{2}{3}$ (c) $\frac{1}{3}(1+i)$ and $\frac{1}{3}(1-i)$.

6.3 Distance in Hyperbolic Geometry

In the Euclidean geometry of the plane, corresponding to any two points there exists a non-negative number called the distance between the points. This is given by the formula

$$d(z_1, z_2) = |z_1 - z_2|, \quad z_1, z_2 \in \mathbb{C}.$$

So $d(z_1, z_2) = d(z_2, z_1)$.

In this section, we introduce an analogous formula for the distance in hyperbolic geometry between any two points of the unit disc $\mathbb{D}$.

6.3.1 The Distance Formula

We begin by looking at various properties that we would expect any distance function d to have in any geometry whose points lie in the complex plane $\mathbb{C}$. Ordinary Euclidean distance, for example, clearly possesses the following four properties.

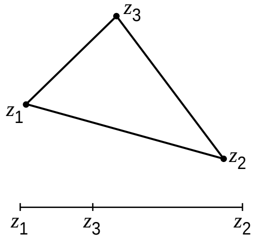
Properties of a Distance Function *d*

1. $d(z_1, z_2) \geq 0$ for all z_1 and z_2;
   $d(z_1, z_2) = 0$ if and only if $z_1 = z_2$.
2. $d(z_1, z_2) = d(z_2, z_1)$ for all z_1 and z_2.
3. $d(z_1, z_3) + d(z_3, z_2) \geq d(z_1, z_2)$ for all z_1, z_2 and z_3.
4. $d(z_1, z_3) + d(z_3, z_2) = d(z_1, z_2)$ if and only if z_1, z_3 and z_2 lie in this order on a line.

Property 3 is known as the *Triangle Inequality.*

Property 1 asserts that the distance between any two points in the geometry is always positive, unless the two points coincide — in which case the distance between them must be zero.

Property 2 asserts that the distance from z_1 to z_2 is the same as the distance from z_2 to z_1.



Property 3 asserts that the distance from z_1 to z_2 is always less than (or equal to) the distance from z_1 to another point z_3 plus the distance from z_3 to z_2. In Euclidean geometry this property may be rewritten in the form

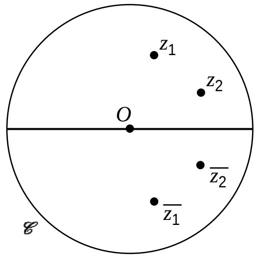
$$|z_1 - z_3| + |z_3 - z_2| \geq |z_1 - z_2|.$$

Property 4 asserts that distance along a line is additive.

However, there are some additional properties that we wish the distance function in hyperbolic geometry to possess.

Additional Properties of the Distance Function *d* in Hyperbolic Geometry

5. $d(z_1, z_2) = d(\bar{z}_1, \bar{z}_2)$ for all z_1 and z_2 in $\mathbb{D}$.
6. $d(z_1, z_2) = d(M(z_1), M(z_2))$ for all z_1 and z_2 in $\mathbb{D}$ and all direct hyperbolic transformations M in $G_{\mathbb{D}}$.



Properties 5 and 6 together assert that hyperbolic transformations of the unit disc $\mathbb{D}$ do not alter distances between points, since a hyperbolic transformation is either a direct transformation of the unit disc to itself (as in Property 6) or the composite of such a function with the conjugation function $z \mapsto \bar{z}$ (which, by Property 5, preserves distance).

These additional properties enable us to make some useful observations about the form of the distance function. First, the direct hyperbolic transformation

$$M : z \mapsto \frac{z - z_1}{1 - \bar{z}_1 z}, \quad \text{where } z_1 \in \mathbb{D},$$

maps z_1 to 0 and z_2 to $\frac{z_2 - z_1}{1 - \bar{z}_1 z_2}$. If R is the rotation of the unit disc $\mathbb{D}$ about the origin which sends $\frac{z_2 - z_1}{1 - \bar{z}_1 z_2}$ to the point $\left|\frac{z_2 - z_1}{1 - \bar{z}_1 z_2}\right|$, then overall the composite $R \circ M$ is a direct hyperbolic transformation which sends z_1 to 0 and z_2 to $\left|\frac{z_2 - z_1}{1 - \bar{z}_1 z_2}\right|$.

Recall that any rotation of $\mathbb{D}$ about the origin is a direct hyperbolic transformation (Subsection 6.2.1).

By Property 6 it follows that

$$d(z_1, z_2) = d\left(0, \left|\frac{z_2 - z_1}{1 - \bar{z}_1 z_2}\right|\right), \quad \text{for all } z_1, z_2 \in \mathbb{D}.$$

This shows that the distance $d(z_1, z_2)$ must be some function of the quantity $\left|\frac{z_2 - z_1}{1 - \bar{z}_1 z_2}\right|$ alone. But what function ensures that d has the Properties 1-6 above? Indeed, does such a function exist? In fact, there is essentially only one well-behaved function which yields these properties, and it turns out to be the function $\tanh^{-1}$.

We verify this assertion in Subsection 6.3.5.

Definition The **hyperbolic distance** $d(z_1, z_2)$ between the points z_1 and z_2 in the unit disc $\mathbb{D}$ is defined by

$$d(z_1, z_2) = \tanh^{-1}\left(\left|\frac{z_2 - z_1}{1 - \bar{z}_1 z_2}\right|\right).$$

Of course before we can be sure that this is a reasonable definition of distance we need to check that d satisfies all the Properties 1–6. Clearly d satisfies Properties 1, 2, 5, and we shall prove the other properties later in this section; for the moment we assume that all the properties hold, and we use them to explore some of the practical consequences of the definition.

First observe that the formula for the distance between two given points is particularly simple in the case where one of the points lies at the origin. Indeed we have

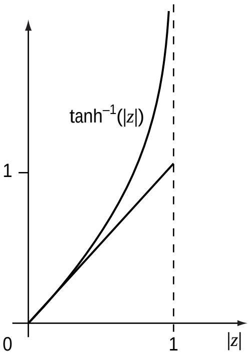
Definition The **hyperbolic distance** $d(0,z)$ between the points 0 and z in the unit disc $\mathbb{D}$ is

$$d(0,z) = \tanh^{-1}(|z|).$$

Since this formula is simpler to remember, we shall tend to use it more often than the formula for $d(z_1, z_2)$!

Since $|z|$ is just the Euclidean distance of z from the origin, this equation tells us that we can obtain the hyperbolic distance of a point z from the origin by applying the inverse tanh function to the Euclidean distance of z from the origin. The graph of the inverse tanh function in the margin reveals two important characteristics of hyperbolic distance.

1. Near the origin the graph is nearly a straight line with slope 1, so for a point z near the origin the hyperbolic distance of z from 0 is approximately equal to the Euclidean distance of z from 0. (This is analogous to the situation on the surface of the Earth; small portions of the Earth's surface *look* flat and distances between its points are *approximately* Euclidean.)
2. As the point z approaches the boundary of the disc $\mathbb{D}$, the hyperbolic distance of z from the origin increases without bound. Indeed, as the Euclidean distance $|z|$ tends to 1, the hyperbolic distance $\tanh^{-1}(|z|)$ tends to ∞. From the point of view of someone living in the hyperbolic geometry, the boundary points appear to be infinitely far away—an observation that is consistent with the idea that parallel lines 'meet' on the boundary.



With the help of a calculator we can easily use the formula

$$d(0,z) = \tanh^{-1}(|z|) \tag{1}$$

to calculate the hyperbolic distance of a point from the origin.

At the end of this subsection we prove the alternative formula

$$d(0,z) = \tfrac{1}{2}\log_e\left(\frac{1+|z|}{1-|z|}\right)$$

which you can use if your calculator does not have a tanh function.

For example, the hyperbolic distance of $\frac{1}{2}$ from the origin is given by

$$d\left(0,\tfrac{1}{2}\right) = \tanh^{-1}\left(\frac{1}{2}\right) = \tanh^{-1}(0.5) \simeq 0.549.$$

But we can also use equation (1) to calculate the hyperbolic distance between any two points which lie on a diameter of the disc $\mathbb{D}$.

Example 1 Find the hyperbolic distance between the points 0.1 and 0.2.

Solution Here we use Property 4, which states that distances along a (hyperbolic) line are additive. In particular, this implies that

$$d(0.1, 0.2) = d(0, 0.2) \quad d(0, 0.1),$$

so we can write

$$\begin{aligned} d(0.1, 0.2) &= d(0, 0.2) \quad d(0, 0.1) \\ &= \tanh\ ^{1}(0.2) \quad \tanh\ ^{1}(0.1) \\ & \quad 0.203 \quad 0.100 \\ & \quad 0.102. \end{aligned}$$

□

Throughout Section 6.3 we shall work to the full accuracy of our calculator, but we shall record our results only to 3 or 4 decimal places.

Problem 1 Determine the hyperbolic distances $d \quad 0, \tfrac{1}{3}i$ and $d(0.8, 0.9)$.

By rearranging equation (1) we obtain the formula

$$|z| = \tanh d(0, z). \tag{2}$$

This can be used to locate a point, given its hyperbolic distance along a radius of the disc D. For example, the point a that is at a hyperbolic distance 0.1 from the origin along the positive real axis is given by $a = \tanh 0.1 \quad 0.0997$.

Problem 2 The following table (plotted in the margin) illustrates how points bunch up towards the boundary of D as their hyperbolic distance from 0 doubles.

Find the two missing entries in the table.

$d(0, a), a > 0$	0.2	0.4	0.8	1.6	3.2
a	0.197 . . .	0.380 . . .	0.664 . . .		

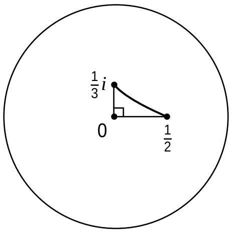
If we have to calculate the distance between two points that do not lie on a diameter of D, then we can use the distance formula given in the definition.

Example 2 Find the hyperbolic distance between the points $\tfrac{1}{2}$ and $\tfrac{1}{3}i$.

Solution From the definition of hyperbolic distance we have

$$\begin{aligned} d \quad \tfrac{1}{2}, \tfrac{1}{3}i &= \tanh\ ^{1} \quad \frac{\tfrac{1}{2} \quad \tfrac{1}{3}i}{1 \quad \overline{\tfrac{1}{3}i} \bullet \tfrac{1}{2}} \\ &= \tanh\ ^{1} \quad \frac{3 \quad 2i}{6 + i} \\ &= \tanh\ ^{1} \quad \overline{\tfrac{13}{37}} \\ & \quad 0.6819. \end{aligned}$$

□



We can use the distances that we have calculated above to demonstrate that Pythagoras' Theorem fails to hold in hyperbolic geometry, at least without some rewording. For, if we consider the hyperbolic right-angled triangle with vertices at 0, $\frac{1}{3}i$ and $\frac{1}{2}$, then the square of the hypotenuse is

$$\left(d\left(\tfrac{1}{2}, \tfrac{1}{3}i\right)\right)^2 \simeq 0.6819^2 \simeq 0.4650,$$

whereas the sum of the squares of the other two sides is

$$\left(d\left(0, \tfrac{1}{2}\right)\right)^2 + \left(d\left(0, \tfrac{1}{3}i\right)\right)^2 \simeq 0.5493^2 + 0.3466^2 \simeq 0.4219.$$

We evaluated $d\left(0, \frac{1}{2}\right)$ before Example 1, and $d\left(0, \frac{1}{3}i\right)$ in Problem 1.

We shall see later on how Pythagoras' Theorem can be reformulated in hyperbolic geometry.

Subsection 6.4.3, Theorem 8

We end this subsection by giving an alternative formula for the hyperbolic distance of a point z from the origin. First, observe that

$$\begin{aligned} |z| &= \tanh d(0,z) \\ &= \frac{\sinh d(0,z)}{\cosh d(0,z)} \\ &= \frac{e^{d(0,z)} - e^{-d(0,z)}}{e^{d(0,z)} + e^{-d(0,z)}} \\ &= \frac{e^{2d(0,z)} - 1}{e^{2d(0,z)} + 1}. \end{aligned}$$

We can solve this equation to obtain an expression for $d(0,z)$ in terms of $|z|$. By cross-multiplication, we obtain

$$e^{2d(0,z)} - 1 = |z|\left(e^{2d(0,z)} + 1\right),$$

which implies that

$$e^{2d(0,z)}(1 - |z|) = 1 + |z|,$$

which is equivalent to

$$e^{2d(0,z)} = \frac{1 + |z|}{1 - |z|}.$$

Taking natural logarithms of both sides, we deduce that

$$2d(0,z) = \log_e\left(\frac{1 + |z|}{1 - |z|}\right),$$

and so

$$d(0,z) = \frac{1}{2}\log_e\left(\frac{1 + |z|}{1 - |z|}\right). \qquad (3)$$

This formula is useful if your calculator does not have a tanh function.

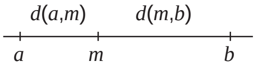
The formula for $d(0,z)$ is sometimes quoted in this form.

6.3.2 Hyperbolic Midpoints

Having described how to calculate hyperbolic distances we now introduce the idea of the hyperbolic midpoint of a hyperbolic line segment.

Definition A point m is the **hyperbolic midpoint** of the hyperbolic line segment joining a and b if m lies on this segment and

$$d(a,m) = d(m,b) = \frac{1}{2}d(a,b).$$



For simplicity, we confine our attention to midpoints of line segments that lie along a diameter of $\mathbb{D}$. The method depends on whether the endpoints of the segment lie on the same side of the origin O, or on opposite sides of O.

Example 3 Find the hyperbolic midpoint m of the line segment which joins each of the following pairs of points.

(a) $\frac{1}{4}i$ and $\frac{3}{4}i$ (b) $\frac{1}{4}i$ and $\frac{3}{4}i$

Solution First observe that

$$d\ \ 0, \tfrac{1}{4}i \ \ = \tanh^{\ 1}\ \ \tfrac{1}{4}i \ \ = \tanh^{\ 1}(0.25) = 0.255\ldots,$$

and

$$d\ \ 0, \tfrac{3}{4}i \ \ = \tanh^{\ 1}\ \ \tfrac{3}{4}i \ \ = \tanh^{\ 1}(0.75) = 0.973\ldots.$$

(a) Here $\frac{3}{4}i$ and $\frac{1}{4}i$ lie on the same side of 0, so the midpoint must lie at a hyperbolic distance

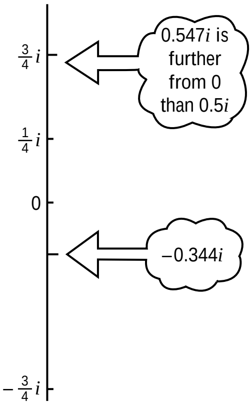
$$\tfrac{1}{2}\ \ d\ \ 0, \tfrac{3}{4}i \ \ + d\ \ 0, \tfrac{1}{4}i \qquad \tfrac{1}{2}(0.973 + 0.255) = 0.614$$

from 0 on the radius through $\frac{3}{4}i$. That is, $m \quad (\tanh 0.614)i \quad 0.547i$. (Notice that this is further from 0 than the Euclidean midpoint $0.5i$.)

(b) Here $\frac{3}{4}i$ and $\frac{1}{4}i$ lie on opposite sides of 0, so the midpoint lies at a hyperbolic distance

$$\tfrac{1}{2}\ \ d\ \ 0, \quad \tfrac{3}{4}i \qquad d\ \ 0, \tfrac{1}{4}i \qquad \tfrac{1}{2}(0.973 \quad 0.255) = 0.359$$

from 0 on the radius through $\frac{3}{4}i$. That is, $m \quad (\tanh 0.359)i \quad 0.344i$. □



The following strategy generalizes the method used in Example 3.

Strategy To find the hyperbolic midpoint of a line segment joining two points p, q on a diameter of $\mathbb{D}$, where $|p| > |q|$:

1. calculate $d(0, p)$ and $d(0, q)$;
2. if p and q lie on opposite sides of 0, then calculate

$$d = \tfrac{1}{2}(d(0,p) \quad d(0,q)),$$

otherwise calculate

$$d = \tfrac{1}{2}(d(0,p) + d(0,q));$$

3. then the hyperbolic midpoint is the point m on the radius through 0 and p at a Euclidean distance $\tanh(d)$ from 0.

Problem 3 Find the hyperbolic midpoint m of the line segment which joins each of the following pairs of points:

0.5 and 0.8; 0.2 and 0.8.

Remark

To calculate the hyperbolic midpoint of a line segment which joins two *arbitrary* points p, q in $\mathbb{D}$ we would use a Möbius transformation M to map p to 0 and q to $M(q)$. After calculating the hyperbolic midpoint m' of the segment from 0 to $M(q)$, we would then obtain the midpoint of the original segment by calculating $M^{-1}(m')$.

6.3.3 Hyperbolic Circles

By analogy with Euclidean circles, we define a hyperbolic circle to be the locus of points which are a fixed hyperbolic distance from a fixed point.

Definition The **hyperbolic circle** with **hyperbolic radius** r and **hyperbolic centre** at c is the set defined by

$$\{z : d(c,z) = r, \quad z \in \mathbb{D}\}.$$

It is natural to ask what a hyperbolic circle looks like to the Euclidean eye. In the case of a hyperbolic circle with radius r centred at the origin, it is just the set of points given by

$$\{z : d(0,z) = r, \quad z \in \mathbb{D}\};$$

that is, the set

$$\{z : \tanh^{-1}(|z|) = r, \quad z \in \mathbb{D}\},$$

or

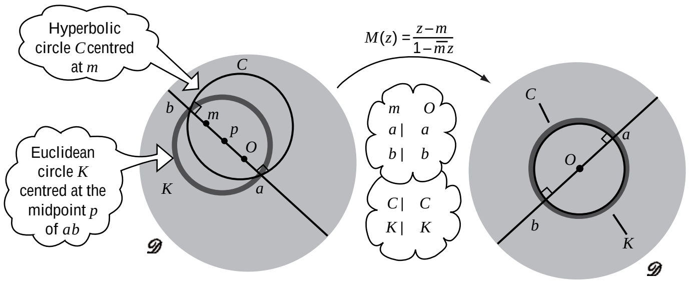
$$\{z : |z| = \tanh r, \quad z \in \mathbb{D}\}.$$

This is a Euclidean circle with radius $\tanh r$ centred at the origin! Even more remarkable is the fact that *every* hyperbolic circle is a Euclidean circle.

Theorem 1 Every hyperbolic circle is a Euclidean circle in $\mathbb{D}$, and vice versa.

Proof We have already established the result for circles centred at 0, so let C be any hyperbolic circle with hyperbolic centre $m \neq 0$. Let the diameter of $\mathbb{D}$ through m meet C at the points a and b, and let K be the Euclidean circle which has ab as a diameter and (Euclidean) centre p.

For the steps in the argument before Theorem 1 can be reversed.



We will show that C is a Euclidean circle by showing that it coincides with K. To do this let M be the hyperbolic transformation defined by

$$M(z) = \frac{z-m}{1-\overline{m}z}, \quad z \in \mathbb{D},$$

and let a' and b' be the images of a and b under M.

Since M preserves hyperbolic distances, and maps m to O, it must map C to a hyperbolic circle C' with centre O. But we already know that such a circle is also a Euclidean circle. Moreover, since the line segment ab passes through m, its image $a'b'$ passes through O and is therefore a diameter of C'.

Also, since M is angle-preserving, and since ab meets K at right angles, it follows that M maps K to a circle K' which meets $a'b'$ at right angles at the points a' and b'. This implies that $a'b'$ is also a diameter of K'. It follows that C' coincides with K', and hence that C coincides with K.

Theorem 2, Subsection 6.1.1

Conversely, let K be any Euclidean circle in $\mathbb{D}$ with Euclidean centre $p \neq 0$, and let the diameter of $\mathbb{D}$ through p meet K at the points a and b. If C is the hyperbolic circle through a and b with hyperbolic centre the hyperbolic midpoint m of ab, then we can use the same argument as before to deduce that K coincides with C, and so we conclude that K is a hyperbolic circle. ■

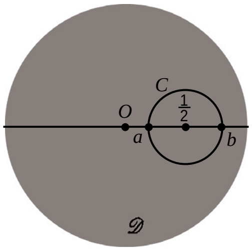
The above proof shows that the Euclidean and hyperbolic centres of a circle lie on the same line through O. This observation enables us to write down the following strategy for finding the Euclidean centre and radius of a hyperbolic circle.

Strategy To find the Euclidean centre and radius of a hyperbolic circle C with hyperbolic centre m:

1. find the points a, b where Om meets C;
2. the Euclidean centre of C is the Euclidean midpoint of ab;
3. the Euclidean radius of C is $\frac{1}{2}|a \quad b|$.

Example 4 Find the Euclidean centre and radius of the hyperbolic circle

$$C = \& \; z : d \quad z, \tfrac{1}{2} \quad = \tfrac{1}{2} \; ’ .$$



Solution Here the hyperbolic centre m is the point $\frac{1}{2}$, and so

$$d(0, m) = \tanh^{\;1} \; \tfrac{1}{2} \qquad 0.549.$$

Since the hyperbolic radius of C is equal to $\frac{1}{2}$, it follows that Om meets C at the points a, b, where

$$d(0, a) \quad 0.549 \quad 0.5 = 0.049,$$
$$d(0, b) \quad 0.549 + 0.5 = 1.049.$$

So

$$a \quad \tanh 0.049 \quad 0.049,$$
$$b \quad \tanh 1.049 \quad 0.782.$$

Since a and b both lie on the same side of 0, we have

$$\text{Euclidean centre} = \tfrac{1}{2}(a + b) \quad 0.415,$$
$$\text{Euclidean radius} = \tfrac{1}{2}|a \quad b| \quad 0.366.$$ □

Problem 4 Determine the Euclidean centre and radius of the hyperbolic circle

$$C = \& \; z : d \quad z, \quad \tfrac{1}{4} \quad = \tfrac{1}{2} \; ’ .$$

A similar strategy can be used to find the hyperbolic centre and radius of a Euclidean circle.

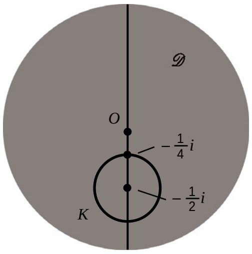
Strategy To find the hyperbolic centre and radius of a Euclidean circle K with Euclidean centre p:

1. find the points a, b where Op meets K;
2. the hyperbolic centre of K is the hyperbolic midpoint of ab;
3. the hyperbolic radius of K is $\frac{1}{2}d(a, b)$.

Example 5 Find the hyperbolic centre and radius of the Euclidean circle

$$K = \left\{ z : \left| z + \tfrac{1}{2} i \right| = \tfrac{1}{4} \right\}.$$

Solution Here the Euclidean centre p is the point $-\frac{1}{2}i$, and the Euclidean radius is $\frac{1}{4}$, so Op meets K at the points $a = -\frac{1}{4}i$ and $b = -\frac{3}{4}i$. Thus



$$d(0,a) = \tanh^{-1}\left|-\tfrac{1}{4}i\right| = \tanh^{-1}(0.25) \approx 0.255\ldots;$$

$$d(0,a) = \tanh^{-1}\left|-\tfrac{3}{4}i\right| = \tanh^{-1}(0.75) \approx 0.973\ldots.$$

Since a and b both lie on the same side of O, the hyperbolic centre m of K is given by

$$d(0,m) = \tfrac{1}{2}(d(0,a) + d(0,b)) \approx 0.614,$$

so that

$$\text{hyperbolic centre } m \approx -i \bullet \tanh 0.614 \approx -0.547i;$$

$$\text{hyperbolic radius} = \tfrac{1}{2}|d(0,a) - d(0,b)| \approx 0.359. \qquad \square$$

Problem 5 Determine the hyperbolic centre and radius of the Euclidean circle

$$K = \left\{ z : \left| z - \tfrac{1}{4} \right| = \tfrac{1}{2} \right\}.$$

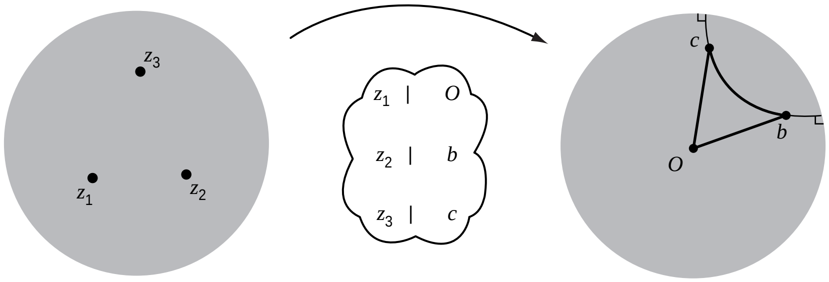
We now use the fact that hyperbolic circles are also Euclidean circles to prove the Triangle Inequality property of hyperbolic distance.

Property 3 of a distance function, Subsection 6.3.1.

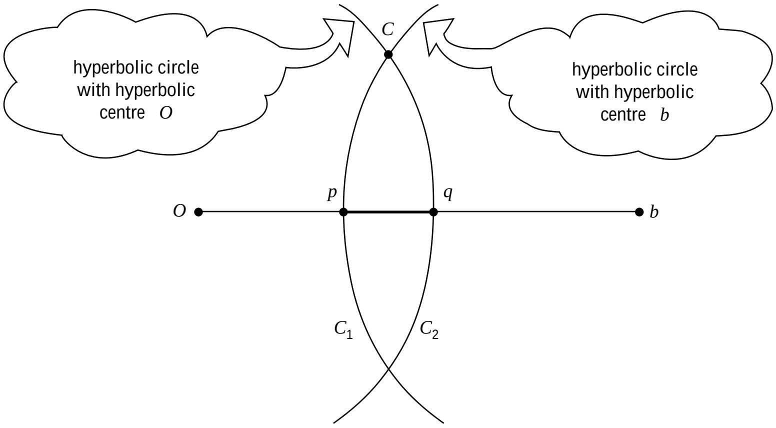
Theorem 2 For all z_1, z_2, z_3 in $\mathbb{D}$:

$$d(z_1,z_3) + d(z_3,z_2) \geq d(z_1,z_2).$$

Proof First let M be a hyperbolic transformation that maps z_1 to 0, and let $M(z_2) = b$ and $M(z_3) = c$. Then Ob is a straight line.



Taking O as centre we draw a hyperbolic circle C_2 through c to meet Ob at the point q; then $d(O,q) = d(O,c)$. Similarly, taking b as centre we draw a hyperbolic circle C_1 through c to meet Ob at the point p, where $d(b,p) = d(b,c)$.



hyperbolic circle with hyperbolic centre O
c
hyperbolic circle with hyperbolic centre b
p
q
O
b
C_1
C_2

We have drawn this figure in the case that p and q lie between O and b. The argument also holds if q lies beyond b or p beyond O.

Since both circles are also Euclidean circles with centres on Ob, and since the circles intersect, it follows that

$$\begin{aligned} d(0,c) + d(c,b) &= d(0,q) + d(p,b) \\ & \quad d(0,q) + d(q,b) \\ &= d(0,b). \end{aligned}$$

Recall that hyperbolic circles are Euclidean circles, by Theorem 1.

Since M preserves hyperbolic distances, we deduce that

$$d(z_1,z_3) + d(z_3,z_2) \quad d(z_1,z_2),$$

as required.

Property 6, Subsection 6.3.1

We can deduce from the Triangle Inequality (Property 3) that in hyperbolic geometry the curve of shortest length or geodesic between two points of $\mathbb{D}$ is the segment of the d-line that joins them. Rather loosely, we can express this fact as follows: Distances are measured along d-lines in hyperbolic geometry.

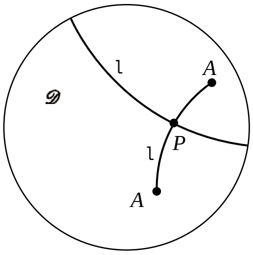
We omit a formal definition of length of a curve , and so a proof of this claim.

6.3.4 Reflected Points in Hyperbolic Geometry

In Euclidean geometry the image A of a point A under reflection in a line is an equal distance from the line and on the opposite side of the line, so that is the perpendicular bisector of the line segment AA. We now prove that the same result also holds in hyperbolic geometry, where the distances and lines are hyperbolic ones.

To state the result, we need the concept of *hyperbolic line segment*, or *d-line segment*; this is just that part of the d-line through two points which lies between those points.

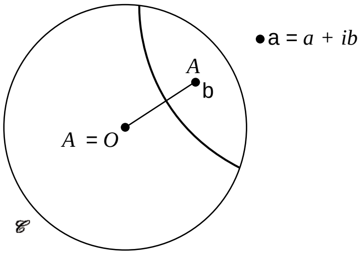
Theorem 3 Let A and A be points in the unit disc D that are images of each other under reflection in a d-line . Then is the hyperbolic perpendicular bisector of the hyperbolic line segment AA.



Proof Let the d-line through A and A meet at P.

Now A and A map to each other under hyperbolic reflection in , and P remains invariant. But hyperbolic reflection maps d-lines to d-lines, and there is exactly one d-line through A and A. Thus must map onto itself under the hyperbolic reflection in , and the hyperbolic line segment PA must map onto the hyperbolic line segment PA.

But hyperbolic reflection preserves angles and lengths. Since lengths are preserved, it follows that PA and PA must be of equal hyperbolic length. Also, since the angles that PA and PA make with the same part of at P map onto each other, they must be equal too; since they must add up to a total angle at P (because APA is a hyperbolic line segment through P), it follows that PA and PA both meet at right angles.



We already know one case where we can find the hyperbolic perpendicular bisector of a hyperbolic line segment AA. This is the case where one of the vertices, say A, coincides with O, the centre of the disc D. In that case, the reflection that sends A (represented by the complex number) to O is given by $M(z) = \frac{\text{ﬂ}z \;\; 1}{\text{ﬂ}z \;\; \text{ﬂ}}$, for some $= a + ib$, with $| \; | > 1$.

The equation of the d-line obtained from in which the reflection takes place is, as we saw earlier,

By Corollary 1, Subsection 6.1.1

$$x^2 + y^2 \quad 2ax \quad 2by + 1 = 0.$$

Since $M(\;) = 0$, it follows from the formula for M that $\text{ﬂ} \quad 1 = 0$.

More generally, suppose we want to find a hyperbolic reflection that exchanges the points p and q in D. Again, the hyperbolic reflection that does this must be of the form

$$M(z) = \frac{\text{ﬂ}z \quad 1}{\text{ﬂ}z \quad \text{ﬂ}}.$$

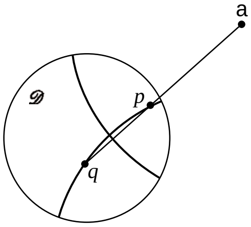
Subsection 6.2.1, Lemma 1

The condition $M(p) = q$ implies

$$q = \frac{\text{ﬂ}p \quad 1}{\text{ﬂ}p \quad \text{ﬂ}},$$

which is equivalent to

$$1 + \text{ﬂ}pq = \text{ﬂ}q + \quad \text{ﬂ}p. \tag{4}$$



The condition $M(q) = p$ implies

$$p = \frac{\text{ﬂ}q \quad 1}{\text{ﬂ}q \quad \text{ﬂ}},$$

which is equivalent to

$$1 + \text{ﬂ}qp = \text{ﬂ}p + \quad \text{ﬂ}q. \tag{5}$$

Equations (4) and (5) can be solved for provided that $p\bar{p} \quad q\bar{q} = 0$. Indeed, if we subtract q times equation (5) from p times equation (4), and then divide by $p\bar{p} \quad q\bar{q}$, we obtain

$$= \frac{p \quad q + pq(\bar{p} \quad \bar{q})}{p\bar{p} \quad q\bar{q}}.$$

Notice that in the special case when $q = 0$, this formula gives $= 1/\bar{p}$, as it should.

If $p\bar{p} \quad q\bar{q} = 0$, then $|p| = |q|$, in which case the sought-for reflection is simply Euclidean reflection in the diameter of D which bisects the angle pOq.

We summarize this discussion in the following lemma.

Lemma 1 Reflection Lemma

Let p and q be points in the unit disc D. If $|p| = |q|$, then the hyperbolic reflection that maps p and q onto each other is given by

$$M(z) = \frac{\bar{z} \quad 1}{z \quad \bar{}}, \quad \text{where} \quad = \frac{p \quad q + pq(\bar{p} \quad \bar{q})}{p\bar{p} \quad q\bar{q}}.$$

The d-line in which this reflection takes place has equation

$$x^2 + y^2 \quad 2ax \quad 2by + 1 = 0, \quad \text{where} \quad = a + ib.$$

By Lemma 1, Subsection 6.1.1

Example 6 Determine the equation of the hyperbolic perpendicular bisector of [0.2, 0.9], the line segment from 0.2 to 0.9.

Solution Using the Reflection Lemma, with $p = 0.9$ and $q = 0.2$, we find that

$$= \frac{0.7 + 0.9 \bullet 0.2 \bullet 0.7}{0.81 \quad 0.04} \quad 1.0727.$$

So the equation of the d-line which is the (hyperbolic) perpendicular bisector of [0.2, 0.9] is

$$x^2 + y^2 \quad 2ax + 1 = 0, \quad \text{where } a \quad 1.0727.$$ □

Problem 6

(a) Determine the equation of the hyperbolic perpendicular bisector of the line segment $[0.5, 0.8]$.

(b) Deduce the equations of the hyperbolic perpendicular bisectors of the line segments $[\quad 0.8, \quad 0.5]$ and $[0.5i, 0.8i]$.

We often write $[z_1, z_2]$ to mean the Euclidean line segment in C with endpoints z_1, z_2.

Problem 7

(a) Let A be a point in D, a d-line through A, and $0 < \quad < \quad$. Prove that there are exactly two d-lines through A that make an angle with .

(b) Prove that, if ABC is a d-triangle, then there is a unique d-line that bisects BAC, and that reflection in maps the d-lines containing BA and CA onto each other.

6.3.5 Proofs

In Subsection 6.3.1 we asserted that the hyperbolic distance between two points is invariant under hyperbolic transformations. We now supply a proof of this fact.

Theorem 4 The formula for hyperbolic distance

$$d(z_1, z_2) = \tanh^{1} \frac{z_2 \quad z_1}{1 \quad \bar{z}_1 z_2}, \quad \text{where } z_1, z_2 \quad \mathsf{D},$$

satisfies Property 6; that is,

$$d(z_1, z_2) = d(M(z_1), M(z_2))$$

for all z_1 and z_2 in D and all direct hyperbolic transformations M in G_{D}.

See Subsection 6.3.1.

Proof First, we define the expression $R(z_1, z_2)$ to be

$$R(z_1, z_2) = \frac{z_2 \quad z_1}{1 \quad \bar{z}_1 z_2}, \quad \text{where } z_1, z_2 \quad \mathsf{D}. \tag{6}$$

It follows from the definition of $d(z_1, z_2)$ above that

$$d(z_1, z_2) = \tanh^{1}(R(z_1, z_2));$$

We omit the details of this, for brevity.

hence d possesses Property 6 if we can prove that

$$R(z_1, z_2) = R(M(z_1), M(z_2)) \tag{7}$$

for all $z_1, z_2 \quad \mathsf{D}$ and all $M \quad G_{\mathsf{D}}$.

So, let $z_1, z_2 \quad \mathsf{D}$ and $M \quad G_{\mathsf{D}}$. Then the direct hyperbolic transformation M_1 in G_{D} given by

$$M_1 : z \quad \frac{z \quad z_1}{1 \quad \overline{z_1} z}, \quad z \quad \mathsf{D},$$

maps z_1 to 0, and z_2 to $\frac{z_2 \quad z_1}{1 \quad \bar{z}_1 z_2}$.

Also, the direct hyperbolic transformation M_2 in G_{D} given by

$$M_2 : z \quad \frac{z \quad M(z_1)}{1 \quad \overline{M(z_1)} z}, \quad z \quad \mathsf{D},$$

where $M \quad G_{\mathsf{D}}$ so that $|M(z_1)| < 1$, maps $M(z_1)$ to 0, and $M(z_2)$ to $\frac{M(z_2) \quad M(z_1)}{1 \quad \overline{M(z_1)} M(z_2)}$.

Now, the composite mapping $M_2 \circ M \circ M_1^{-1}$ is also a transformation in $G_{\mathbb{D}}$. It maps $\mathbb{D}$ to $\mathbb{D}$, 0 to 0, and

$$\frac{z_2 - z_1}{1 - \overline{z}_1 z_2} \quad \text{to} \quad \frac{M(z_2) - M(z_1)}{1 - \overline{M(z_1)}M(z_2)}. \tag{8}$$

Note that M_1^{-1} maps 0 to z_1, and $\frac{z_2 - z_1}{1 - \overline{z}_1 z_2}$ to z_2.

But any direct transformation in $G_{\mathbb{D}}$ that maps 0 to 0 is simply a (Euclidean) rotation; so it follows from equation (8) that

$$\left|\frac{z_2 - z_1}{1 - \overline{z}_1 z_2}\right| = \left|\frac{M(z_2) - M(z_1)}{1 - \overline{M(z_1)}M(z_2)}\right|. \tag{9}$$

See Case 1 of Theorem 2, Subsection 6.2.1.

It follows from the definition of R that we can rewrite equation (9) in the desired form

$$R(z_1, z_2) = R(M(z_1), M(z_2)).$$

We defined R in equation (6).

Next, we stated earlier that the function d that we used to define the hyperbolic distance function in $\mathbb{D}$ was *essentially* the only *well-behaved* function with Properties 1-6 of Subsection 6.3.1. We now explain why this is so.

Theorem 5 Let $d(z_1, z_2)$ be any *well-behaved* function defined for all $z_1, z_2 \in \mathbb{D}$ that satisfies Properties 1-6 of Subsection 6.3.1. Then

$$d(z_1, z_2) = K \tanh^{-1}\left(\left|\frac{z_2 - z_1}{1 - \overline{z_1} z_2}\right|\right), \text{ for some } K > 0. \tag{10}$$

Proof Let $z_1, z_2 \in \mathbb{D}$. Since hyperbolic distances are invariant under Möbius transformations, $d(z_1, z_2)$ is unchanged if we map z_1 to the origin by the direct hyperbolic transformation (a Möbius transformation)

$$z \mapsto \frac{z - z_1}{1 - \overline{z_1} z}.$$

By Property 6

Next, hyperbolic distances are invariant under rotations of $\mathbb{D}$, since such rotations are hyperbolic transformations. So, we may also assume that z_2 lies on the positive real axis.

Hence, in order to prove the formula (10) it is sufficient to prove that

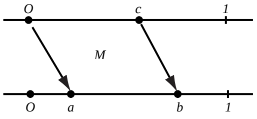
$$d(0, z) = K \tanh^{-1}(z), \text{ for some } K > 0 \text{ and all } z \in (0, 1). \tag{11}$$

For simplicity, we will now simply write $d(z)$ in place of $d(0, z)$ whenever the context means that no confusion will arise.

Let $0 < a, c < 1$. Then the direct hyperbolic transformation (a Möbius transformation)

$$M(z) = \frac{z + a}{1 + az}, \quad z \in \mathbb{D}$$

maps 0 to a, and c onto $b = \frac{c+a}{1+ac}$. Since M maps $[0, 1)$ one-one to $[a, 1)$, we must have $a < b < 1$.



Now, hyperbolic distances are additive along a line, so that

$$d(b) = d(a) + d(a, b). \tag{12}$$

By Property 4

But, since hyperbolic distances are invariant under hyperbolic transformations, we have

By Property 6

$$\begin{aligned} d(a,b) &= d(0,c) \\ &= d(c), \end{aligned}$$

so that it follows from equation (12) that

In this equation, a and c are independent variables.

$$d\left(\frac{c+a}{1+ac}\right) = d(a) + d(c). \qquad (13)$$

Now we will assume that the function d is differentiable on $[0,1)$. If we then differentiate both sides of equation (13) with respect to the variable c, we get

This is where we use the hypothesis that the distance function is well-behaved.

$$d'\left(\frac{c+a}{1+ac}\right) \cdot \frac{(1+ac)\cdot 1 - (c+a)\cdot a}{(1+ac)^2} = 0 + d'(c);$$

and we may rewrite this equation in the form

$$d'\left(\frac{c+a}{1+ac}\right) = \frac{(1+ac)^2}{1-a^2} \cdot d'(c).$$

If we substitute 0 for c into this equation, we get

Here $d_R'(0)$ is the right derivative of d at 0.

$$\begin{aligned} d'(a) &= \frac{d_R'(0)}{1-a^2} \\ &= \frac{K}{1-a^2}, \text{ for some real } K. \end{aligned}$$

Since d must be an increasing function on $[0,1)$, we must have $K \geq 0$. But we cannot have $K = 0$, as it would then follow from the above equation that $d'(a) = 0$ for all $a \in [0,1)$ - so that $d(0,a)$ takes the same value (which would have to be 0) for all $a \in [0,1)$. Hence

This follows from Property 1.

$$d'(a) = \frac{K}{1-a^2}, \text{ for some } K > 0, \text{ and all } a \in (0,1).$$

If we then integrate both sides of this formula from 0 to z, we get

$$d(z) = K\tanh^{-1}(z), \text{ for some } K > 0, \text{ and all } z \in [0,1).$$

Remarks

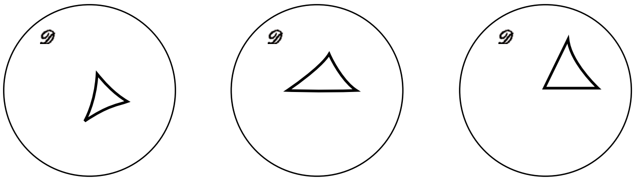
1. For any (complex) point z near the origin, equation (10) gives
$$\begin{aligned} d(0,z) &= K\tanh^{-1}(|z|) \\ &\simeq K|z|, \end{aligned}$$
so it is natural to make the choice $K = 1$ for the definition of distance in hyperbolic geometry. Then $d(0,z) = \tanh^{-1}(|z|)$, for all $z \in \mathbb{D}$.
2. When $d(0,z) = \tanh^{-1}(|z|)$, $z \in \mathbb{D}$, we can reformulate the equation $d'(z) = \frac{1}{1-|z|^2}$ in the form
$$\mathrm{d}s = \frac{|\mathrm{d}z|}{1-|z|^2},$$
relating infinitesimal hyperbolic distances ds to infinitesimal Euclidean distances $|\mathrm{d}z|$ in $\mathbb{D}$ near any point $z \in \mathbb{D}$.

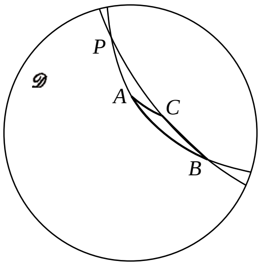
In advanced texts, the formula for hyperbolic distance is often used in this infinitesimal form.

6.4 Geometrical Theorems

6.4.1 Triangles

A **triangle** in hyperbolic geometry, or a ***d*-triangle,** consists of three points in the unit disc D that do not lie on a single *d*-line, together with the segments of the three *d*-lines joining them. One or two of the sides may be segments of diameters of D; but, in general, the sides are parts of Euclidean circles.





Notice that if ABC is a *d*-triangle, then the extended sides can meet only at A, B and C. For if the *d*-lines through *A* and *B* and through *B* and C meet at a point *P* distinct from *B*, then the two *d*-lines meet at *B* and *P*. But we saw earlier that there is a unique *d*-line through any two points of D; so it would follow that *AB* and *BC* are part of a single *d*-line, a possibility that we have already excluded. So the sides of a *d*-triangle cannot overlap .

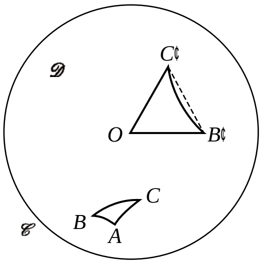
Subsection 6.1.2,
Theorem 4

One of the basic results in Euclidean geometry is that the sum of the angles of a (Euclidean) triangle is . This is *not* true for *d*-triangles in hyperbolic geometry!

Theorem 1 The sum of the angles of a *d*-triangle is less than .

Proof By the Origin Lemma, we can map the *d*-triangle ABC onto a *d*-triangle OB C by any hyperbolic transformation that sends *A* to the origin *O*. Since hyperbolic transformations preserve angles, the sums of the angles of the two *d*-triangles are the same.

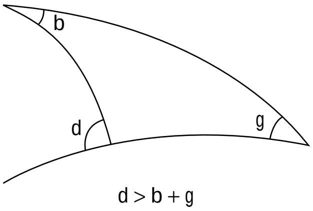
Subsection 6.1.2,
Lemma 2

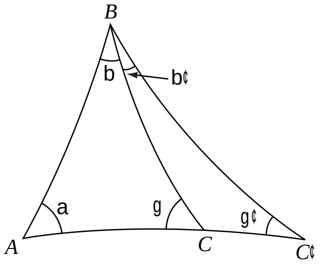


Then *OB* and *OC* are parts of Euclidean lines, and *B C* is part of a Euclidean circle that bends towards the origin. Thus the angles at *B* and *C* of the *d*-triangle OB C are less than the corresponding angles of the Euclidean triangle OB C , and the angles of both triangles at *O* are the same.

Since the sum of the angles of the Euclidean triangle OB C is , it follows that the sum of the angles of the *d*-triangle OB C is (strictly) less than . The result then follows.

Problem 1 Prove that each external angle of a *d*-triangle is greater than the sum of the opposite two internal angles. (See the diagram on the left below.)



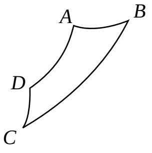


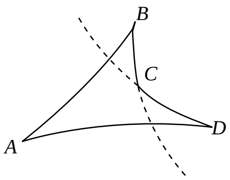
Problem 2 Let ABC and ABC be two hyperbolic triangles such that A, C and C lie on a d-line in this order. Let the angles at A, B, C in the first triangle and at A, B, C in the second triangle be , , and , + , , respectively. Show that + + > + + + . (See the diagram on the right, above.)

It will be seen from Problem 2 that the larger triangle, ABC, has the smaller angle sum. This is true in general, not only when one triangle fits neatly inside another. In fact, it can be shown that the area of a hyperbolic triangle with angles , and is proportional to (+ +), and we shall prove this in Subsection 6.5.1. You may for the moment use the following result as a useful memory aid:

> small triangles have angle sums close to (but less than) , and triangles with large areas have angle sums close to zero.

In Euclidean geometry, we can also prove that the sum of the angles of a (Euclidean) quadrilateral equals 2 . Now, a **quadrilateral** $ABCD$ in hyperbolic geometry, or a ***d*-quadrilateral,** consists of four points A, B, C, D in D (no three of which lie on a single d-line), together with the segments AB, BC, CD and DA of the four d-lines joining them. We require also that no two of these segments meet except at one of the points A, B, C or D.



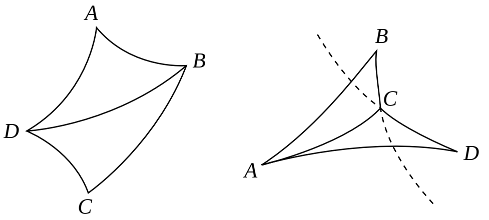


How large can the sum of the angles of a d-quadrilateral be?

Theorem 2 The sum of the angles of a d-quadrilateral is less than 2 .

Proof Any d-quadrilateral can be divided into two (non-overlapping) d-triangles by one or other of the d-lines joining alternate vertices.

We shall assume this fact without proof; see the figures below.



The angles of each d-triangle sum to less than π. The angles of the d-quadrilateral belong to one or other d-triangle, or partly to one and partly to the other. It follows that the angles of the d-quadrilateral sum to less than 2π.

We shall use this fact later.

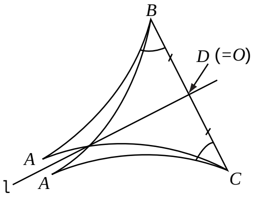
In hyperbolic geometry there are many theorems about d-triangles that are analogues of the corresponding theorems about Euclidean triangles, such as the following.

Theorem 3 Let $\triangle ABC$ be a d-triangle in which $\angle ABC = \angle ACB$. Then the sides AB and AC are of equal length.

This is the hyperbolic analogue of the Euclidean result in Example 1, Subsection 2.1.1.

Proof Let D be the midpoint of the d-line segment BC. By applying the Origin Lemma, if necessary, we may assume that D coincides with O, the centre of the disc $\mathbb{D}$. (Although this is not strictly necessary for the proof, it simplifies the picture.) Then BC is part of a diameter of $\mathbb{D}$.

Let the d-line ℓ be the perpendicular bisector of BC; it is the diameter of $\mathbb{D}$ perpendicular to BC. Reflect (in both the Euclidean and hyperbolic senses) the triangle $\triangle ABC$ in the d-line ℓ. Because reflections preserve length, and $DB = DC$, it follows that B and C change places. Suppose that A moves to some point A'. Since reflection preserves angles, it follows that $\angle A'BC = \angle ACB$. Also, recall that we are given that $\angle ACB = \angle ABC$, so $\angle A'BC = \angle ABC$. But this can happen only if A' lies on the d-line through A and B. Similarly, $\angle A'CB = \angle ABC = \angle ACB$, so A' must also lie on the d-line through A and C. This means that A and A' must coincide. Hence the d-line segment BA reflects to the d-line segment CA, and vice versa; so these d-line segments have the same length.



Problem 3 Let $\triangle ABC$ be a d-triangle in which the sides AB and AC have equal hyperbolic length. Prove that $\angle ABC = \angle ACB$.
Hint: Consider reflection in the d-line that bisects angle $\angle BAC$.

The notion of mapping one figure onto another *exactly* by a transformation in the geometry (for example, the reflection in the d-line ℓ in the proof of Theorem 3) is one that we met previously: namely, congruence.

Definition Two figures in the unit disc $\mathbb{D}$ are ***d*-congruent** if there is a hyperbolic transformation that maps one onto the other.

For example, if A, B, C and D are four points in $\mathbb{D}$ such that the hyperbolic distances $d(A, B)$ and $d(C, D)$ are equal, then the d-line segment AB is congruent to the d-line segment CD. For, as we saw earlier, there is a hyperbolic transformation t that maps A to C and the d-line through A and B onto the d-line through C and D, in such a way that D and $t(B)$ lie on the same side of C along $t(\ )$. Then, since B and D are the same hyperbolic distances from A and C, respectively, it follows that t must map B onto D. Thus AB and CD are congruent.

Subsection 6.1.2, Theorem 5, and the Remark following that theorem.

Now, since hyperbolic transformations preserve angles, it follows that if two d-triangles do not have corresponding angles equal (that is, they are not **similar),** then they certainly cannot be d-congruent.

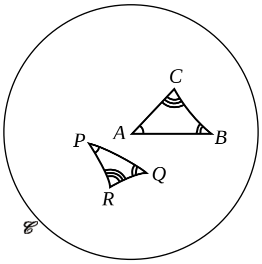
Recall that two Euclidean figures are *similar* if one is a scale copy of the other; in particular, two Euclidean triangles are similar if they have corresponding angles equal.

However, the following result is still very surprising, because the analogous result is *false* in Euclidean geometry.

Theorem 4 Similar d-triangles are d-congruent.

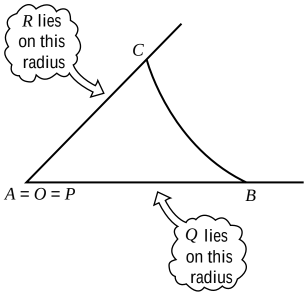
Proof We have to prove that if the d-triangles ABC and PQR have the angles at A, B and C and the angles at P, Q and R equal, respectively, then the two d-triangles are d-congruent.

We may apply a hyperbolic transformation to map A to the origin O; this does not change the angles of the triangle. To avoid complicated notation, we shall still denote this image d-triangle by ABC.



We can also apply a hyperbolic transformation to map P to the origin and the radius on which Q lies to the radius on which B lies. By reflecting in the d-line through O and B, if necessary, we can deduce from the fact that the angles at A and P are equal that the image of R lies on the same radius as (the image of) C. Again, we shall denote the image d-triangle still by the notation PQR, for simplicity.

The following figure shows the result of the transformations described above.



To prove the result, we have to show (in terms of the points obtained by the above preliminary mappings) that $B = Q$ and $C = R$. We proceed by considering the various possible situations that would arise if the result were false.

(a) *The d-line segment BC might lie between the origin and the d-line segment QR.* (The argument is similar if QR lies between O and BC.)

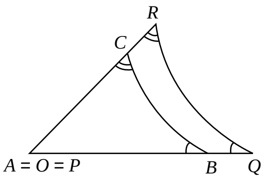
In this case,

$$RCB = OCB \quad \text{and} \quad CBQ = OBC,$$

so the angle sum of the d-quadrilateral $CBQR$ is

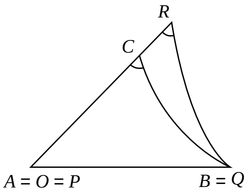
$$(\quad OCB) + (\quad OBC) + OQR + ORQ = 2\ ,$$

which is impossible, by Theorem 2.



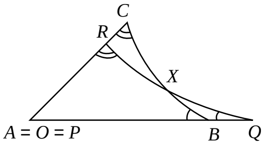
(b) *B and Q may coincide, but not C and R.* (The argument is similar if R lies between O and C, or if C and R coincide, but not B and Q.)

In this case, if C lies between O and R, the external angle at C of the d-triangle BCR is less than or equal to the sum of the opposite two internal angles, which is impossible by the result of Problem 1.



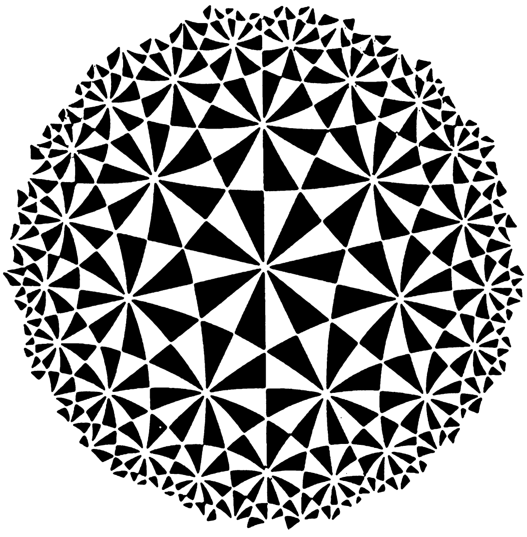
(c) *The d-line segments BC and QR may cross*.

Let the point of intersection of BC and QR be X. In this case, the external angle at B of the d-triangle XBQ is less than or equal to the sum of the opposite two internal angles, which is impossible by the result of Problem 1.



It follows that the only possibility is that $B = Q$ and $C = R$, as required.

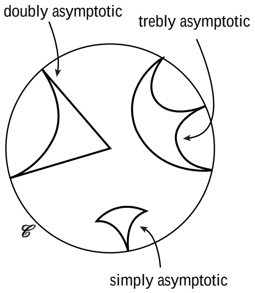
In the following diagram, all the d-triangles have the same angles at their vertices, and so are similar. It follows from Theorem 4 that they are d-congruent to each other.



This looks very unlikely, since the triangles *seem* to be getting smaller as they move away from the origin towards C; however, it is a consequence of the way in which we defined both hyperbolic transformations and hyperbolic distance that all the triangles have sides of the same (hyperbolic) lengths as well as angles of the same sizes. This results from the fact that equal Euclidean distances on a ruler correspond to increasing hyperbolic distances as the ruler is moved outwards.

Asymptotic Triangles

The vertices of d-triangles lie in the unit disc D. However, it is often useful to talk about figures in D with three sides that are d-lines but where one or more of the Euclidean circles or lines of which they are part meet on C rather than in D. In this sense, we say that they are triangles with one or more vertices on C ; such triangles are called **asymptotic triangles**.



If an asymptotic triangle has one vertex on C is said to be **simply asymptotic**, if it has two vertices on C **doubly asymptotic**, and three vertices on C **trebly asymptotic**.

There is no hyperbolic transformation that maps points of C to points of D, or vice-versa; so asymptotic triangles are *essentially* different from ordinary d-triangles. However, it turns out that many of the results that hold for d-triangles hold also for asymptotic triangles, and that their proofs are similar.

Theorem 5 The angle sum of an asymptotic triangle is less than . The angle sum of a trebly asymptotic triangle is zero.

We omit the proof of this result. The proof of the first assertion is similar to that of Theorem 1.

Problem 4 Prove that two doubly asymptotic triangles are d-congruent if and only if they have the same angle at their vertex in D.

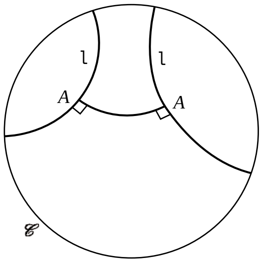
In hyperbolic geometry you should be careful not to assume that results are valid simply because they hold in Euclidean geometry. Sometimes asymptotic triangles are useful in constructing counter-examples.

We shall do exactly this at the end of Subsection 6.4.2.

6.4.2 Perpendicular Lines

In Euclidean geometry, two given lines and have a common perpendicular if and only if they are parallel to each other. In hyperbolic geometry, the situation is somewhat different, as you will see. First, we must define the term *common perpendicular* in hyperbolic geometry.

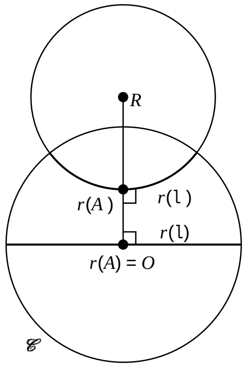
Definition Let and be two d-lines, and suppose that there exist points A on and A on such that the d-line segment AA meets and at right angles. Then AA is a **common perpendicular** to and .

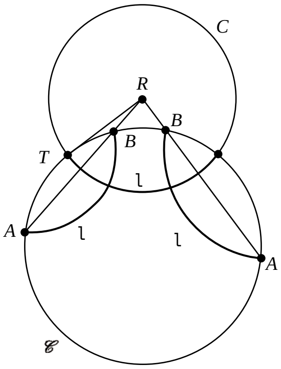


Theorem 6 Common Perpendiculars Theorem
Two d-lines have a common perpendicular if and only they are ultra-parallel. This common perpendicular is unique.

Proof First we show that if two d-lines and have a common perpendicular, then they are ultra-parallel. Let the common perpendicular be the d-line segment AA, where A is on and A is on . By the Origin Lemma, we can find a transformation r G_{D} which maps the point A to the origin, O. Then the d-line $r(\ )$ is a diameter of the disc D, as shown on the left below. The

d-line $r(\;)$ is part of a Euclidean circle whose centre R lies somewhere outside the disc D on the continuation of the diameter joining O to $r(A\;)$. The radius of this Euclidean circle is less than RO, and RO is perpendicular to $r(\;)$, so this circle cannot meet $r(\;)$, and hence $r(\;)$ and $r(\;)$ are ultra-parallel. It follows that the d-lines and are ultra-parallel.



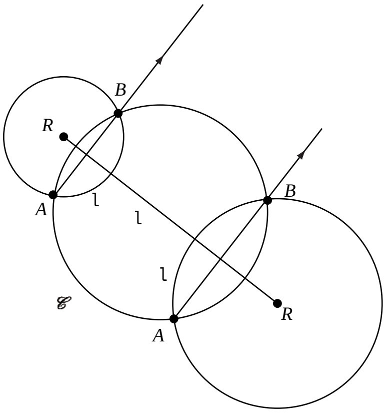


Secondly, we show that if two d-lines and are ultra-parallel, then they have a common perpendicular. As shown in the figure on the right above, let the boundary points of be A and B, and the boundary points of be A and B. Consider the *Euclidean* lines AB and $A\ B$.

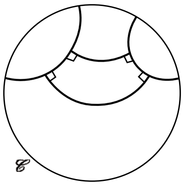
If the Euclidean lines AB and $A\ B$ are not parallel, then they meet at a point R outside D, as shown on the right above. Let RT be a tangent from R to the boundary circle C. Consider the circle C with centre R and radius RT. This circle meets C at right angles, so the part of it in D is a d-line, say.

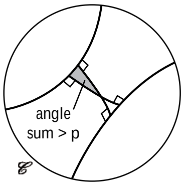
The Euclidean triangles RTB and RAT are similar, since $TRB = ART$ (being the same angle) and $RTB = RAT$ (since the exterior angle equals the interior opposite angle for a tangent and chord of a circle). Hence, in particular, $RB/RT = RT/RA$ so that $RA \bullet RB = RT^2$. In other words, A and B are inverse points with respect to the circle with centre R and radius RT.

Inversion in C exchanges A and B, and exchanges A and B. So it maps the d-line to itself, and the d-line to itself. It follows that intersects and at right angles, and so a common perpendicular to the d-lines and exists.



If the Euclidean lines *AB* and *A B* are parallel, then there is a diameter of D that is the perpendicular bisector of *AB* and *A B* . It therefore passes through the centres *R* and *R* of the Euclidean circles of which and are parts, and so it is perpendicular to both and . Since is a diameter of D it is a *d*-line, and the common perpendicular we seek exists.





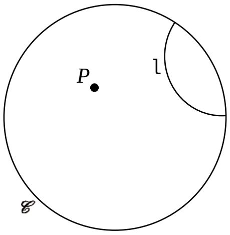
Finally, the common perpendicular to two ultra-parallel lines is unique. For, if there were two, and they were disjoint (as shown on the top illustration alongside), they and the two ultra-parallel lines would form four sides of a hyperbolic quadrilateral all of whose angles were right angles. But then the angle sum of such a quadrilateral would be 2 , which is impossible. Similarly, if there were two common perpendiculars that intersected each other (as shown in the lower illustration alongside), we should have a *d*-triangle whose angle sum was , which is impossible.

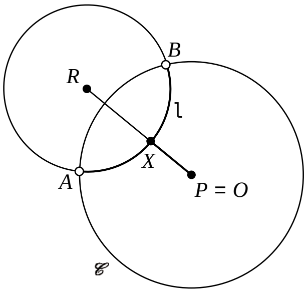
It follows that the common perpendicular to two ultra-parallel lines is unique.

In Euclidean geometry, the altitudes of a triangle play an interesting role; this is also the case in hyperbolic geometry.

Before we can talk about altitudes, we need to prove that through any point *P* not on a given *d*-line there is necessarily another (unique) *d*-line *p* such that *p* meets at right angles.

This fact is needed in order to prove that altitudes of a given *d*-triangle *exist*.



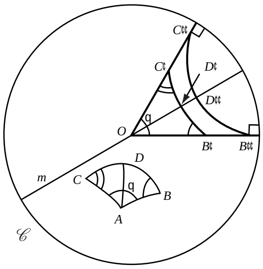


By a preliminary hyperbolic transformation, if necessary, we may assume that *P* is the origin. Let have boundary points *A* and *B*, and let *R* be the centre of the Euclidean circle of which is a part. Let the (Euclidean) line *OR* meet at X; *OR* and intersect at right angles at X, so that the d-line segment *OX* is a perpendicular from O to . The diameter which includes *OX* meets at right angles, as required. It is unique because no other line through O can meet at right angles.

Thus it is possible to drop a perpendicular from a point to a d-line, and so it makes sense to talk about *the* altitude through a vertex of a d-triangle.

Definition Let be a d-line which passes through one vertex A of a d-triangle *ABC* and which is perpendicular to the side *BC* at the point D. The d-line segment *AD* is an **altitude** of the triangle *ABC*.

Theorem 7 Altitude Theorem
Let the sides *AB* and *AC* of a d-triangle *ABC* be of equal hyperbolic length, and let the angle at A be . Then the hyperbolic length of the altitude through A of the triangle is less than some number that depends only on .



Proof Map the d-triangle *ABC* onto a d-triangle *OB C* by any hyperbolic transformation that sends A to the origin O. Since hyperbolic transformations preserve (hyperbolic) lengths and angles, *OB* and *OC* are of equal length and *B OC* = .

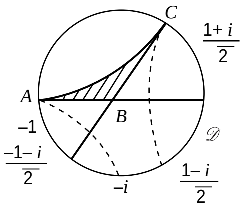
Let the diameter m of D that bisects the angle *B OC* meet the d-line segment *B C* at D. It is clear, by symmetry, that the d-line segment *OD* must be perpendicular to the d-line segment *B C*, so that *OD* (which is part of a Euclidean line) is the altitude of the d-triangle *OB C* through O. Since d-triangles have a unique altitude through each vertex, the altitude *AD* of the d-triangle *ABC* must map onto the altitude *OD*, and so they are of equal hyperbolic length.

Then the length of *OD* is less than the length of *OD*, where D lies on m and the d-line joining the boundary points B and C of the lines *OB* and *OC* (as shown). It follows that the hyperbolic length of the original altitude *AD* is less than the hyperbolic length of *OD*, which clearly depends only on .

Problem 5 Prove that the d-triangles *OB D* and *OC D* in the proof of Theorem 7 are d-congruent.

Problem 6 Determine a (numerical) upper bound for the hyperbolic length of the altitude *AD* of an isosceles d-triangle *ABC* in which *AB* and *AC* are of equal hyperbolic length and the angle at A is a right angle. *Hint:* This situation is a special case of that in Theorem 7: = /2, so B and C in the proof of that theorem are 1 and i, respectively.

In Euclidean geometry the altitudes of a triangle are concurrent; but this is not true in general in hyperbolic geometry. For example, let A, B and C be the points 1, 0 and $\frac{1+i}{2}$. Then the altitudes through A and C of the d-triangle ABC are the d-lines with endpoints 1, i and $\frac{1+i}{2}$, $\frac{1\ \ i}{2}$, respectively. These d-lines do not meet anywhere in D or on C. So certainly the altitudes of a doubly asymptotic triangle are not concurrent.



Finally, if we choose a (non-asymptotic) d-triangle with one vertex at O and the other two vertices in D but very close to A and C, it is clear that the altitudes of *this* d-triangle cannot be concurrent.

6.4.3 Right-Angled *d*-Triangles

In Euclidean geometry, Pythagoras Theorem plays a central role in many calculations. As we have seen, however, the theorem does not hold in hyperbolic geometry if we simply replace Euclidean lines by d-lines and Euclidean distances by hyperbolic distances in its statement.

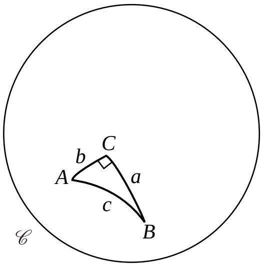
Paragraph following Example 2 of Subsection 6.3.1.

However it seems reasonable to imagine that hyperbolic functions might play some role in a version of Pythagoras Theorem in hyperbolic geometry, and indeed this is the case.

Theorem 8 Pythagoras' Theorem
Let ABC be a d-triangle in which the angle at C is a right angle. If a, b and c are the hyperbolic lengths of BC, CA and AB, then

$$\cosh 2c = \cosh 2a \times \cosh 2b.$$

We prove Theorem 8 later in this subsection.



Problem 7 Use Pythagoras Theorem to determine the hyperbolic lengths of the sides of the d-triangle with vertices $0, (1+i)/2\ \ 2$ and $(\ \ 1+i)/5\ \ 2$, which has a right angle at O.

Problem 8 Use Pythagoras Theorem to determine the hyperbolic lengths of the sides of the d-triangles with vertices at the following points:

(a) $0, \frac{3}{4}$ and $\frac{3}{4}i$; (b) $0, r$ and ir (where $0 < r < 1$).

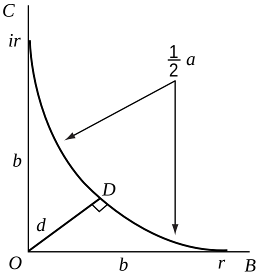
We can use these ideas to provide another solution to Problem 6 above.

Example 1 Prove that, if ABC is an isosceles d-triangle in which AB and AC are of equal hyperbolic lengths and the angle at A is a right angle, then the hyperbolic length of the altitude AD is less than $\frac{1}{2}\cosh^{1}\ \ 2\ \ \ 0.4407$ which is $\frac{1}{2}\log_e\ \ 1+\ \ 2$.

In Problem 6 we found that this upper bound $\frac{1}{2}\cosh^{1}\ \ 2$ was equal to $\tanh^{1}\ \ 2\ \ 1$; in fact the two numbers are equal. Such unexpected identities involving hyperbolic functions occur surprisingly often!

Solution The given triangle is d-congruent to the d-triangle OBC with vertices at $0, r$ and ir, for some r with $0 < r < 1$. Let OD be an altitude of this triangle. Let the hyperbolic lengths of the sides OB and OC be denoted by b, of side BC by a, and of the altitude OD by d.

It follows from Problem 5 (or by symmetry) that D is the Euclidean midpoint and the hyperbolic midpoint of the d-line segment BC, so that the d-line segments BD and CD both have hyperbolic length $\frac{1}{2}a$.



By applying Pythagoras' Theorem to the d-triangle $\triangle OBD$, we find that

$$\begin{aligned}\cosh 2b &= (\cosh 2d) \times \cosh 2\left(\tfrac{1}{2}a\right)\\ &= (\cosh 2d) \times \cosh a. \qquad (1)\end{aligned}$$

Next, by applying Pythagoras' Theorem to the d-triangle $\triangle OBC$, we find that

$$\cosh 2a = \cosh^2 2b. \qquad (2)$$

Now, we may rewrite equation (2) in the form

$$2\cosh^2 a - 1 = \cosh^2 2b; \qquad (3)$$

Here we use the identity $\cosh^2 2x = 2\cosh^2 x - 1$, for $x \in \mathbb{R}$.

and if we then substitute for $\cosh a$ from equation (1) into equation (3), we obtain

$$2\left(\frac{\cosh 2b}{\cosh 2d}\right)^2 - 1 = \cosh^2 2b.$$

We may rearrange this equation in the form

$$\left(\frac{\cosh 2d}{\cosh 2b}\right)^2 = \frac{2}{1 + \cosh^2 2b},$$

so that

$$\begin{aligned}\cosh 2d &= \frac{\sqrt{2}\cosh 2b}{\sqrt{(1 + \cosh^2 2b)}}\\ &= \frac{\sqrt{2}}{\sqrt{1 + \frac{1}{\cosh^2 2b}}}\\ &< \sqrt{2}.\end{aligned}$$

It follows that $d < \frac{1}{2}\cosh^{-1}\left(\sqrt{2}\right) \simeq 0.4407$, as claimed. □

Pythagoras' Theorem takes a simple, if unexpected, form in hyperbolic geometry. Moreover, the relationship closely approximates the Euclidean one if the sides of the triangle are very small, which is what you would expect because small hyperbolic triangles have angle sums nearly equal to π and so are nearly Euclidean themselves. To see the relationship, we expand the cosh terms as power series, using the formula

$$\cosh 2c = 1 + \frac{(2c)^2}{2!} + \text{ higher powers of } 2c.$$

If we ignore the higher powers of $2c$, as we may when $2c$ is very small, we find

$$\cosh 2c \simeq 1 + 2c^2$$

Recall that

$$\begin{aligned}\cosh x &= 1 + \frac{x^2}{2!} + \frac{x^4}{4!} + \ldots\\ &= \sum_{n=0}^{\infty} \frac{x^{2n}}{(2n)!}\end{aligned}$$

for all $x \in \mathbb{R}$.

and

$$\cosh 2a \times \cosh 2b \qquad 1 + 2a^2 \quad 1 + 2b^2$$

$$= 1 + 2a^2 + 2b^2 + 4a^2b^2.$$

If we ignore the term $4a^2b^2$ on the grounds that it is as small as other terms we have already dropped, then we are left with

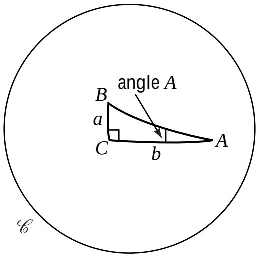
$$1 + 2c^2 \quad 1 + 2a^2 + 2b^2,$$

which reduces to

$$c^2 \quad a^2 + b^2.$$

So for small d-triangles the hyperbolic version of Pythagoras Theorem is essentially the same as the Euclidean version.

In Euclidean geometry there is a simple connection between the lengths of the sides of a right-angled triangle and its angles. An analogous result exists in hyperbolic geometry also.



Theorem 9 Lobachevskii’s Formula
Let the d-triangle ABC have a right angle at C, and let the hyperbolic lengths of sides AC and BC be b and a, respectively. Then

$$\tan A = \frac{\tanh 2a}{\sinh 2b}.$$

We prove this result later in the subsection.

For example, let the points A, B, C be $\frac{1}{2}, \frac{1}{2}i$ and 0, respectively. Then it follows from Lobachevskii s Formula that

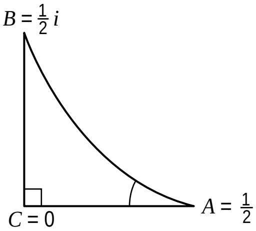
$$\tan A = \frac{\tanh 2d \quad 0, \frac{1}{2}i}{\sinh 2d \quad 0, \frac{1}{2}}$$

$$= \frac{\tanh 2d \quad 0, \frac{1}{2}}{\sinh 2d \quad 0, \frac{1}{2}}$$

$$= \frac{1}{\cosh 2d \quad 0, \frac{1}{2}}$$

$$\frac{1}{1.6667} \qquad 0.6,$$

so that $A \quad \tan^{\ 1} 0.6 \quad 0.5404$ radians.



Remark

It can be shown that when the triangle is very small, and so nearly Euclidean, $\tanh 2a$ is approximately $2a$ and $\sinh 2b$ is approximately $2b$, so that $\tan A \quad a/b$, which is the Euclidean value.

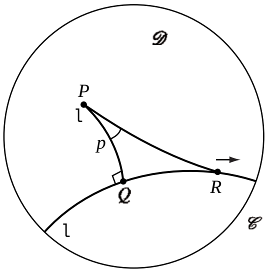
Problem 9 Determine the angle at A in the d-triangle ABC with vertices $\frac{3}{5}i$, $\frac{4}{5}$ and 0, respectively.

We can also use these ideas to answer another question that loomed very large in the discovery of hyperbolic geometry.

Let be the d-line from a point P that is perpendicular to a d-line not through P, and let p be the length of the segment of from P to . What is the angle between and a d-line through P which is parallel to ?

The angle is called the angle of parallelism .

Let Q be the foot of the perpendicular from P to , and R a point on different from Q. As the point R moves away from Q towards C, the hyperbolic length of QR, $d(Q, R)$, tends to infinity; it follows that tanh $2d(Q, R)$ tends to 1 as R approaches C.



From Lobachevskii s Formula,

$$\tan \quad QPR = \frac{\tanh 2d(Q, R)}{\sinh 2p},$$

and so, if we let R approach C along , it follows that

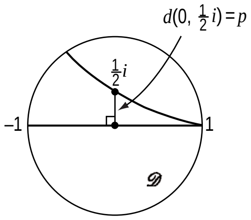
$$\tan \quad = \frac{1}{\sinh 2p}.$$

We have proved the following result.

Corollary 1 Angle of Parallelism

Let be a d-line, and P a point of D that does not lie on . Then the angle between the perpendicular from P to (of hyperbolic length p) and either d-line through P that is parallel to is given by

$$\tan \quad = \frac{1}{\sinh 2p}.$$



For example, the hyperbolic distance of the point $\frac{1}{2}i$ from the diameter $= (\quad 1, 1)$ is $\tanh^{1} 0.5 \quad 0.5493$. It follows that the angle between the perpendicular from $\frac{1}{2}i$ to and either parallel to through $\frac{1}{2}i$ is given by

$$\tan \quad = \frac{1}{\sinh\ 2\tanh^{1} 0.5}$$
$$\frac{1}{\sinh 1.0986};$$

hence, 0.6435 radians.

In fact, the remarkable formula

$$\sinh\ 2\tanh^{1} x \quad = \frac{2x}{1 \quad x^2}$$

gives tan $= \frac{3}{4}$ exactly.

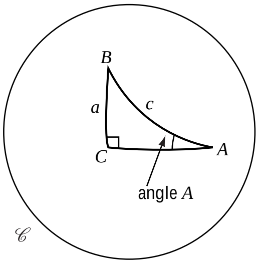
Problem 10 Determine the angle between the perpendicular from the point $\frac{3}{4}$ to the d-line with equation $x = 0$ and either parallel to through $\frac{3}{4}$.

Finally we give, without proof, another useful formula.

Theorem 10 Sine Formula
Let ABC be a d-triangle right-angled at C. Let a and c be the hyperbolic lengths of BC and AB. Then

$$\sin A = \frac{\sinh 2a}{\sinh 2c}.$$

A proof of this result will be found as an Exercise in Section 6.7.



Remark

This result agrees with the expected one when the triangle is small, for in such cases $\sinh 2a \quad 2a$ and $\sinh 2c \quad 2c$, so $\sin A \quad a/c$, which is the Euclidean result.

Problem 11 Use the Sine Formula to find the length a of the sides of a hyperbolic equilateral triangle ABC with angle , as a function of .
Hint: Apply the Sine Formula to the triangle obtained by dropping the perpendicular AD from A to BC.

Proofs

We now supply proofs of two results that you met earlier in this subsection.

The formulas in Theorems 8 and 9 depend on the following remarkable formula:

$$\cosh \quad 2\tanh \quad ^{1} x \quad = \frac{1+x^2}{1 \quad x^2}. \tag{4}$$

The substitution $x = \tanh t$ shows that equation (4) holds if and only if

$$\cosh 2t = \frac{1+\tanh^2 t}{1 \quad \tanh^2 t},$$

and this formula follows from the definitions of cosh and tanh, as you can check.

For future convenience, we now list various expressions that we have now met for the inverse tanh function.

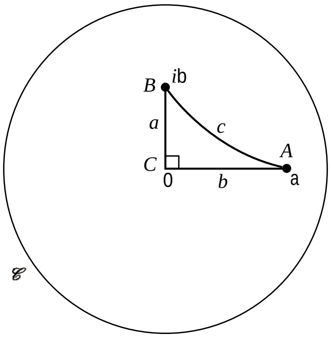
For $x \quad (\quad 1, 1)$, the following are all equal to $\tanh \quad ^{1} x$:

$$\frac{1}{2}\log_e \frac{1+x}{1 \quad x}, \ \frac{1}{2}\sinh \quad ^{1} \frac{2x}{1 \quad x^2}, \ \frac{1}{2}\cosh \quad ^{1} \frac{1+x^2}{1 \quad x^2}.$$

Theorem 8 Pythagoras' Theorem
Let ABC be a d-triangle in which the angle at C is a right angle. If a, b and c are the hyperbolic lengths of BC, CA and AB, then

$$\cosh 2c = \cosh 2a \times \cosh 2b.$$

Proof To prove Pythagoras Theorem in hyperbolic geometry, by the Origin Lemma we may assume that C is at the centre of D, the point A is at the point a on the horizontal diameter and the point B is at ib on the vertical diameter, where a and b are real and positive.



Here a, b, c are real because they are the hyperbolic lengths of the sides of the d-triangle ABC.

From the Distance Formula, it follows that

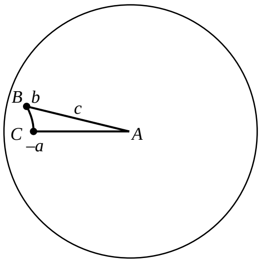
$$a = \tanh^{1} b \quad \text{and} \quad b = \tanh^{1} a . \tag{5}$$

We now map D to itself by the hyperbolic transformation

$$M(z) = \frac{z \quad a}{1 \quad a z}.$$

Under M, A goes to the origin (which we shall also call A, for clarity), B goes to the point B, with complex coordinates

$$b = \frac{ib \quad a}{1 \quad ia b},$$



and C goes to the point C, with coordinates a.

Because the hyperbolic transformation preserves lengths, the hyperbolic length c of AB is equal to the hyperbolic length of $A B$.

To find c, the hyperbolic length of AB, we first find the modulus of b. We calculate its square:

$$|b|^2 = \frac{|ib \quad a|^2}{|1 \quad ia b|^2} = \frac{a^2 + b^2}{1 + a^2 b^2}. \tag{6}$$

Now we observe from formula (4) and equation (5) above that

$$\cosh 2a = \cosh \quad 2 \tanh^{1} b \quad = \frac{1 + b^2}{1 \quad b^2},$$

$$\cosh 2b = \cosh \quad 2 \tanh^{1} a \quad = \frac{1 + a^2}{1 \quad a^2};$$

also, since $c = \tanh^{1} |b|$, we get from the formula (4) that

$$\cosh 2c = \cosh \quad 2 \tanh^{1} |b| \quad = \frac{1 + |b|^2}{1 \quad |b|^2}.$$

But, it then follows from equation (6) that

$$\cosh 2c = \frac{1+|b|^2}{1-|b|^2} = \frac{1+\frac{a^2+b^2}{1+a^2b^2}}{1-\frac{a^2+b^2}{1+a^2b^2}}$$

$$= \frac{1+a^2+b^2+a^2b^2}{1-a^2-b^2+a^2b^2}$$

$$= \frac{1+b^2}{1-b^2} \times \frac{1+a^2}{1-a^2},$$

$$= \cosh\left(2\tanh^{-1} b\right) \times \cosh\left(2\tanh^{-1} a\right)$$

$$= \cosh 2a \times \cosh 2b.$$

This proves the analogue of Pythagoras' Theorem in hyperbolic geometry.

Theorem 9 Lobachevskii's Formula
Let the d-triangle ABC have a right angle at C, and let the hyperbolic lengths of sides AC and BC be b and a, respectively. Then

$$\tan A = \frac{\tanh 2a}{\sinh 2b}.$$

Proof We proceed as in the proof of Theorem 8, by mapping the d-triangle ABC with vertices at a, ib and 0, respectively, by the hyperbolic transformation $M(z) = \frac{z-a}{1-az}$ onto the d-triangle with vertices at 0,

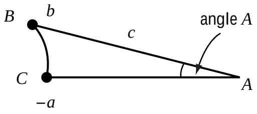
$$b = \frac{ib-a}{1-iab} = \frac{-a\left(1+b^2\right)+ib\left(1-a^2\right)}{1+a^2b^2} \qquad (7)$$

We obtain the second fraction in equation (7) by multiplying the numerator and denominator of the first fraction by $1 + iab$.

and $-a$, respectively, where $b = \tanh^{-1} a$ and $a = \tanh^{-1} b$, so that

$$a = \tanh b \quad \text{and} \quad b = \tanh a.$$

The mapping also sends the angle A in ABC onto an angle of equal size (which we also denote by A by a slight abuse of notation) at the origin. Since the triangle with vertices at $0, b$ and $-a$ is right-angled at $-a$, it follows from equation (7) that



$$\tan A = \frac{b\left(1-a^2\right)}{a\left(1+b^2\right)}. \qquad (8)$$

Now, since $a = \tanh b$, we can write

$$\frac{1\quad a^2}{a} = \frac{1\quad \tanh^2 b}{\tanh b}$$

$$= \frac{\cosh^2 b\quad \sinh^2 b}{\sinh b \bullet \cosh b} = \frac{2}{\sinh 2b}.$$

Here we use the identities

$$\cosh^2 x\quad \sinh^2 x = 1$$

and

$$\sinh 2x = 2\sinh x \cosh x$$

for x R.

Similarly, we can verify that

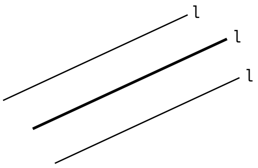
$$\frac{b}{1+b^2} = \tfrac{1}{2}\tanh 2a.$$

Hence, if we substitute these expressions for $\frac{1\ \ a^2}{a}$ and $\frac{b}{1+b^2}$ into equation (8), we find that

$$\tan A = \frac{\tanh 2a}{\sinh 2b}.$$

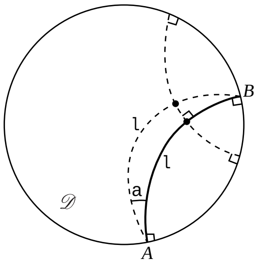
6.4.4 Equidistant Curves to *d*-Lines

In the Euclidean plane R^2, the set of points at a fixed distance from a given line is a pair of straight lines parallel to . In the hyperbolic disc D there are two curves equidistant from a given *d*-line, though neither is itself a *d*-line.



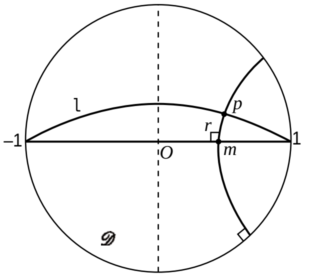
Theorem 11 Let be a *d*-line that ends at points *A* and *B* on C, and let be that part in D of a (Euclidean) circle through *A* and *B*, and let be the angle (in D) between and . Then all points on are the same hyperbolic distance *d* from , where

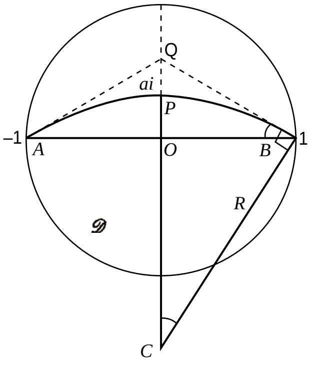
$$d = \tfrac{1}{2}\log_e \quad \tan \quad \frac{\ }{2} + \frac{\ }{4} \quad .$$



Proof First, map C and D to themselves by a Möbius transformation *M* that maps *A* and *B* to 1 and 1 (not necessarily respectively) and maps to a curve in the upper half of D. Since Möbius transformations preserve angles and generalized circles, it follows that the image of the *d*-line *AB* is the diameter [1, 1], and the image of is an arc of a circle in the upper half of D through −1 making an angle (in D) with [1, 1].

It is not hard to verify that such an *M* exists.





In view of the above remarks, it is sufficient to assume that the d-line is the diameter $(\quad 1, 1)$ of D. Let p be a point on , and m the foot of the perpendicular r from p to $(\quad 1, 1)$. Let M_1 be the Möbius transformation defined by

Similarly, we shall refer below to rather than to $M(\quad)$.

$$M_1(z) = \frac{z \quad m}{1 \quad mz}.$$

Then M_1 maps D to itself, and $(\quad 1, 1)$ to itself. It maps m to 0, to an arc of a (Euclidean) circle, with radius R and centre C (say), through -1; and it maps r to a portion of a d-line through O that is perpendicular to $(\quad 1, 1)$ and so to a portion of the imaginary axis. It follows that the point $P = M_1(p)$ is of the form ai, for some real number $a \quad (\quad 1, 1)$. Since M_1 is a hyperbolic transformation it does not alter hyperbolic distances, so that

Property 6, Subsection 6.3.1

$$\begin{aligned} d(p, m) = d(0, ai) &= d(0, a) \\ &= d, \text{ say.} \end{aligned}$$

Now, if Q is the point where the perpendicular to CB at B meets OC, the triangles CBQ and BOQ are similar, since $CBQ = \frac{}{2} = BOQ$ and $BCQ = OQB$. It follows that $BCQ = OBQ =$. Also, from OBC we see that $R \sin \quad = OB = 1$. Hence

Here we use the identities

$$\cos 2x = 1 \quad 2\sin^2 x$$

and

$$\sin 2x = 2 \sin x \cos x$$

for x R.

$$\begin{aligned} a &= R \quad R\cos \\ &= \frac{1 \quad \cos}{\sin} \\ &= \frac{2\sin^2 \frac{}{2}}{2\sin \frac{}{2} \cos \frac{}{2}} = \tan \frac{}{2} \; . \end{aligned}$$

It follows that

Recall from equation (3) of Subsection 6.3.1 that

$$\tanh^{\;1} k = \tfrac{1}{2} \log_e \frac{1 + k}{1 \quad k}$$

for any $k \quad 0$.

$$\begin{aligned} d = \tanh^{\;1} a &= \tanh^{\;1} \tan \frac{}{2} \\ &= \tfrac{1}{2} \log_e \frac{1 + \tan \frac{}{2}}{1 \quad \tan \frac{}{2}} \\ &= \tfrac{1}{2} \log_e \tan \frac{}{2} + \frac{}{4} \quad . \end{aligned}$$

This completes the proof of the theorem.

For example, the portion in the upper half of D of the Euclidean circle through -1 that makes an angle of $/4$ with the segment $[\quad 1, 1]$ is a set of points equidistant in D from $[\quad 1, 1]$, with the distance of separation being

$$d = \frac{1}{2} \log_e \tan \frac{}{8} + \frac{}{4} = \frac{1}{2} \log_e \tan \frac{3}{8} \qquad 0.4407.$$

6.5 Area

6.5.1 Area of a *d*-triangle

In the Euclidean plane $\mathbb{R}^2$, the area of a set is defined in terms of the union of areas of small rectangles. In the hyperbolic disc $\mathbb{D}$ the situation is somewhat different; *d*-quadrilaterals cannot have four right angles and so do not conveniently exhaust areas in an analogous way.

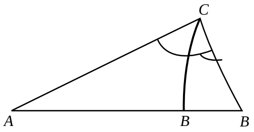
Theorem 2, Subsection 6.4.1

We want our definition of area in hyperbolic geometry to have such properties as the following:

The area of a *d*-triangle is non-negative, and is zero only if its Euclidean area is zero;
d-congruent *d*-triangles (and *d*-congruent asymptotic *d*-triangles) should have the same area;
if one *d*-triangle can be fitted inside another, it should have smaller area;
area should be additive.

Then we can determine the area of any figure in $\mathbb{D}$ that can be divided up into *d*-triangles.

Throughout this subsection, all lines and line segments will be *d*-lines and *d*-line segments, but to avoid constant repetition we will simply drop the *d* .



Notice first that as *d*-triangles grow in size their angle sum decreases. For example, let *ABC* be contained in *AB C*, where *A*, *B* and *B* are collinear, as shown. Denote by , , and , , the angles of the two *d*-triangles, as shown. Consider the *d*-triangle *BCB* . The angles at *B* and *C* in this are and . Then, since the sum of the angles of a *d*-triangle is less than , it follows that

Theorem 1, Subsection 6.4.1

$$(\quad) + (\quad) + \quad < \quad ,$$

so that $+ \; > \; +$; hence $+ \; + \; > \; + \; +$, as asserted.

Problem 1 Prove that a trebly asymptotic *d*-triangle can be divided into two doubly asymptotic right-angled *d*-triangles.
Hint: Consider a new vertex sliding along one edge; how do the angles vary?

Now, since very small *d*-triangles are *d*-congruent to small *d*-triangles near the origin, where *d*-lines are approximately Euclidean lines, the sum of the angles of very small *d*-triangles is close to .

At the opposite end of the size scale, we can use the result of Problem 1 above to prove the surprising fact that all trebly asymptotic *d*-triangles are *d*-congruent to each other.

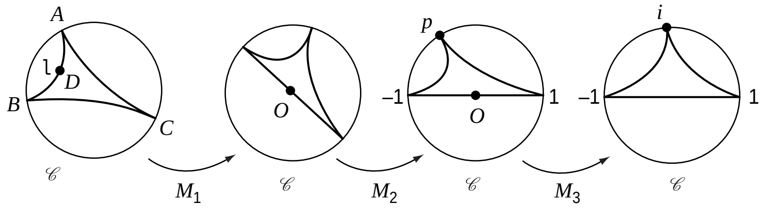
Theorem 1 below

Theorem 1 All trebly asymptotic *d*-triangles are *d*-congruent to each other.

Proof It is sufficient to prove that trebly asymptotic d-triangles are d-congruent to the trebly asymptotic d-triangle with vertices -1, 1 and i.

So, let $\triangle ABC$ be any trebly asymptotic d-triangle, where (for convenience) we assume that the vertices A, B, C occur in clockwise order on $\mathbb{C}$. Let ℓ denote the line AB, and let D be any point of ℓ in $\mathbb{D}$.

Then, by the Origin Lemma, we can map $\mathbb{D}$ to itself and D onto the origin O by a Möbius transformation, M_1 say. It follows that M_1 maps AB onto a diameter of $\mathbb{D}$.



We can then map $\mathbb{D}$ to itself by another Möbius transformation, M_2 say, that rotates the disc about the origin and maps A and B onto -1 and 1, respectively. Since Möbius transformations are direct hyperbolic transformations, they preserve the orientation of points; it follows that the image of C under $M_2 \circ M_1$ is some point p, say, on the upper half of $\mathbb{C}$.

Now, for any real number $m \in (-1, 1)$, the Möbius transformation

$$M_3(z) = \frac{z - m}{1 - mz}$$

maps $\mathbb{D}$ to $\mathbb{D}$, $\mathbb{C}$ to $\mathbb{C}$, -1 to -1, 1 to 1, and the upper halves of $\mathbb{D}$ and $\mathbb{C}$ to themselves. It also maps p to i if m is chosen so that

$$i = \frac{p - m}{1 - mp},$$

which we can rewrite in the form

$$m = \frac{p - i}{1 - pi}. \tag{1}$$

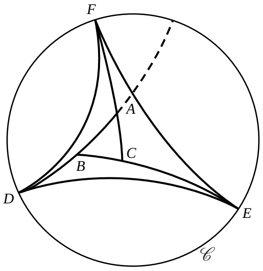
Then, using the facts that $|p| = 1$ and $\operatorname{Im} p > 0$, we can check that equation (1) indeed provides a value of m that is real and strictly between -1 and 1.

We omit the details.

Composing the three Möbius transformations that we have met, the composite Möbius transformation $M_3 \circ M_2 \circ M_1$ maps the trebly asymptotic d-triangle $\triangle ABC$ onto the trebly asymptotic d-triangle with vertices -1, 1 and i, as required.

Trebly asymptotic d-triangles will play a crucial role in our discussion of hyperbolic area. First, we see that every d-triangle can be fitted inside some trebly asymptotic d-triangle.

Theorem 2 Let ABC be a d-triangle. Then there exists a trebly asymptotic d-triangle DEF that contains ABC.



Proof First, we construct a trebly asymptotic d-triangle DEF as follows: extend the segment AB beyond B to meet C at D, the segment BC beyond C to meet C at E, and the segment CA beyond A to meet C at F. Then draw the trebly asymptotic d-triangle DEF.

Now, the d-line containing the points A, B, D cuts off a minor arc of C that contains F. It follows that the d-line through D and F lies on that side of the d-line through A, B, D, and (in particular) that the d-triangles DAF and ABC do not overlap.

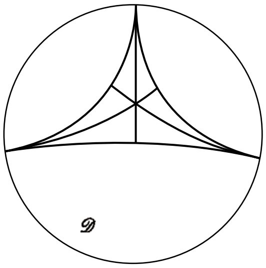
Similarly, the d-triangles EBD and ABC do not overlap, and also the d-triangles FCE and ABC do not overlap. Also, none of the d-triangles DAF, EBD, FCE overlap.

It follows that ABC is contained within DEF, as required.

Then, since every d-triangle can be fitted inside some trebly asymptotic d-triangle, the following completely surprising result (which holds whatever our definition of hyperbolic area is) proves the existence of an upper bound for the area of all d-triangles.

Theorem 3 All trebly asymptotic d-triangles have the same (hyperbolic) area, and this is a finite number.

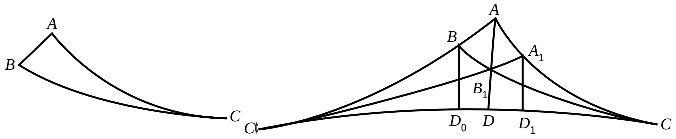
Note that the area must be finite, whatever definition of hyperbolic area we choose to use.



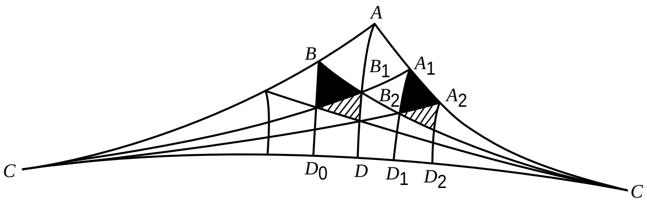
Proof Using the result of Problem 1, we can divide a given trebly asymptotic d-triangle into six singly asymptotic d-triangles, as shown in the margin diagram. Therefore it is sufficient to prove that the area of a singly asymptotic d-triangle is finite.

Let ABC be a singly-asymptotic d-triangle, with C on C (as in the left figure below). First, extend AB to meet C at a point C , and bisect BAC by AD, where D is a point on CC . Next, (hyperbolically) reflect BAC in AD; since AB has finite hyperbolic length and AC has infinite hyperbolic length (since C lies on C), this reflection maps B to some point A_1, say, on AC, as shown in the right diagram below. Also, the reflection must map BC onto A_1C ; and, by symmetry, BC and A_1C must meet at some point, B_1 say, on AD.

Next, bisect C BC by BD_0, where D_0 is on C C, and bisect C A_1C by A_1D_1, where D_1 is on C C, as shown below.



Our strategy of proof is now as follows. The d-pentagon $AA_1D_1D_0B$ and its boundary all lie in D, and so at a minimum positive distance from C, the boundary of D. Also, by adding additional line segments B_1D_0 and B_1D_1 we can divide the d-pentagon into eight d-triangles; each d-triangle has finite area, and so the d-pentagon must also have finite area. We will show that BAC can be cut up and reassembled (iteratively) inside this d-pentagon, and so has an area less than or equal to the area of the d-pentagon; in particular, it must have finite area.



We now do to B_1A_1C what we did previously to BAC. Reflect (in a hyperbolic way) B_1A_1C in A_1D_1 : B_1 maps to some point A_2 on A_1C and B_1C maps to A_2C , which meets B_1C at some point B_2 on A_1D_1.

$B_2A_1A_2$ is congruent to several d-triangles in the d-pentagon; for convenience we choose the black one on the left in the figure above. We then repeat the process for B_2A_2C. We bisect B_2A_2C with A_2D_2, where D_2 is some point on $C C$. The cross-hatched d-triangles in the above figure are d-congruent one is in BAC and one is in the d-pentagon.

Continuing indefinitely, we do for $B_{n+1}A_{n+1}C$ what we have just done for B_nA_nC. With each pair of hyperbolic reflections we get two new d-triangles in BAC and two new d-triangles in the d-pentagon. These d-triangles are d-congruent by means of a sequence of hyperbolic reflections in the d-lines $A_{n+1}D_{n+1}, A_nD_n, \ldots, A_1D_1$ and AD.

In this way, we reassemble the asymptotic d-triangle *inside* the d-pentagon; hence the asymptotic d-triangle must have finite area.

It follows that all trebly asymptotic d-triangles have finite area, and so (as we noted before the theorem that all trebly asymptotic d-triangles are d-congruent) they have the same area.

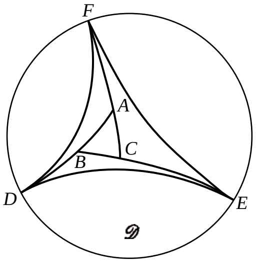
Problem 2

(a) Prove that a doubly asymptotic d-triangle is a subset of a suitably chosen trebly asymptotic d-triangle, and so is finite.

(b) Prove that the area of a doubly asymptotic d-triangle depends only on the angle at its vertex in D.

We can now give Gauss magnificent proof that the area of each d-triangle is proportional to the quantity

$$\qquad \text{(angle sum)}.$$



Problem 2, part (b)

Theorem 4 The area of a d-triangle with angles , , is given by $K($ $(\ + \ + \ ))$, where K is the same constant for all d-triangles.

Proof Let ABC be a d-triangle with angles , , at vertices A, B, C, respectively. Extend the line segment AB to a point D on C, the segment BC to a point E on C, and the segment CA to a point F on C. Since DEF is trebly asymptotic, it has finite area, k say, by Theorem 3.

Now, we have seen that any doubly asymptotic d-triangle has an area which depends only on the angle at its vertex in D, and so only on the exterior angle of the triangle at its vertex in D. So, we define a function f such that the area of any doubly asymptotic d-triangle with exterior angle , say, in D is $f(\ )$.

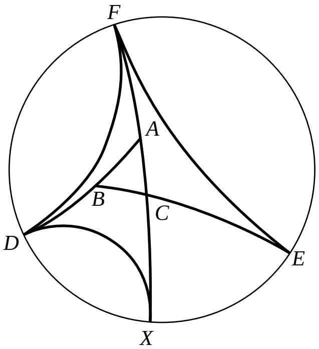
Then, it is clear from the margin figure above that in FAD this exterior angle equals ; so, the (hyperbolic) area of FAD is $f(\ )$.

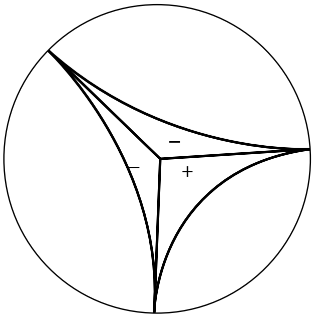
If the segment FAC extended meets C at X (as in the left figure below), then DXF is trebly asymptotic and is composed of the two doubly asymptotic d-triangles FAD and DAX. Then, if we denote the area of each trebly-asymptotic d-triangle (such as DXF) by k, say, and notice that (from our definition of f) the area of DAX is $f(\qquad)$ since its exterior angle at A is , it follows that

$$k = f(\ ) + f(\qquad). \qquad (2)$$

Here we use the fact that (hyperbolic) area is additive.

Our next objective is to use equation (2) to determine an explicit formula for f.





So, consider any trebly asymptotic d-triangle, as shown in the figure on the right above. By drawing radii from the center of D to its vertices on C, we can divide this d-triangle into three doubly asymptotic d-triangles. If we denote the angles at O of these three d-triangles by , and + , as shown above, we have

$$k = f(\ ) + f(\ ) + f(\qquad (\ + \ ))$$

By equation (2), $f(\quad (\ +\ )) = k \quad f(\ +\ )$, so that

$$f(\ ) + f(\ ) + k \quad f(\ +\ ) = k,$$

that is,

$$f(\ ) + f(\ ) = f(\ +\ ). \qquad (3)$$

It follows from equation (3) that f is linear, so that $f(\ ) = \quad$ for some constant .

We omit the details of this fact, which uses a continuity argument.

Using this formula for f, we deduce from equation (2) that

$$(\ ) + \ (\qquad) = k,$$

so that $= \frac{k}{\ }$. Hence $f(\ ) = \frac{k}{\ }$.

Returning to the original d-triangle ABC in the margin figure above, the area of ABC is equal to the area of DEF minus the sum of the areas of the three doubly asymptotic d-triangles FAD, DBE and CAF. Since the latter four areas are k, $f(\ )$, $f(\ )$ and $f(\ )$, respectively, it follows that

We again use the fact that (hyperbolic) area is additive.

$$\text{area of } ABC = k \quad (f(\ ) + f(\ ) + f(\ )).$$

Using the formula for f that we have just found, we can write this equation as

$$\text{area of } ABC = k \quad \frac{k}{\ } + \frac{k}{\ } + \frac{k}{\ } \quad ,$$

and so as

$$\text{area of } ABC = K(\quad (\ +\ +\ )),$$

where $K = k$.

Note that here K is arbitrary.

It is usual to take $K = 1$ (which is equivalent to taking the area of a trebly asymptotic d-triangle to be). Then

$$\text{area of } ABC = \quad (\ +\ +\ ).$$

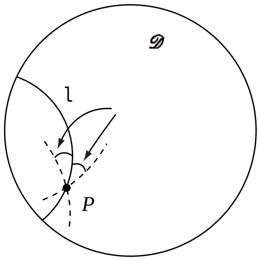
The expression $(\ +\ +\ )$ is called the *angular defect* of ABC.

Now this result is all very well, but how do we know whether, given any positive real numbers , , with $+\ +\ <$, there actually is a d-triangle whose angles are , , ?

Recall that, if , , are positive real numbers with $+\ +\ =$, then such a Euclidean triangle exists.

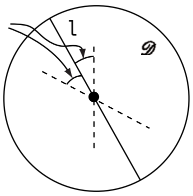
A key tool in showing that such a d-triangle exists, is the following result.

Lemma 1 Let P be a point on a d-line of D, and let $0 < \quad < \frac{}{2}$. Then there are exactly two d-lines through P that make an acute angle with , and each is a (hyperbolic) reflection of the other in .



Proof Since all the properties in the statement of the Lemma are hyperbolic properties, and there is a hyperbolic transformation (for example, a Möbius transformation) that maps the point P to the origin O, it is sufficient to prove the result when P is the origin.

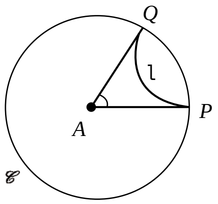
Then there are (by Euclidean geometry) exactly two diameters of D (and diameters are *d*-lines) through the origin that make an acute angle with the given diameter , and each is a reflection of the other in . This completes the proof.



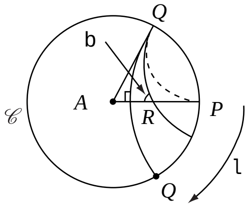
We are now in a position to prove the final result in this subsection.

Theorem 5 Let , , be positive real numbers with $0 < \; + \; + \; < \;$. Then there is a *d*-triangle in D with angles , , .

Proof Since $0 < \; + \; + \; < \;$, at least one of the numbers lies strictly between 0 and $\frac{}{2}$; let us suppose that this number is . Next, let *A*, *P*, *Q* be the points in D with coordinates 0, 1, cos + *i* sin , and let be a variable *d*-line in D whose initial position is as the *d*-line with endpoints *P* and *Q*. Then the angles of the doubly-asymptotic *d*-triangle *APQ* are , 0 and 0.

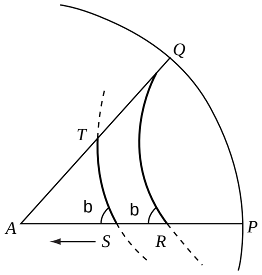


The first step is to keep fixed the endpoint of that is originally at *Q*, and let the endpoint that is originally at *P* move round C away from *Q*. As this endpoint moves away from *P*, the angle between and the radius *AP* varies continuously, starting at 0. By the time that the moving endpoint reaches *Q* , the image of *Q* under Euclidean reflection in the radius *AP*, the angle has reached the value $\frac{}{2}$. It follows, by continuity and the intermediate value property, that there is some point, *R* say, on *AP* such that for the *d*-line through *P* and *R* the corresponding value of the angle is .

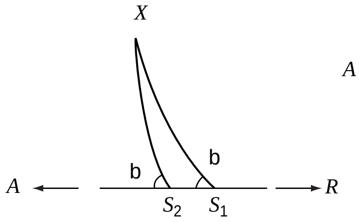


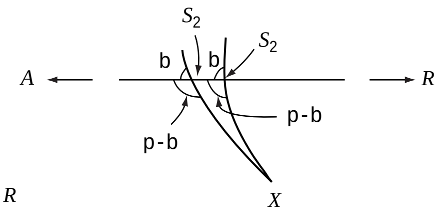
Now, it follows from Lemma 1 that through every point *S* between *A* and *R* there is a *d*-line that makes an angle with the radius *AP*; also, if we assume that this angle lies above the radius *AP* and contains part of the second quadrant of D in its interior, this *d*-line is unique.

We now let *S* move along *AP* from *R* towards *A*, taking with it the corresponding *d*-line . Denote by *T* the point where the variable *d*-line intersects the radius *AQ*. Then, as *S* moves along *AP* from *R* towards *A*, *T* moves along *AQ* from *Q* towards *A*.



The *d*-lines $_1$ and $_2$ corresponding to successive positions S_1 and S_2 of *S* do not meet in D. For, if they met at a point *X* in D, then the external angle at S_2 of the *d*-triangle XS_1S_2 would be less than or equal to the sum of the opposite two internal angles, which is impossible by the result of Problem 1 in Subsection 6.4.1. (The following figure shows the situation when *X* is in the upper/lower half of D, respectively.)





Hence as S moves monotonically along AP from R towards A, T moves monotonically along AQ from Q towards A. As S approaches A, the curvature of the d-line decreases, and approaches the diameter d of D that makes an angle with the diameter containing AP.

As T moves monotonically along AQ from Q towards A, the angle at T between the radial line AT and starts at 0, and approaches the value (+) as T approaches A. It follows, by continuity and the intermediate value property, that there is some point, C say, on AQ such that at C the d-line makes an angle with the radius through C.

If we denote by B the point where the d-line through C meets AP, then the triangle ABC has the desired angles , , .
